Toxicological test for mercury. KOHN-ABREST. *Ann. chim. anal. chim. appl.* **7**, 353-5(1925).—To 100-200 g. of finely divided material, add a little water to form a fluid paste, 0.1 the original wt. of KClO₃ and 0.2 the original wt. of concd. HCl. Heat until the org. matter is destroyed, taking the precaution to pass the evolved gas into water to catch any HgCl₂ that may distil off. Unite the 2 solns. and treat with H₂SO₄ to reduce the excess of KClO₃ and any arsenate that may be present. Ppt. HgS, Sb₂S₃ and As₂S₃ by means of H₂S. Use a part of the ppt. to test for As and Sb and the remainder for Hg. To test for Hg, dissolve in aqua regia, evap. off the excess acid in the cold, using a vacuum and dissolve the residue in warm water. Filter and make the filtrate slightly acid with HCl. Introduce a brass spiral to ppt. Hg. If there is any deposit, heat in a glass tube to distil off the Hg, collecting it in a cold part of the tube. By means of I₂ vapors change the gray deposit to red iodide. Dissolve the HgI₂ in 1 cc. of 1% KI soln., add 1 cc. of slightly ammoniacal gum arabic and 1 cc. of satd. H₂S soln. Mix and compare the color produced with that obtained similarly with known amts. of Hg. W. T. H

Determination of nitrogen in industrial products. V. EDWARDS. *Ind. Chemist* **1**, 122-3(1925).—Stress is laid on the usefulness and convenience of Kjeldahl's method. A detailed description of the Kjeldahl-Gunning method (CuSO₄ in place of Hg, however, and some points to be observed in the Jodlbauer method (using phenol) are given. The phenol-H₂SO₄ should be poured on quickly, especially when ammonium salt and nitrate are both present. If the nitric N is appreciable E. recommends detn. first of the NH₄ and org. N by the Kjeldahl-Gunning method and then on a sep. portion to apply E.'s modification of the Pelouze method (Sutton's Vol. Analysis, 11th ed.) in which the Fe soln. is boiled till viscid, then dild., cooled and titrated with K₂Cr₂O₇. The Jodlbauer method gives almost correct results with NH₄NO₃, KNO₃, urea nitrate, C₆H₅NO, nitronaphthalene, nitroaniline, picric acid, dinitrobenzene and K *p*-bromochloronitrophenol. The ordinary Kjeldahl-Gunning method gives good results with quinine, strychnine, aniline, atropine, diphenylamine, naphthylamine, pyridine, benzidine and aldehyde-ammonia. E. G. R. ARDAGH

Kjeldahl-Pregl method applied to nitro compounds. ADALBERT ELEK AND HARRY SOBOTKA. *J. Am. Chem. Soc.* **48**, 501-3(1926).—A micro-Kjeldahl method is described using 3-10 mg. of the sample, 50-100 mg. glucose, 1 g. K₂SO₄, a small crystal of CuSO₄, and 3 cc. H₂SO₄, which gives satisfactory results in the detn. of N in nitro, azo and similar compds. C. J. WICK

Estimation of nitrate-nitrogen by a modification of Kjeldahl's method. S. K. DEB. *Ind. Chemist* **1**, 452-3(1925).—A series of results indicates the suitability of the Kjeldahl method for the detn. of total N when Na₂S₂O₃ and thiosalicic acid are used for the reduction of nitrates. W. T. H

The quickest micro-method for determining nitrogen. A. KULTJUGIN AND I. GUBAREFF. *Biochem. Z.* **164**, 437-41(1925).—In N detns. by ashing with H₂SO₄ there is a source of error due either to insufficient heating or to escape of NH₃ if the heating is too prolonged. The use of concd. H₂O₂ obviates this difficulty. The detn. is carried out as follows: transfer 0.5 cc. of the soln. to a test tube and heat with 0.05 cc. concd. H₂SO₄ over a micro-burner until the fumes just appear. Cool and add 0.03 cc. of perhydrol. Heat until H₂SO₄ fumes reappear, and for 15 sec. longer. After cooling, dild. with 15 cc. of doubly distd. H₂O, mix with 0.3 cc. 50% NaOH, and nesslerize with 0.5 cc. reagent. The control is prepd. in such a way that an NH₄Cl soln. contg. 0.05 mg. per cc. is added from a micro-buret until the color produced by nesslerization of the known matches exactly the unknown sample. The quantity of 0.02-0.05 mg. N are detd. A blank on the known with perhydrol is needed as the latter may contain N. S. MORGULIS

Determination of hypoiodites and iodates, hypobromites and bromates, iodates and bromates in the presence of one another. E. SCHULERK. *Z. anal. Chem.* **67**, 142-7 (1925).—To det. iodate in the presence of hypoiodite, add an excess of 5% phenol soln. which reacts with HIO but not with HIO₃, and sat. with CO₂. Then add KI, make acid with H₂SO₄ and titrate with thiosulfate. A similar procedure serves for the detn. of bromate in the presence of hypobromite. To det. iodate and bromate when both are present, add satd. SO₂ soln. until the odor of SO₂ is marked. Heat to boiling for about 10 min. to ensure the complete reduction of iodate and bromate to iodide and bromide. Cool, neutralize with N NaOH and titrate the iodide as previously described (C. A. 19,

2464, method III). In another portion, det. iodate and bromate together by titrating the I_2 liberated with KI in acid soln. W. T. H.

Electrometric titration of phosphate. SVEN BODFORSS. *Svensk Kem. Tids.* **37**, 296-300 (1925).—When PO_4^{---} is titrated electrometrically, the $UO_2(AcO_2)$ method of Pincus being used, a marked change in e. m. f. is noticed at the end point when a $K_4Fe(CN)_6$ -Hg electrode is used instead of Pt. A. R. ROSE

Determination of hydrocyanic acid in gaseous mixtures. G. E. SEILL. *Ind. Eng. Chem.* **18**, 142-3 (1926).—When I_2 reacts with HCN in the presence of $NaHCO_3$, the products are NaI, CNI, CO_2 and H_2O . In acid soln. a mixt. of CNI and HI yields IICN and I_2 . H_2S and I_2 unite to form HI and S. Based on these reactions, it is easy to det. HCN rapidly when present with H_2S . The vol. of I_2 required to react with HCN and H_2S and then the amt. of I_2 liberated on adding HCl are detd. W. T. H.

Theoretical and recorded pressures in oxygen bomb determinations. M. J. BRADLEY, C. Z. ROSECRANS and R. M. CORBIN. *Ind. Eng. Chem.* **18**, 307-9 (1926).—Pressures developed within an Illium O_2 bomb during the combustion of various wts. of crude petroleum, coals, benzene, kerosene and benzoic acid were measured and compared with the calcd. theoretical pressures, account being taken of the variation in the sp. heats of the products of combustion with the temp. and on the assumption that 50% of the heat of combustion is lost before the max. temp. is reached. W. T. H.

Determination of oxygen and hydrogen in metals by fusion in vacuum. LOUIS JORDAN and J. R. ECKMAN. *Ind. Eng. Chem.* **18**, 279-82 (1926).—By means of high-frequency induction it is possible to heat a sample of metal in a receptacle made of refractory oxide or a graphite crucible within a fused-silica vacuum chamber to 2000° while the walls of the silica tube remain sufficiently cool to maintain a good vacuum. Three methods of fusing ferrous alloys were tested: fusion in refractory oxide crucibles, fusion with Sb-Sn alloy and fusion in graphite crucibles, using 100 g. samples in the first case and 30 g. samples otherwise. The values for H_2 , seldom over 0.002%, agreed fairly well by all methods but with O_2 , sometimes over 0.1%, the best values were obtained in a graphite crucible. The absorption train used is suitable for the detn. of H_2O , CO_2 , CO and H_2 passing through the train at low pressures. Also in Bur. Standards, *Sci. Papers* **20**, No. 514, 445-82 (1925). W. T. H.

A colorimetric method for the estimation of hydroxylamine. G. W. PUCHER and H. A. DAY. *J. Am. Chem. Soc.* **48**, 672-6 (1926).—A colorimetric method is described which depends on the reaction of NH_2OH with C_6H_5COCl and $FeCl_3$. W. T. H.

Determination of nicotine in tobacco. HANS RUNDSHAGEN. *Chem.-Ztg.* **50**, 42 (1926).—The Tóth method for the detn. of nicotine has been modified so that it reads as follows: Treat 10 g. of dried tobacco powder with 2 g. powdered KOH and a little water. During 15 min., occasionally triturate to make sure that the nicotine is all released. While stirring with a spatula, add dry $CaSO_4$ until the mass becomes a homogeneous powder when pressed with a pestle. Transfer to a Kjeldahl flask and extract the nicotine with a mixt. of 50 cc. ether and 50 cc. petroleum ether. Close tightly and shake 15 minutes in a shaker. Centrifuge, pour off a part of the clear soln. mixt. through a filter and titrate with 0.1 N H_2SO_4 using iodeosin as indicator. W. T. H.

A modification of Schoorl's titration of sugars. I. M. KOLTHOFF. *Chem. Weekblad* **23**, 61-2 (1926).— Cu_2O is oxidized by KIO_3 -KI in a CO_2 atm.; the excess I is titrated back with $Na_2S_2O_3$. Quant. oxidation is effected by proper diln. and by reducing the Cu^{++} concn. with $K_2C_2O_4$. The method has the advantage of a sharp and permanent end point. MARY JACOBSEN

Determination of anisaldehyde. ÉTABLISSEMENTS A. CHIRIS *Parfums de France No.* **35**, 22 (Jan., 1926).—In the analysis of oils with high anisaldehyde contents or of concentrates obtained in the manuf. of this product, the bisulfite method gives low results because the aldehyde-bisulfite combination, when heated to convert it into sol. sulfonate, is partially (up to 50%) dissociated into aldehyde and bisulfite. To 10 cc. of sample in a 200-cc. aldehyde flask add a 7% Na metabisulfite soln. with const. stirring: the aldehyde dissolves rapidly, giving a clear soln., and the loss in vol. of the oil gives the % by vol. of aldehyde. Analysis of mixts. of known compn. of pure anisaldehyde with hydrocarbons, both alone and with anethole, have shown the method to be reliable. A. PAPINEAU-COUTURE

Measurements with the quinhydrone electrode. K. LINDERSTRÖM-LANG. *Compt. rend. trav. lab. Carlsberg* **16**, No. 3, 24 pp. (1925).—In detg. the H-ion concn. with the Büllman quinhydrone electrode in protein solns. contg. $(NH_4)_2SO_4$, it was found that the method was not unduly tedious and that the results are reproducible. It was desirable,

however, to det. the actual errors involved and this led to a series of expts which represents new detns. of the p. d. between the H electrode and the quinhydrone electrode in HCl-KCl solns. and in NaCl solns. as well as a study of the errors caused by protein and $(\text{NH}_4)_2\text{SO}_4$. For practical reasons it is not easy to det. directly the e. m. f. of the element Pt | quinhydrone | water | H_2 at 1 atm. | Pt at 18° but from the values obtained with HCl solns. of varying concn., the value with pure water is estd. to be 0.70475 ± 0.00005 v. The divergence between this value and that obtained previously by other investigators is probably due to the fact that there is a considerable electrolytic effect even with very dil. HCl and KCl. The alteration in the e. m. f. caused by adding NaCl when 0.01 N HCl replaces the water in the above element was detd. anew. Thus, when the NaCl was 0.5 N, the value became 0.70345, 0.1 N = 0.70199, 2 N = 0.69896, 3 N = 0.69581 and 4 N = 0.69223. It may be noted that the alteration caused at the lower concns. takes a course differing from that obtained later. In this respect NaCl behaves like KCl, the variation in the e. m. f. in dil. solns. being greater than that calcd. from soly. measurements. The alteration in the e. m. f. caused by $(\text{NH}_4)_2\text{SO}_4$ was found to be opposite to that caused by NaCl. The alterations caused by proteins such as casein, egg albumin and serum albumin were found to depend on the nature of the protein and sometimes also upon the acidity of the soln. The following formulas are given for the calcn. of p_{H} and $p_{a\text{H}}$ from measurements of the quinhydrone electrode: $p_{\text{H}} = [(0.36675 - E_{\text{Kln}})/0.0577] + Q$ and $p_{a\text{H}} = [(0.36905 - E_{\text{Kln}})/0.0577] + Q$, in which E_{Kln} is the e. m. f. corrected for the liquid junction potential of the element Pt | quinhydrone | titrated soln. | 3.5 N KCl | 0.1 N KCl calomel electrode at 18° and Q is the correction for the influence of dissolved substances as given in this paper for various concns. of HCl, NaCl, $(\text{NH}_4)_2\text{SO}_4$, egg albumin, serum albumin and casein.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

Symmetry and forms of the diamond. G. FRIEDEL. *Soc. Geol. Belg. Livre jubilaire 1874-1924*, 141-56 (1925).—The object of this study was to det. whether the diamond is holohedral or antihemihedral. The weight of evidence is in favor of the provisional conclusion that it is holohedral.

Realgar from Långban. G. AMINOFF. *Geol. För. Förh.* 47, 344-5 (1925).—Crystals 3-8 mm. in size have been found at Långban, probably the first find in Sweden.

W. SIEGBLOM

Penroseite and truedellite: two new minerals. S. G. GORDON. *Proc. Acad. Natural Sci. Phila.* 77, 317-24 (1925).—Penroseite contains: Se 59.80, Ag 2.04, Pb 17.13, Cu 7.84, Ni 11.14, Co 1.34, Fe_2O_3 1.08, sum 100.37%. Its formula is possibly $2\text{PbSe} \cdot 3\text{Cu}_{2\text{e}} \cdot 5(\text{Ni}, \text{Co})\text{Se}_2$ or $\text{PbSe} \cdot \text{Cu}_2\text{Se} \cdot 3(\text{Ni}, \text{Co})\text{Se}_2$. Truedellite is uniaxial -, with $\epsilon = 1.495$, $\omega = 1.560$ ($\lambda = 579$); analysis gave: SiO_2 0.57, Al_2O_3 25.67, Fe_2O_3 1.00, CuO 1.56, MgO 0.66, Na_2O 1.58, SO_3 13.60, Cl 24.42, H_2O 36.60, less O = Cl, 5.49, sum 100.17%. Its formula is thus $\text{Al}_2(\text{SO}_4) \cdot 4\text{AlCl}_3 \cdot 4\text{Al}(\text{OH})_3 \cdot 30\text{H}_2\text{O}$. J. F. SCHAIERER

A new oxide mineral from Långban, magnetoplumbite. G. AMINOFF. *Geol.*

För. Förh. **47**, 283-9(1925).—This mineral crystallizes hexagonal but without indication of hemihedrism. The crystals are terminated with sharp pyramids. (0001):(10 $\bar{1}$ 1) = 77° 34'. Its cleavage is (0001), hardness about 6, color black, luster metallic, streak dark brown, and it is strongly magnetic. It is sol. with difficulty in HCl; sp. gr. = 5.517. Analysis gave: PbO 19.74, TiO₂ 4.82, Fe₂O₃ 54.65, Al₂O₃ 0.88, Cr₂O₃ 0.05, MnO 17.33, CaO 0.35, MgO 0.47, K₂O 0.14, Na₂O 0.16, H₂O 0.26, SiO₂ 0.15, SiO₂ (insol. in HCl) 0.21, other substances insol. in HCl 0.31, sum 99.52%. Deducting the SiO₂, the part insol. in HCl, and the H₂O and recalculating gives: PbO 20.02, MnO 17.58, CaO 0.36, MgO 0.48, Fe₂O₃ 55.43, Cr₂O₃ 0.05, Al₂O₃ 0.89, TiO₂ 4.89, K₂O 0.14, Na₂O 0.16, sum 100.00%, so that the probable formula is PbO.2Fe₂O₃. W. SERGERBLOM

Quenselite, a new mineral from Långban. G. FLINK. *Geol. För. Förh.* **47**, 377-84 (1925).—Quenselite is number 333 in the Långban list. Crystals are about 1 mm. in diam.; sp. gr. = 6.842; hardness = 2.5. The color is pitch black with metallic or adamantine luster, the powder dark brownish gray. It is sol. in weak acids. Compn. = PbO 69.51, Fe₂O₃ 0.39, MnO 23.21, CaO 0.97, MgO 0.30, K₂O 0.17, Na₂O 0.28, CO₂ 0.64, O 2.38, H₂O 3.02, sum 100.87%. The formula is probably 2PbO.Mn₂O₃.H₂O, a basic lead manganite. W. SERGERBLOM

X-ray diffraction measurements upon the pyroxenes. R. W. G. WYCKOFF, H. E. MERWIN AND H. S. WASHINGTON. *Am. J. Sci.* **10**, 383-97(1925).—From an examn. of their X-ray powder diffraction photographs it is shown that with the exception of clinoenstatite, babingtonite, spodumene, pyroxmangite, alamosite and sobralite (each of which has a pattern unlike any other), all of the different kinds of minerals usually grouped among the pyroxenes have the structure of either diopside, enstatite, wollastonite or rhodonite. From measurements of several typical augites, which in structure are like diopside, it is seen that the excess Fe₂O₃ and Al₂O₃ have no clearly marked effect on the X-ray diffraction pattern. Density calcns., combined with the X-ray spacing measurements, prove that these oxides cannot be present in the mols. in addn. to the diopside-like constituent; they do not, however, distinguish between the possibility (1) of fine-grained admixt. of the oxides themselves or of some other ferric and Al compds., or (2) of some sort of at. replacement involving these oxides. Comparative spacing measurements of minerals of known chem. compn. show that in these pyroxenes Fe⁺ replaces Mg with practically no change in shape or size of the resulting crystal. Mn⁺ seems to have a slightly larger and Ca a much larger effective vol. than these 2 metals.

GEORGE L. CLARK

Constitution of glauconite and celadonite. L. L. FERMOR. *Records Geol. Survey India* **58**, 330-7(1925).—From a mean of 12 analyses of glauconite, F. obtains 2R₂O₃ · (R₂O, R₂O) · 8SiO₂ · 4½H₂O; and from 5 of celadonite R₂O · 4(R₂O₃, RO) · 10SiO₂ · 6H₂O. No new analyses are included. J. F. SCHAIRER

Xenotime from Ytterby. G. K. ALMSTROM. *Geol. För. Förh.* **47**, 290-8(1925).—The xenotime shows cleavage parallel to a tetragonal prism, is optically uniaxial, +. It is somewhat cracked with dark decompn. products on the broken surfaces. Analysis gave: P₂O₅ 33.14, Ta acids 0.18, SiO₂ 2.27, ThO₂ 0.12, CeO₂ 1.04, ZrO₂ 0.76, Ce earth oxides 3.79, Gd earth oxides, 49.45, Al₂O₃ 1.49, Fe₂O₃ 0.91, BeO 0.04, CaO 4.82, MgO 0.31, K₂O 0.09, Na₂O 0.10, H₂O 1.17, sum 99.68%. W. SERGERBLOM

A monazite-bearing pegmatite near Normanville. R. GRENFELL THOMAS. *Trans. Proc. Roy. Soc. S. Australia* **48**, 258-68(1924).—Lenses of rutile and monazite in com. amts. are present in the border phases of the pegmatite. The monazite is traversed by an irregular net work of hydrated oxides of rare earths. A fresh unaltered monazite gave: P₂O₅ 26.88, Ce₂O₃ 25.09, La₂O₃ etc. 24.32, ThO₂ 10.70, Y₂O₃ and Er₂O₃ 4.00, CaO 2.60, TiO₂ 1.70, SiO₂ 1.65, Fe₂O₃ 0.85, PbO 0.55, H₂O (at 110°) 0.40, H₂O and gases (above 110°) 1.52, sum 100.26%. The Pb-Th ratio gives an age of 1,073 million years. An analysis of biotite gave: SiO₂ 37.10, Al₂O₃ 13.60, Fe₂O₃ 4.47, FeO 7.63, TiO₂ (6.75% of included rutile) 7.00, MgO 16.60, CaO 1.00, Na₂O 1.78, K₂O 8.91, H₂O (at 110°) 0.10, H₂O (above 110°) 2.77, sum 101.26%. J. F. SCHAIRER

New researches on the autunite of Lurisia. C. PORLEZZA AND A. DONATI. *Ann. chim. applicata* **15**, 518-34(1925).—The autunite ore of Lurisia has already been studied by Lencio (C. A. **8**, 887) and by P. (*Ricerche relative all'autunite di Lurisia*, Pisa 1921). It is composed of S-yellow and greenish yellow crystals, the latter contg. twice the amt. of As as impurity as the former. Chem. and spectrographic analysis revealed the presence of Fe, U, Mn, Ca, K, Na, Sr, Al, Si, P, Mg, Ba, Zn, Cu, Pb and As, besides spectrum lines which could not be identified. The Ra content of 9 samples varied greatly, 1 g. of Ra being present per 200, 333, 1000, 2000, 1600, 5000 and 8000 tons of sample and 2 samples contg. none. This renders the mineral of potential value as a com. source of Ra. C. C. DAVIS

The correlative value of heavy minerals. F. G. TICKELL. *Bull. Am. Assoc. Petroleum Geol.* 8, 158-68 (1924).—Heavy minerals most common in California oil field sediments are: amphiboles, pyroxenes, opaque minerals such as magnetite, ilmenite, etc., epidote, micas, garnets, zircon, tourmaline and others. Data for the recognition of mineral grains with a polarizing microscope are given. C. I. C.

The possible role of transportation in metalliferous deposits. L. DELAUNAY. *Soc. Geol. Belg. Livre jubilaire 1874-1924*, 113-5 (1925).—Geological. L. W. RIGGS

Origin of primary ore deposits. R. C. WILSON. *Chem. Eng. Mining Rev.* 18, 51-4 (1925).—Early theories regarding the origin of ore deposits are reviewed. The downward changes of ore deposits with an ideal reconstructed vein system as proposed by Emmons (C. A. 19, 2009) are applied to the Au deposits of W. Australia. L. W. R.

Platinum in industry and commerce. II. Minerals and ores of platinum. III. Geological characteristics of platinum occurrences. N. K. VISOTSKII. *Matter on the natural productive forces of Russia* 4, 109-343 (1923); *Mineralog. Abstracts* 2, 540, of C. A. 18, 3340.—On Mt. Rudnaya is found a pyrrhotite deposit contg. 1.47% Cu and 1.05% Ni and some Pt, Pd and Au. The ore carries about 0.5% Pt. The auriferous quartz veins of the Urals, Fe ore of Nizhne-Tagil and Goroblagodat, cupriferous sandstones and phosphorite nodules in govt. Vyatka all carry some Pt. J. F. S.

Mineral production of India during 1924. L. L. FERMOR. *Records Geol. Survey India* 58, 241-322 (1925).—Increases over 1923 total production of the following are recorded: coal, petroleum, Mn ore, Au, Pb ore, Ag, building materials, mica, Fe ore. Sn ore, KNO_3 , Cu, Zn, clays, MgCO_3 , bauxite, monazite, gypsum, ocher, zircon, asbestos, amber, cyanite and Bi ore. Decreases are recorded for NaCl, jadeite, Cr ore, gems, W ore, apatite, talc, BaSO_4 , ilmenite, alum, fuller's earth, soda and hyalite. J. F. S.

Sulfur deposits of New Zealand. E. P. DOW. *Proc. Australasian Inst. Mining & Metallurgy* No. 58, 29-46 (1925).—Geology, origin, mode of occurrence and mining methods are discussed. The deposits are small and isolated. A. BUTTS

Geology of a part of western Texas and southeastern New Mexico with special reference to salt and potash. H. W. HOORS. U. S. Geol. Survey, *Bull.* 780B, 126 pp (1925).—A review of the search for potash in this region from 1911 to 1921 is given. The prospects for salt in Texas and New Mexico indicate many billions of tons located where solar evapn. may be used. While these deposits cannot compete at present with those of other states, they constitute an extensive reserve. Potash has been found in a number of wells drilled for petroleum, and in a few instances drilled for potash. More extensive drillings are necessary before the economic importance of these potash deposits can be estd. L. W. RIGGS

Geology and resources of the Gallup-zuni basin, New Mexico. J. D. SEARS. U. S. Geol. Survey, *Bull.* 767, 52 pp. (1925).—The coal of this district is a good grade of semibituminous, which compares well with competing coals. The av. B. t. u. of 27 samples was 11,110. The total production of the district to the end of 1923 was over 19 million tons, the output for 1923 being 821,415 tons. Among other economic resources of the Gallup-zuni basin are fire clay, sand, building stone, adobe, crushed rock and an adequate water supply. Prospecting for petroleum has so far been unsuccessful. L. W. RIGGS

Kerogen and its relation to the origin of oil. E. A. TRAGER. *Bull. Am. Assoc. Petroleum Geol.* 8, 301-11 (1924).—Kerogen is the org. matter insol. at low temps and pressures which yields petroleum by natural or artificial distn. Although similar in appearance to resin, it is not a resin because of this insoly. in org. solvents such as alc., ether and CCl_4 , and because of the difference in its end products when distd. by the usual methods of destructive distn. Kerogen is most probably an intermediate product between an org. source, i. e., plants and animals, and petroleum. The most favorable conditions for the deposition and accumulation of such original org. deriv. material is in swamps, bogs, lagoons and within the zone of shore-line deposition. Part of the kerogen which is found today was an end product of biochem. decompn. prior to consolidation and is indigenous to the beds which contain it. Other occurrences are secondary to deposition, probably derived from org. detritus. Kerogen, when first formed, prior to being subjected to high temps. or pressures, appears brownish to dark orange in color, and is optically inactive. Heating kerogen to a temp. slightly less than the temp. of vaporization and then allowing it to cool converts it into a vitreous, lemon-colored, anisotropic substance. Kerogen can be converted into oil either by the aid of heat or by pressure. In the latter case, the pressure must be of such a nature as to allow mol. displacement. C. I. C.

The relation of oil shale to petroleum. F. M. VAN TUYL AND C. O. BLACKBURN. *Bull. Am. Assoc. Petroleum Geol.* 9, 1127-42 (1925).—See C. A. 20, 497. C. I. C.

Geology and rocks in the vicinity of Bolivar, Venezuela. L. DUPARC AND L. CUISINIER. *Soc. Geol. Belg. Livre jubilaire 1874-1924*, 185-211(1925).—The lithological and optical characters of these granitic rocks are described at length, and 12 chem. analyses are reported. L. W. RIGGS

Diabase from Gevle. H. VON ECKERMANN. *Geol. För. Förh.* 47, 299-310(1925).—The mineral compn. is chiefly tabular crystals of feldspar iddingsite, delessite, ores, apatite, serpentine and partly decompd. glass. Its chem. compn. is: SiO_2 47.10, TiO_2 1.24, Al_2O_3 17.06, Fe_2O_3 6.64, FeO 9.47, MnO 0.25, CaO 7.06, MgO 1.10, K_2O 1.48, Na_2O 2.44, P_2O_5 0.82, CO_2 0.54, Cl 0.16, S trace, H_2O (+110°) 3.18, sum 100.54%; sp gr. 2.905. Comparative calcn. shows: iddingsite 6.66, feldspar 55.81, delessite 4.77, apatite 2.74, ores 15.74 and glass 14.82%. W. SEGERBLOM

Chemical composition of the red potassium leptytes in the zinc ore fields at Ämmeberg. G. T. LINDROTH. *Geol. För. Förh.* 47, 498-503(1925).—A new analysis by J. gives: SiO_2 63.27, TiO_2 0.10, Al_2O_3 15.94, Fe_2O_3 3.16, FeO 0.40, MnO 0.15, MgO 1.22, CaO 3.16, BaO not detd., Na_2O 3.96, K_2O 8.12, P_2O_5 0.06, S not detd., H_2O 0.31, sum 99.85%. These are compared with data previously found by L. Yngström; SiO_2 and K_2O are lower and Fe_2O_3 and CaO are higher. W. SEGERBLOM

The lavas of Fouqué Kameni, Santorin, Greece. A. LACROIX AND CONST. A. KTENAS. *Compt. rend.* 181, 893-5(1925).—Chem. analyses are reported of lavas from this volcano erupted in the years 46, 1869 and 1925; also of a sample of one of the islets which appeared during or after an eruption. L. W. RIGGS

The geology of the Rhobell Fawr district. A. K. WELLS. *Quart. J. Geol. Soc.* 81, 463-538(1925).—An analysis of a dacite, an average spilite and a variolite are included. J. F. SCHAIRER

Eruptive rocks of Camena, Roumania. D. M. CADERE. *Anuarul Inst. Geol. Romaniei* 10, 121-299(1925). (Résumé in French).—Chem. analyses, phys. consts. and various ratios for 25 samples of eruptive rocks are assembled in 8 tables. L. W. R.

Basaltic lavas penetrated by the deep boring for coal at Bhusawal, Bombay. L. L. FERMOR. *Records Geol. Survey India* 58, 93-240(1925).—Chabazite in the vesicles of the traps crystd. between 374° and 280°. An analysis of chlorophaeie is given and its identity with palagonite shown. J. F. SCHAIRER

Palagonite-bearing dolerite from Nagpur: nature and origin of palagonite. D. N. WADIN. *Records Geol. Survey India* 58, 338-43(1925).—Palagonite is not a definite mineral but an amorphous decompn. product of variable compn. formed *in situ* in the rock. It is not the product of alteration of interstitial glass alone, but has been formed by the decompn. of the ferromagnesian constituents of basic rocks. J. F. S.

Geology of the Milton district, N. S. Wales. IDA A. BROWN. *Proc. Linnean Soc. N. S. Wales* 50, 448-65(1925).—A geological and lithological study. Chem. analyses of rock specimens from this district and of similar rocks of European and American localities are quoted. L. W. RIGGS

Some occurrences of spherulitic siderite and other carbonates in sediments. EDMONDSON SPENCER. *Quart. J. Geol. Soc.* 81, 667-705(1925).—The spherulitic siderite was formed by the absorption of Fe carbonate, humate, or possibly colloidal hydrates by fine grained and partly colloidal sediments. Ten analyses are included. J. F. SCHAIRER

Glauconite and cretaceous formations traversed by the Harchies shafts, near Mons, Belgium. L. CAYEUX. *Soc. Geol. Belg. Livre jubilaire 1874-1924*, 65-82(1925).—These deposits are described from a lithologic point of view. The glauconite is probably of bacterial origin. L. W. RIGGS

The Sulphur salt dome, Louisiana. P. K. KELLEY. *Bull. Am. Assoc. Petroleum Geol.* 9, 479-98(1925).—The Sulphur salt dome is a typical Gulf Coast salt dome, but is exceptional in its small area, in the great thickness of the cap and in the richness of its deposit of native S. The cap is composed of anhydrite and a mantle-like mass of "lime" rock covering the top and flanks of the anhydrite. The S is found as a secondary mineral in the transition zone between the "lime" rock and the anhydrite and has probably been pptd. from H_2S or metallic sulfides in soln. After a long history of vain expensive attempts to mine the S, the Frasch process was perfected, by which the S is melted in place and pumped in liquid form to the surface. The total production to date has been about 9,000,000 tons of S with a gross value of \$150,000,000. Heavy oil was encountered in the early S wells, but not in com. quantity. The flanks have not been well tested for oil. C. L. C.

Big Hill salt dome, Matagorda County, Texas. A. G. WOLF. *Bull. Am. Assoc. Petroleum Geol.* 9, 711-37(1925).—Big Hill is a characteristic Gulf Coast salt dome and has a distinct salt-dome mound, a sub-circular salt core intruded into Tertiary sedi-

ments and a thick cap on the top of the salt. The cap contains an extensive and important deposit of S. The cap is composed of (a) a "barren" cap above, (b) the S-bearing zone composed chiefly of limestone and grading below into (c) a thick deposit of barren anhydrite. The S is secondary and later than the limestone and anhydrite. The S is mined by the Frasch process. A review is given of the possible reactions for the formation of the S. A small quantity of oil was produced in the early days, mostly from the top of the cap.

Origin of North American salt domes. E. DEGOLYER. *Bull. Am. Assoc. Petroleum Geol.* 9, 831-76(1925).—Exploration of the known domes for cap-rock pools and S deposits from 1901 to 1916-1918 gave more information on the salt, anhydrite, gypsum, limestone, S and various minor minerals—the salt dome materials—and theories of deposition from soln. became the vogue. The development of important oil deposits in the lateral sands flanking the salt masses, from 1912 to date, concd. attention on the structural features of the dome. The deposition-from-soln. and the lifting-power-of-crystn. theories seemed to be inadequate to explain the sharp and considerable uplift caused by the formation of the salt core and cap rock, and, with a growing recognition of the similarity of the American salt domes to the salt structures of Germany, Roumania, Mexico and elsewhere, came a gradual swing to the theory of tectonic origin. This theory supposes that the plastic salt was forced by pressure to flow from originally bedded deposits into its present position. D. accepts the tectonic or pressure-flowage theory for the origin of American salt domes, and believes that the most serious objection raised by its opponents—the lack of evidence as to the existence of sedimentary deposits—is no longer tenable in view of the recent discovery of potash salts and fossil algae in the salt core of the Markham dome.

The American salt dome problem in the light of the Roumanian and German salt domes. D. C. BARTON. *Bull. Am. Assoc. Petroleum Geol.* 9, 1227-68(1925).—The American salt-dome problems are divisible into 2 parallel series, one comprising problems of description, the other problems of theory. The soln. of the latter is of necessity dependent upon the soln. of the former. The American salt domes consist of subcircular stocklike masses of salt, capped in most cases by limestone and gypsum-anhydrite intruded into and surrounded by sediments which dip quaquaversally away from the salt core. The domes show certain alignment. They occur in regions of geologic quiescence where there has been no compressive folding. In Roumania, the Carpathian-Subcarpathian domes consist of narrow, elongated, vertical intrusions of the Saliere salt, clays and marls along anticlinal axes and into a thick series of sediments. The domes are aligned along structural, mostly anticlinal, axes which reflect the effect of the Carpathian tectonics. Their origin has usually been attributed to tangential or tectonic thrust. The transylvanian domes are aligned on anticlinal axes which are sub-parallel to the periphery of the basin. The German salt domes are a phase of the K salt deposits in which the structural deformation has been worked out in detail. There is a complete gradation from undeformed sedimentary beds through broad anticlines with slightly swollen cores of salt (Stassfurt type), sharp anticlines where the salt core is starting to pierce the cover (Asse type), to broken anticlines in which the salt core has been squeezed up between the two flanks (Leine type), or to salt stocks (Hannovian type) in which a plug-like mass of salt has been intruded for thousands of meters vertically into the overlying sediments. The salt domes and ridges are aligned along anticlinal axes. Many of the domes seem to be at the intersection of axes. The upthrust of the salt cores is attributed to tectonic or isostatic upthrust. In view of the evidence of the Roumanian and German salt domes, in addition to what is known about the American domes, it would seem unreasonable to believe that the American salt domes are not the result of the plastic deformation and upthrust of a sedimentary salt series.

Caliche and pseudo-anticlines. W. A. PRICE. *Bull. Am. Assoc. Petroleum Geol.* 9, 1009-17(1925).—Observations in central Tamaulipas, Mexico, indicate that pseudo-anticlines may be formed by the deposition of caliche (CaCO_3) at shallow depths below the surface. The surface rocks are accordingly disturbed, and dips up to 17° have been observed on strata which are apparently in place. The max. vertical uplift of these caliche-formed pseudo-anticlines is about 15 feet; their length along the axis of the "buckle" may be as much as 2000 feet. Beneath the pseudo-anticline the strata are essentially horizontal. Caliche deposition is seen to be a factor in the process of weathering in semiarid regions; on the one hand, it moves and disrupts the rock beds and aids in the penetration of plant roots at the outcrop; on the other hand, it retards weathering and erosion by recementing the rock fragments.

Water analyses in oil production and some analyses from Poison Spider, Wyoming.

E. M. PARKS. *Bull. Am. Assoc. Petroleum Geol.* 9, 927-46(1925).—The use of analyses in detg. the source of oil-field waters is urged. The meaning of analyses and the different methods of graphic statement are illustrated. A new form of graph believed to be clearer and simpler to use is suggested. As an example of the use of water analysis, 19 analyses from the Tensleep, Dakota, Morrison and Sundance sands of South Casper Creek, Poison Spider and Notches, Wyoming, are tabulated and studied graphically, the conclusion being that the waters are distinguishable from the analyses. The geochem. relations between the oil and water are briefly reviewed. C. L. C.

Analyses of Wyoming oil-field waters. E. L. ESTABROOK. *Bull. Am. Assoc. Petroleum Geol.* 9, 235-46(1925).—In general, waters in Wyoming oil fields show a tendency toward a reduction in sulfate content and increase in carbonate and Cl content and general concn. with increasing depths unless the waters have been modified by circulation. Secondary salinity decreases with depth, and in cases of deeper sands disappears altogether. The Dakota sand waters show a content of sulfate at greater depths than the Frontier sand waters, on account of more rapid water circulation and general replenishment of sulfates to the deeper waters. In Wyoming fields, waters in contact with oils show a tendency toward the reduction of sulfates and increase in carbonates. Oils in contact with underground waters are altered and show a reduction in lighter fractions which results in lower gravity oil. The Salt Creek field shows alteration of the oil in a zone extending from 100 to 150 feet above the water line. In the Big Muddy field, the oil appears to be altered over the entire producing area, probably because of rapid water circulation which is shown by the high sulfate content of the water, tilted water table, and nearness of outcrops. C. L. C.

Calcium chloride waters from certain oil fields in Ventura County, California. F. S. HUDSON AND N. L. TALIAFERRO. *Bull. Am. Assoc. Petroleum Geol.* 9, 1071-88(1925).—While engaged in a detailed study of the South Mountain and Shiel's Canyon oil fields it was found that the chem. compn. of the underground waters differs considerably from that of the usual Calif. oil-field brines, in that CaCl_2 instead of NaCl is the chief constituent. The fact that this difference in compn. persists in the fields along the south side of the Santa Clara River indicates that these underground waters had a different origin or subsequent history from the waters in other fields, both in Ventura County and other parts of the state. Although CaCl_2 waters occur in other parts of the world, they are far from common and, therefore, seem to owe their origin to certain special conditions. H. and T. suggest their probable origin. C. L. C.

Probable origin of thermal waters of Aix-les-Bains, Savoy, and the role of the tectonic accidents in the thermalization and mineralization of the springs. W. KILIAN. *Soc. Geol. Belg. Livre jubilaire 1874-1924*, 97-102(1925).—A geological study.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, ROBERT S. WILLIAMS

The metal industry and its technical and scientific development in recent years. J. CZOCHRALSKI. *Z. Metallkunde* 18, 1-6, 43-50(1926). E. H.

A new regenerative muffle. ANON. *Metal Ind.* (London) 27, 74-5(1925). A muffle annealing furnace of regenerative type is described for which the combination of relative fuel efficiency of open-flame annealing with freedom from staining and over-heating of pot-annealing is claimed. Special methods for obtaining max. heat efficiency are mentioned. W. H. BOYNTON

The production and the available supplies of iron ore in Sweden. WALTER PERTERSSON. *Jernkontorets Annaler* 109, Supplementary issue, 7-18(1925).

The consumption of power in the Swedish iron industry and the prospects of development of the industry. TORSTEN HOLMGREN. *Jernkontorets Annaler* 109, Supplementary issue, 19-99(1925). C. A. ROBAK

Thermal regulation of a cupola furnace. E. PIWOWARSKY AND F. MEYER. *Stahl u. Eisen* 45, 1017-22(1925).—Systematic investigations were made on the thermal efficiency of an ordinary cupola with fore-hearth, in which the ratio of the total cross section of the tuyères to that of the smelting zone was 0.28. The temp. in the cupola at 5 points, the compn. of the waste gases and of the Fe and slag, and the heat balance were detd., both with const. coke charge and varying blast, and with const. blast but varying charges of coke. In the first case the output of Fe and the temps. of the Fe and slag fell as the quantity of air decreased, but the products of combustion and the thermal efficiency were little affected. In the second case increasing the quantity of coke charged diminished the output of Fe, the proportion of CO₂ to CO in the waste gases, and also the thermal efficiency, but the temps. of the Fe and slag rose. Excess of coke was more disadvantageous than a moderate deficiency or small excess of air. Diminution of the coke charged did not increase the waste of Fe if the proportion of charge coke did not fall below 7.5%. No connection was found between the mech. properties of the Fe and the quantity of charge coke or air blast used. B. C. A.

Blowing in, damping and blowing out blast furnaces. H. VON SCHWARZE. *Stahl u. Eisen* 45, 609-14(1925).—Newly built blast furnaces are generally dried by an air blast at 100° instead of by burning wood on the hearth. Furnaces are usually damped by charging a damping mixt. with lessened ore and increased coke content and contg. 5% of lime. The fire is put out as quickly as possible by quenching with water and the charge is afterwards dried in the furnace with a current of air. A new method of damping down by choking the furnace with gas is described. Pyrophoric C, produced by decompn. of the gas, was deposited in the furnace shaft where the brickwork was thin, and on access of air was rapidly oxidized, with such intense local heating that the deposits had to be quenched with water. The use of covering plates is being abandoned. As material for mending brickwork cracks, 3 parts by vol. of loam sand to 1 part of cement was used. Not many furnaces were scraped out after shutting down. Different methods of blowing in damped furnaces are described. The coke may be brought to ignition in the hearth by means of O, air, or petroleum. The hearth jacket must be carefully watched during damping, as cracks are liable to occur after shutting down and the quenching water should be allowed to stand in the hearth jacket as long as possible. Experience with furnaces melting special charges is given. In blowing out use was made of limestone, wet blast-furnace slag or ore. The temp. of the waste gases must be carefully watched to prevent damage to the filter-bags. B. C. A.

Production of cyanide in the blast-furnace process. H. BRAUNE. *Stahl u. Eisen* 45, 581-2(1925).—Swedish blast furnaces making Lancashire Fe and charged with a high proportion of ore yielded Fe of good quality at a slow rate of working, but above a certain rate of production the Fe became brittle and unsatisfactory. With slow working the reduction of the ore was completed above the tuyères, but at the faster rate the unreduced Fe compds. acted as catalysts in the formation of cyanides, which accounted for the brittleness of the Fe. The N content was 0.02%, compared with 0.003-0.005%.

in the former case. This formation of cyanide limits the size and rate of working of the Swedish charcoal blast furnace. An attempt to use the blast-furnace process for the production of KCN with grey Fe as a by-product was unsuccessful, as the unreduced Fe compds. did not come into the neighborhood of the tuyères. Similar catalytic formation of cyanides occurs in the converter process, *e. g.*, in underblown metal and in the open-hearth process if the slag is not carefully skimmed. B. C. A.

Scrap in blast-furnace burdens. F. BORMANN. *Stahl u. Eisen* 45, 2041-9, 2085-91 (1925); *Iron Age* 117, 481-2 (1926).—During the World War it became necessary to utilize scrap in blast furnace charges. Coke consumption is lowered about 30% and the output is increased about 60% by its use. The greater fuel value of the waste gases and the resulting larger excess of energy available are advantages. Disadvantages of using scrap include: the difficulty of loading and handling the scrap, greater loss of heat and use of cooling water, and changes in the compn. of the pig iron due to non-uniform scrap, and a lower total C in the pig iron. W. H. BOYNTON

The carbon-scrap process. G. L. SACHAROV. *Trans. Inst. Econ. Mineralogy and Petrography* (Russia) 1924, No. II, 1-53.—For the C-scrap process of steel making there are given the properties of carbonizers, the time period of charging the furnace, the duration of the smelting, the peculiarities accompanying the smelting, the bubbling period, conditions of removing the S from the Martin bath, deoxidation of steel, the character of the Mert system, and examples of charges. A good English summary is given at the end of the article. J. S. JOFFE

Desulfurization, degasification and deoxidation processes for high-grade cast iron. J. MEIJTENS. *Stahl u. Eisen* 45, 449-57 (1925), cf. C. A. 16, 2833.—The influence of limestone, fluorspar and increased Mn content as desulfurizing reagents is described. The expts. of Walter showed that salts of alkali and alk. earth metals have a favorable desulfurizing influence whether the Mn content is high or low and they could be applied without affecting the Si and C present. If such addns. are made to the ladle there is a difficulty in removing the slag, and different ladle designs for overcoming this difficulty are described. A later method involved the use of an Fe receiver, which was filled with slag-free Fe to which the desulfurizing addns. were made. Desulfurization was accompanied by degasification and deoxidation and it was found that low-S Fe could be made with a large amt. of scrap cast Fe in the charge. In later developments of the process a fixed forehearth (Rein-Durkopp) is used instead of a movable Fe receiver and a special overflow device (Luyken) to seal the forehearth from the furnace. Particulars of the upkeep and working of a desulfurizing installation are given and a table showing the mech. properties of cast irons before and after desulfurization. The decrease in S content amounts to 50-60%. Only a small increase in tensile and bending strength is shown, and a slight decrease in hardness, but the desulfurized Fe is more easily machined. Photomicrographs show no differences in structure of the Fe before and after desulfurization. The low-S Fe is suitable for castings sensitive to shrinkage strains, and the castings show greater resistance to wear. The desulfurized Fe has a diminished gas content. B. C. A.

Smelting secondary aluminum and aluminum alloys. III. Constitution and evaluation of high aluminum scraps. R. J. ANDERSON. *Metal Ind.* (N. Y.); 24, 63-5 (1926); cf. C. A. 19, 810. W. H. BOYNTON

Steel molding sands and their behavior under high temperature. A. L. CURTIS. *Engineering* 121, 216-8, 248-9 (1926).—See C. A. 19, 3466. E. H.

Converter for the calcination of low-grade calamines. E. F. PASELLA. *Rass. min. met. chim.* 64, 12-3 (1926).—A new type of converter is described, which is especially adapted to the calcination of low-grade Zn ores or ores in which Zn is only an accessory metal. The process is also applicable to the calcination of carbonates such as Fe carbonate, limestone and those used in cement manuf. For these purposes it is more economical than the Oxland or reverberatory type of furnace in that charcoal is intimately mixed with the ore and an agglomerated, more easily transportable product is obtained. The furnace is a bottomless truncated cone with steel walls 10 mm. thick, of 1.2 m. internal diam. at the top (orifice), 0.8 m. diam. at the bottom and 0.9 m. high. Much larger furnaces are, however, practicable. The base or grate is a movable steel plate with holes 4 mm. in diam. An artificial draft enters from below. The app. is pivoted so that when charged it is in unstable equil. and so can be easily tipped and discharged. It is charged at the top with a mixt. of finely divided ore and powdered wood charcoal (4-5% by wt. of the ore). Intimate mixing is indispensable. Coal or coke tends to form agglomerates, with unequal calcination. The grate is first covered with charcoal, the latter is ignited, the mixt. of ore and charcoal is added, the draft is turned on, the ore-charcoal mixt. is added progressively as combustion proceeds until the furnace

is full, at which time the operation is usually complete. A 3-h.-p. fan (supplying air at a pressure of 8–20 cm. of H_2O) is sufficient for 4 furnaces. Four hrs. are usually required to calcine 1200–1300 kg. of calamine.

C. C. DAVIS

Chemical stability of a number of metals and alloys, especially of those containing molybdenum. W. GUERTLER AND T. LIEPUS. *Z. Metallkunde* 17, 310–5(1925).—This is a preliminary investigation of the corrosion of heavy metals and their alloys by the common reagents (acids, bases, CO_2 + air, sea water, etc.). The results of the corrosion were noted after $\frac{1}{10}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, 2, 4, 8, 16, 24 and 48 hrs. It was found that it is most difficult to obtain acid-proof alloys. A few quaternary alloys contg. Ni, Cr, Co and Mo and a ternary Ni-Cr-Mo alloy with 0.62% C resisted the action of HNO_3 fairly well, while a ternary Ni-Si-Mo alloy (90:3:7), a ternary Ni-Co-Mo alloy (10:31:56) and a ternary Co-Mn-Mo alloy (40:50:10) resisted the action of dilute HCl. A large number of alloys withstood the action of sea water quite well. The combined action of sea water and air was, however, not studied.

H. S. VAN KLOOSTER

Representation of recrystallization phenomena on the basis of grain growth by hot-work deformation. H. HANEMANN. *Z. Metallkunde* 17, 316–9(1925).—H. studied the grain growth of pure Cu at const. temp. (300°, 400°, 500°, 700° and 900°) as a function of the percentage deformation. The metal was elongated while hot and kept at const. temp. until the recrystn. was complete. It was then cooled and the grain size measured. The data obtained were plotted in a 3-dimensional diagram, the grain size vertically, and temp. of hot-work and percentage deformation at right angles in a horizontal plane. For small deformation no recrystn. took place. The max. amt. of deformation without recrystn. is the greater, the lower the temp. of hot-work. As soon as this limit is exceeded large values for the grain size are recorded. For still greater deformation H. finds that the grain sizes as a function of hot-work lie on hyperbolic curves. The curve representing the recrystn. as a function of the temp. is also hyperbolic and shows that the limit below which Cu cannot be recrystd. lies slightly above 200°. A number of conclusions are drawn from the diagram.

H. S. V. K.

Microscope and ultra-violet light. F. F. LUCAS. *Iron Age* 117, 555–7(1926).—The app. used for making photomicrographs by ultra-violet light is described and illustrated. The image of the specimen must be viewed and focused by means of a fluorescent screen. A Hg-vapor lamp is used for preliminary observation. A line from the Cd or Mg spectrum is used as the source of ultra-violet rays. Great exactness of focus is required but is difficult to attain. Failure to secure crit. illumination is also a frequent cause of poor results. Ultra-violet light has selective properties and is not absorbed in the same way as ordinary light by the steel constituents. Martensite needles may photograph either light or dark by ultra-violet light, and pearlite reflects it. The ultra-violet equipment is capable of giving superior results and of doubling the resolving power of the apochromatic system. (Note by abstractor: The results shown by the author, however, do not appear to be any better than those he has previously obtained with standard equipment.)

G. F. C.

Some attempts to measure the drawing properties of metals. WM. S. MONTGOMERY, JR. AND E. R. JENDERS. *J. Mech. Eng.* 48, 119–24(1926).—Samples of sheet-metal for drawing were tested by the scleroscope, Rockwell, Herbert pendulum, Erichsen, and metallographic methods, and the results were correlated with the actual drawing qualities as observed in manuf. A detailed discussion is given of 3 diff. ways of using the Herbert pendulum, which failed to give satisfactory evidence for judging drawing quality. The Erichsen test and photomicrographs were most reliable. Tests of indentation hardness both before and after deformation might be a good method.

G. F. C.

The tensile properties of metals at high temperatures. T. D. LYNCH, N. L. MOCHEL AND P. G. McVETRY. *Proc. Am. Soc. Testing Materials* 25, Pt. II, 5–26(1925).—The detn. of safe working stresses under high temp. conditions required long-time tests. Medium-C steel, 5% Ni steel, stainless Fe and cast Mn bronze were tested in tension at temps. up to 500°. The app. used for short and for long-time tests are described and illustrated. Stress-strain curves are shown, and the variations of the tensile properties with temp. are plotted. The short-time tests gave the following results: the elastic properties of the medium-C steel decreased with increasing temp., the ductility decreased to about 250° and then increased, and the tensile strength showed a min. at 100° and a max. at 275°; the Ni steel showed about the same results, with better ductility; the stainless Fe showed much less effect of temp. increase; the Mn bronze showed no change in elastic properties up to 260°, but a drop in tensile strength. The elongations of medium-C steel at 400° under stresses of 25,000 and 14,000 lb. per sq. in., resp., are plotted against time. Previous heat-treatment caused a lower final rate of extension. A

stress slightly lower than the proportional limit at a given temp. can be carried by medium-C steel indefinitely without continued extension. Mn bronze elongated more than steel in these long-time tests and showed no tendency to stop stretching at a stress 10% below the proportional limit at 260°. At a const. high temp. the stress varied linearly with the logarithm of the time to cause fracture. Medium-C steel stressed above the proportional limit for over 200 hrs. at 400°, and then tested at normal temp. showed decreased ductility, increased strength and elastic properties except the modulus which was not changed. The results were similar to those from cold-working and tempering and will be investigated further. G. F. C.

Fatigue of metals by direct stress. P. I. IRWIN. *Proc. Am. Soc. Testing Materials* 25, Pt. II, 53-65(1925).—Various objections to the bending type of fatigue test were overcome by using a magnetic machine producing direct tensile and compressive stresses alternating at 2000 cycles per min. with specimens carefully prepd. and held in ball-and-socket alignment seats specially designed to prevent bending stress, vibration, and non-axial loading. Extremely regular stress-cycle curves were obtained. The machine was calibrated by means of a standard bar, the strains being measured with a delicate optical app. Comparative results on four steels and Mn bronze showed that the endurance limit obtained by direct stress was the same as that obtained by flexural stress. In discussion, H. F. Moore stated that allowance should be made in practice for the failure to secure exact axial loading in most cases. G. F. C.

Some fatigue tests on non-ferrous metals. R. R. MOORE. *Proc. Am. Soc. Testing Materials* 25, Pt. II, 66-96(1925); cf. C. A. 19, 2629.—In the discussion McAdam claims that all non-ferrous metals show an endurance limit at from one to 100 million cycles, and that stress-cycle semi-logarithmic graphs that show no curvature are abnormal. "The endurance ratio does not decrease with cold working until the boundary between moderate and severe cold working has been passed." The variation of endurance limit with chem. compn. is shown by curves for alloys of Cu with Sn, Zn, Al and Ni. Moore questions the strength of McAdam's evidence for the existence of an endurance limit for Ni, Monel metal, and some other alloys, and claims that 600 million cycles are not too many for worth-while results. Templin quotes results showing that duralumin after testing at 8000 lbs. per sq. in. for two billion cycles was not impaired in tensile strength, proportional limit or elongation. G. F. C.

Typical static and fatigue tests on steel at elevated temperature. T. McLEAN JASPER. *Proc. Am. Soc. Testing Materials* 25, Pt. II, 27-52(1925); cf. C. A. 19, 2629.—In discussion, J. K. Wood explained the changes in properties of steel at high temp. by changes in the viscosity of the plastic or amorphous phase. H. J. French questioned Jasper's claim that working steel at a blue heat gave the best strengthening effect. The life of metal at high temp. is reduced more by sustained loading than by alternating stress, on account of flow or creep. Data on flow of 0.24% C steel at different temps. and stresses are presented by charts. The stress-strain relations at high temps. should receive more attention. V. T. Malcolm gave the results of long-time tensile tests of cast C and Cr-Ni steel and described the app. used. At 540° the latter will endure 11,000 lbs. per sq. in. for long periods without deformation. T. D. Lynch, N. L. Mochel and P. J. McVetty questioned Jasper's claim that little or no advantage is gained by heat-treating a steel to be used above the bluing temp., and suggested that it should read "above the drawing temp. given the steel." Jasper replied that stressing above the bluing temp. seemed to have about the same effect on steel as annealing. Short-time tests should be correlated with the very long-time tests so that the time required by the latter may be saved. In some instances the difference in results may be only a small percentage. G. F. C.

Fatigue failures in steel. F. W. ROWE. *Metal Ind.* (London) 28, 133-5(1926).—In 85% of all cases the endurance limit of steel is between 40 and 55% of its tensile strength. The endurance limit cannot be correlated with other properties. Sharp notches often cause failure irrespective of quality of metal. The addn. of metal to a machine part may weaken it if abrupt changes in section are produced thereby. Roughening of the surface reduces the fatigue range. G. F. C.

A process for the prevention of embrittlement in malleable cast iron. L. H. MARSHALL. *Trans. Am. Inst. Min. & Met. Eng.* Feb., 1926, 8 pp.(advance copy); *Iron Age* 117, 558-60(1926); cf. C. A. 19, 1679.—Normal malleable castings often become brittle after hot-dip galvanizing. The brittleness is caused, not by the preliminary pickling nor by the Zn but by heating to the galvanizing temp., 460° and rapid cooling. Quenching from 600° to 800° improved the impact value, while quenching from 300° to 550° spoiled it. By quenching from 650° before galvanizing, the galvanized malleable castings were prevented from becoming brittle at normal or abnormally low temp.

(-30°), at which even plain malleable castings become brittle. The app. used in the com. application of this process is described. G. F. C.

A study of the shrinkage process in white and gray cast iron. PETER BARDENHEUER AND CARL FBBEFELD. *Mitt. K.-W. Inst. Eisenforsch.* **6**, 45-60(1925); *Stahl u. Eisen* **45**, 825-34, 1022 7.—In continuation of the investigation by Wüst and Schitzkowski (*Mitt. K.-W. Inst. Eisenforsch.* **4**, 105-24(1923)) concerning the effect of foreign material on the shrinkage of iron, the authors have studied the process of shrinking in white and gray cast iron. The change in length of a test bar cast in a sand mold was measured by the automatically registered displacement of two cross wires, 8-10 mm. in diameter passing through the ends of the bar and held in a suitable frame. On plotting the shrinkage in percent against the time curves are obtained which show that there is an initial expansion during the eutectic solidification which must be ascribed to a sudden decrease in the gas solubility during solidification. Experiments on bars of Swedish pig iron showed a smaller expansion *in vacuo* than in air. Pig iron rich in Mn did not expand on solidifying *in vacuo*. There is a normal shrinkage down to where the solid solution changes to pearlite (pre-pearlitic shrinkage) when a retardation in shrinkage or even a slight expansion is noticed and thence another normal shrinkage (post-pearlitic shrinkage). The difference in total shrinkage (=sum of pre- and post-pearlitic shrinkage) for white cast iron (about 1.88%) and gray cast iron (av. 1.24%) is mainly due to the difference in pre-pearlitic shrinkage, the post-pearlitic shrinkage being practically the same for both. The authors have found that the pre-pearlitic shrinkage can be reduced at will (even down to zero) by raising the temperature of the sand mold, thereby reducing the rate of cooling, decreasing the hardness and increasing the quantity of separated graphite (flakes become thicker). An example is given where the cracking of a cast iron frame having a heavy cross beam was avoided by preheating the sand mold to 500° . Curves and tables are given demonstrating the effects of Si, Mn, P and S on the shrinkage of gray cast iron. Elements which favor the separation of secondary graphite, like Si, decrease, and those that hamper the graphite separation (Mn, S) increase the shrinkage. Phosphorus, up to 3% has little or no effect on the shrinkage.

H. S. VAN KLOOSTER
Phenomena of graphite formation in gray pig iron. E. PIWOWARSKY. *Stahl u. Eisen* **45**, 457-8(1925).—A peculiar fracture was observed in cast-iron rods of 20 mm diam. (total C 3.2%, graphite 3.15%, Si 3.1%) made from Swedish charcoal pig iron and cast at a low temp. (1250°) in dry sand molds. The fracture consisted of a bright outer zone and core with a dark intermediate annulus, the only constituents present being graphite and ferrite. The differences in color are attributed to the type of graphite formation. In the bright zones the graphite occurred as small nodules, crystg. directly from the molten metal. The sand mold was coated with graphite, which probably acted as nuclei for the formation of graphite in the Fe. The middle zone was subjected to undercooling and the crystn. velocity was greater, whereby the size of the graphite lamellae increased. The core was not undercooled and in addn. was subjected to tensile stresses set up by the solidified outer zone. Similar observations were made on a cast iron contg. total C 3.65%, graphite 3.49%, Si 2.86%, cast from a temp. only 75-100 above melting point. The middle zone contained some combined C and the structure showed that the graphite formation proceeded from well-marked centers with considerable velocity. B. C. V.

Dilatometric investigation of the A_3 and A_4 transformations in pure iron. SEI KICHI SATO. *Sci. Repts. Tohoku Imp. Univ.* **14**, 513-27(1925).—The question as to whether Fe will expand or contract at the A_4 transformation was investigated by means of a differential dilatometric couple of Fe and Co, heated in a C-ring elec. furnace. The difference in elongation between the 2 parts of the couple was measured by a mirror system. Electrolytic Fe contg. only 0.006% C and 0.006% S was used. Contraction on heating through the A_3 point was observed, and abnormal expansion at the A_4 point, equal to about $\frac{3}{10}$ the contraction at A_3 . The results are shown by tables and diagrams, where the thermal dilatation curve of delta-Fe appears to form a continuation of that of alpha-Fe. The lattice parameters of alpha and gamma Fe as detd. by X ray analysis are quoted in confirmation of the dilatometer measurements. G. F. C.

The determination of the heat of precipitation of cementite from alpha and beta martensites. MASUO KAWAKAMI. *Sci. Repts. Tohoku Imp. Univ.* **14**, 559-68(1925).—Since by dilatometric investigation of a slowly heated quenched steel contractions at 170° and 340° are observed, cementite must ppt. more easily from one kind of martensite than from another. The former is called alpha, and the latter beta martensite. Yamada has measured the total heat of pptn. of cementite from both kinds. With about the same calorimeter, but with a nitrate mixt. fusing at 180° as the thermostat liquid,

tests were made with quenched and with tempered specimens of the same steels. From plotted temp. observations the difference due to cementite pptn. from alpha martensite was detd. That only alpha and not beta martensite decomposed in these tests was checked by dilatometric examn. The method used is described in detail. Alpha and beta martensites are definite phases, although not quite stable. The heat of pptn. of cementite from alpha martensite increases proportionately to the C content, like that from alpha plus beta martensite. In eutectoid steel the former is 3.7 cal. per g; Yamada's value of 6.57 cal. for the latter is approx. confirmed. G. F. C.

The solidus line in the iron-carbon system. SEIJI KAWA. *Sci. Repts. Tohoku Imp. Univ.* **14**, 529-36(1925).—The Fe-C solidus line was detd. by the elec. resistance method, in a C-ring elec. furnace with coal-gas atm. The resistances of specimens 0.5 cm. in diam. were measured over lengths of 5 cm. The expts. were made during heating at a rate of 150° per hr. and results from decarburized specimens were rejected. The soly. line of cementite into austenite was detd. by the same method in a nichrome furnace, during cooling after heating to complete soln. of the carbide. The results are tabulated and plotted on charts. The solidus line was found between that of Carpenter and Keeling and that of Gustowsky. G. F. C.

The rapid determination of structural or constitutional analysis. J. E. FLETCHER AND J. G. PEARCE. *Bull. Brit. Cast Iron Research Inst.* No. **11**, 17-20(1926).—A simple method for computing the structural compn. of cast Fe by wt from the chem. analysis is described and illustrated. The method involves the use of graphs, which are given. The phosphide eutectic contains 6.9% P and 1.9% C. Pearlite contains 13.5% Mn and Fe carbides. The microscope reveals the structural compn. by vol. G. F. C.

The limit of malleability of steel in the hot state as a function of its carbon content. E. COTEL. *Rev. universelle mines* [7], **9**, 27-9(1926).—The limiting % of C in steel which is malleable when hot has not been definitely established and moreover this value is different for rolling and for forging. It is probable that this limit for rolling is 0.95-1.0% C, i. e., when the structure is pearlitic alone. When hot the malleability of steels with C above 1% is very low and at 1.7% C it becomes inappreciable. A diagram with the % C abscissa and the temp. as ordinate is developed to show the field of practical malleability. The extreme limit for forging corresponds to 1.3% C or at the very most to 1.4%. Consequently Fe-C alloys from 1.3 to 1.4% C to 2.2% are neither steels nor cast Fe, but rather metals which are to be regarded as semi-steels. C. C. DAVIS

Study of the fragility of cold-rolled steel. GEORGES DELBART. *Compt. rend.* **182**, 131-3(1926); cf. *C. A.* **19**, 2015, 3244.—The resistance to shock, by the pendulum method, of notched bars of cold-rolled and annealed steels is given. Four steels are considered, analyzing C 0.115-0.48, Si 0.056-0.178, S 0.020-0.027, P 0.020-0.034 and Mn 0.50-0.78%. Annealing is done at successive 100° intervals up to 1000° and values for resistances at the various temps. are given. In the steels annealed below 700°, coarsened cementite is present; between 700° and 850° a mixt. of sorbite and globular pearlite is evident; and above 850° only sorbitic pearlite obtains. A max. of resistance results by rolling and annealing quickly to 700°. P. B. PLACE

Effect of the range of working temperature on the selection of steels for airplane motor valves. CHARLES GRARD. *Compt. rend.* **181**, 1143-5(1925).—On "forcing" the motor the exhaust valves are heated to about 900°, but the power developed per l. of gasoline is increased, with possibility of reducing the wt. of the engine per h. p. The valve-metal working under these conditions should be reversible (no transformation point in the range of working temps.), light, resistant to corrosion by the exhaust gases, and have a high resistance to shock and sufficient resiliency and hardness. G. found the most satisfactory steel to be one with C 0.4, Si 2.5 Cr 12%, which, after air-hardening at 1200° and tempering at 900°, had the following properties: Ac over 900°; d. 7.8; tensile strength (cold) \leq 92 kg./mm.²; elongation (cold) \leq 12%; resiliency (cold) \leq 4; Brinell hardness, cold 280, at 900° slightly less than 40 (slightly increased by addn. of 1.5% W). Valves made from this metal mounted on a 450-h. p. Lorraine motor stood at 50-hrs. endurance test and at the end had the same polish and texture as before the test. A. PAPINEAU-COUTURE

The behavior under stress of the iron crystals in steel. I and II. H. H. LESTER AND R. H. ABORN. *Army Ordnance* **6**, 120-7, 200-7(1925).—Information was sought regarding the stress and strain values in the crystals of steel under tension below and above the yield point and the effect of C content and heat treatment on those values. The conclusions were that individual crystals do not indicate the values of any of the elastic properties of the aggregate on account of irregularities in the elastic region due to strain recoveries and stepped slip; the individual Fe crystals take up the elastic loads

and may be under less stress and strain after plastic deformation, when the stress is carried in part by disorganized, imperfectly elastic material due to block slip; sorbite contains C in soln. in α Fe as a mol. dispersion of Fe carbide, causing distortion of the crystals, and increased slip resistance; sorbite also has a low crystal modulus and, therefore, less susceptibility to cracking. "Steel owes its strength to the nature of the bonding, the mutual interference between adjacent crystals, the effect of distorted crystal planes due to dissolved carbide, the effect of disorganized material formed during plastic deformation, and other effects." The proportional limit is the stress at which stepped slip begins to merge into block slip, while at the yield point block slip is predominant. The materials used were blued shim stock 0.003 in. thick, of 1.13% C annealed shim stock of 1.03% C; and steel ribbon of 0.15% C. The methods used for obtaining stress-strain curves are described. The theory and practice of X-ray test as applied in this work are discussed in detail. X-ray spectra of stressed and unstressed specimens of the same material were obtained at the same time on adjacent films. The delicate app. for stressing these specimens is described and illustrated. The spacings of the spectra lines on the films were measured repeatedly at different times to insure accuracy. Part II gives the results of tests and measurements in tables and diagrams.

G. F. C.

Effect of temperature on the behavior of iron and steel in the notched-bar impact test. R. H. GREAVES AND J. A. JONES. *J. Iron. Steel Inst.* (advance proof), Sept. 1925, 40 pp.; cf. *C. A.* 20, 567. G and J. studied the effect of temp. on the behavior of Swedish bar Fe, Armeo Fe, straight steels (0.13–0.52% C) and alloy steels (Ni-, Ni-Cr-, Ni-Cr-Mo-, and Cr-V-steels) in the notched-bar impact test. They also investigated the influence of the forms of the test pieces on the impact figures and compared the results of impact and of slow-bending tests. Load-extension expts. were performed at different temps., showing the effect of the rate of straining. The main results are represented in a number of diagrams. The general character of the impact figure-temp. curves is the same for all materials: a first max. occurs at temps. between -20° and 250° depending on the kind of ferrous alloy, the form of the test piece and of the notch, and the amt. of previous cold work. This max. is followed by a min. between 500° for Armeo Fe and 650° for some heat-treated alloy steels. Finally a second max. appears between 650° and 800° . For pure Fe this second max. is much lower than the first but medium-C steels and alloy steels give exceedingly high impact figures in this range.

H. S. VAN KLOOSTER

The Widmannstätten structure in iron-carbon and iron-nickel alloys and in meteorites. TUTO M KASÉ. *Sci. Repts. Tohoku Imp. Univ.* 14, 537–58 (1925).—The conclusions of others as to the origin of Widmannstätten structure are briefly reviewed. K. investigated its production in steel and its origin in meteorites. Steel showed this structure when heated above 1000° and cooled in air but not when quenched or slowly cooled. The Osmond-Koozeboom Fe-Ni equal. diagram is untenable, and has been corrected by K. Fe-Ni alloys show Widmannstätten structure from the presence of 2 solid solns. after quenching from above the A_{c3} point. Chem. analyses of the constituents of meteorites showed that tenite contains varying amts. of Ni and more phosphide than camacite. The Ni content of tenite probably depends on the P content, and is normally about 27% at room temp. Magnetic tests indicated that a meteorite contained 2 phases of about 7% and 25% Ni, resp., and these tests did not show the presence of a sep. P compd. Dilatometer tests showed that the tenite did not contain 30% Ni. Scleroscope hardness tests gave irregular results, averaging about the same for camacite and tenite. The microstructure of a meteorite after various heat-treatments showed that after annealing at a high temp., rapid cooling gave the Widmannstätten structure, while slow cooling gave a homogeneous solid soln.; and the Neumann bands were removed by annealing at 560° . P and C are not favorable to the formation of Widmannstätten structure; Mn, Cr and S were also found unfavorable, while Co and generally Cu were not unfavorable. Long exposure to a very high temp. and subsequent rapid cooling produces this structure in meteorites and Fe-Ni alloys. Photomicrographs illustrate the structures observed.

G. F. C.

Season cracking in small-arms ammunition. N. H. MURDZA. *Army Ordnance* 6, 269–72 (1926).—Since the War, a loss of \$7,000,000 or more has resulted from season cracking of small-arms ammunition. The hypotheses that have been advanced to account for season cracking are briefly discussed. The cause may be either mech. or chem. Internal stress in a cartridge case is desirable, and only partial annealing of the neck is permissible. Tests for a stressed condition are metallographic, Hg acceleration, baby Brinell, or taper-tool. An outdoor weathering test for corrosion effects is mentioned. Season cracking did not occur in one lot of old ammunition which was protected from

corrosion by an identifying stain and lacquer. Some Russian cases had been annealed too much so that the bullets were not held properly. Although season-cracking was prevented, 60% of this ammunition was useless. Thicker-walled cartridge cases are desirable, and new rifle designs should allow such a change to be made. G. F. C.

Origin of quenching cracks. HOWARD SCOTT. *Bur. Standards, Sci. Papers* 20, No. 513, 399-444 (1925).—In the investigation of gage steels it was found that certain samples cracked when quenched in oil, but not when quenched in water. A brief review of previous literature is given, but an explanation was not found there. With solid cylinders of an oil-hardening steel contg. 0.9% C, 1.2% Mn, 0.2% Si, 0.5% Cr, and 0.5% W, on continuous quenching with agitation, deep-seated cracks not associated with sharp changes of contour were caused by tangential stress, which was tensional at the surface, and they did not develop to visual size until after the specimens reached ordinary temps. throughout. Cracks occurred only on oil-quenching of cylinders between $\frac{3}{4}$ and $1\frac{1}{2}$ in. in diam., and only on water-quenching for diams. between $\frac{1}{4}$ and $\frac{1}{2}$ in., because under other conditions the surface stresses were compressional. The rare cracks occurring when the surface is in compression start at the center, where the stress is tensional. Permanent tensional stress at the surface is generated in cooling only when the steel is plastically deformed while the coeff. of expansion is negative. An instrument for measuring expansion on air-cooling after quenching is described, and tests of deep-hardening steels with it showed that the transformation Ar_2 occurring at a low temp. is accompanied by an expansion, first linear while the steel is still plastic, and later decreasing. A theoretical study of the stresses developed in terms of the temp. drop or difference between center and surface, at the temp. of effective elasticity of the surface, showed that the surface stress increases, with the temp. drop, to a max. in tension, then passes through zero to a high value in compression, also that under certain conditions the tensional stress is proportional to the linear expansion during Ar_2 , and to the temp. drop. To avoid quenching cracks in pieces of simple shape either a much more rapid quenching medium should be used, or the cooling through the hardening transformation should be retarded by the use of hot oil. The tendency to crack can also be reduced by increasing the alloy content of the steel, or in high-C steel by raising the quenching temp., so as to lower Ar_2 until it is barely completed at ordinary temp. Cracks from temporary tensile stress at the surface may be caused by rapid cooling below Ar_2 and such cooling should be avoided for steels where Ar_2 is high. Similar cracks may also be caused by differential tempering on fast heating of quenched steel. To minimize grinding cracks, hardened tool-steel should be tempered around 150-80°, where a max. contraction occurs, before grinding. G. F. C.

Quenching liquids. J. HÉBERT. *Tech. moderne* 18, 65-71 (1926).—Discussion of the effects of the temp. and compn. of the quenching liquid on the hardness of steels. On quenching in water, increase in temp. up to 30-40° does not affect the hardness; from 30-40° up to 90° the hardness decreases with increase in temp., and from 90° to 100° there is no change. The following solns. give greater hardness than pure water. NaCl (max. at 150 g. per l.), H_2SO_4 (max. at 30 cc. per l.), $K_4Fe(CN)_6$ (effect begins only above 5 g. per l.), Na_2CO_3 (only up to 50 g. per l. with max. at 25 g. per l.), NaOH (effect begins only above 20 g. per l.), NH_4Cl (only up to 150 g. per l. with max. at 50 g. per l.), HCl (only slight increase in hardness, with max. at 50 g. per l.). Addns. of $Ca(OH)_2$, soap and gum arabic decrease the hardness. A. PAPINEAU-COUTURE

Tests on steel poles. ANON. *J. Elec.* 56, 137-43 (1926).—A report on an elaborate test on design, quality of steel, mech. properties, etc. C. G. F.

Changes of length of carbon steels. L. E. DAWKE. *Stahl u. Eisen* 45, 786-8 (1925).—The change of length during slow heating and cooling of a series of C steels contg. 0.06 to 0.75% C was detd. The contraction occurring on heating at 720° diminished with increasing C, but very slowly above the eutectic point. The change is made up of 2 opposing influences, viz., contraction due to the α to γ Fe transition and expansion due to the soln. of pearlitic cementite. In hypereutectic steels the expansion due to the soln. of free cementite increases proportionately to the C content. In the cooling curves the end of the γ to α Fe dilatation is marked by a "hook" for steels contg. more than 0.1% C, which increases with the C content and is due to the delayed formation of pearlite. Curves obtained on tempering steels hardened at 900° and 1100° showed that the increase in vol. on hardening rapidly diminished on tempering. Test-pieces contg. more than 0.25% C hardened at 1100° showed 2 inflections in the tempering curves which were more marked as the C increased. Hypereutectic steels quenched at 1100° showed an expansion at 300° which increased with the C percentage. Four test-pieces contg. 1.7% C were quenched at 900°, 1000°, 1100° and 1200°, resp. The dilatation at 300° increased with rising temp. and the structure was increasingly austenitic.

The expansion at 300° is, therefore, connected with the γ to α iron transformation accompanied by the formation of martensite and agrees with the density curves of Maurel (*C. A.* 4, 1975) and the hardness curves for steels contg. austenite showing a max. at 300–400°.

B. C. A.

Primary etching (of steel). P. OBERHOFFER. *Stahl u. Eisen* 45, 223–4 (1925). Etching expts. were made on Thomas rail steel cast into 100 × 100 mm. section and rolled to 20 mm. square. The cold-forged material showed a clear primary banded structure and the hot-forged specimens an indistinct structure. On annealing the cold-forged steel for 3 hrs. and cooling in air, the structure became indistinct and, on heating the hot-forged steel for a short time above A_{c3} and cooling in air, the structure became clear and more so on quenching from the same temperature. Both the hot-forged and the cold-forged steel after annealing at 900° and cooling in air showed the same primary banded structure. Conclusion: The appearance of clear and indistinct primary banded structure in medium hard steel is conditioned by the form of the secondary structure and depends on the total effect of the primary etching medium in showing up the differences of concn. within the mixed crystals and secondarily in distinguishing between ferrite and pearlite. If the secondary structure is smaller or equal to the primary band width, the structure is clear, if greater, the structure is indistinct. The secondary grain structure is more rapidly increased by high temp. than the primary.

B. C. A.

High-speed steel, its physico-chemical nature and technical properties. G. Z. NESSELSTRAUSS. *Ann. Inst. Phys.-Chem. Anal. Leningrad* 2, 484 (1924).—Investigation of the microstructure and thermal transformations in chrome-W steel contg. 0.4% C, 4% Cr, and 19.5% W renders apparent a rough parallelism between the processes occurring in the steel on cooling and heating, and the transformations taking place in the hypereutectic steel on disturbance of its physico-chem. properties. The most active constituent of high-speed steel is the C, in spite of its small proportion; the presence of Cr increases the soly. of the C in the Fe. The role of the W is to raise the temp. at which the austenite is converted into martensite and thus cause the so-called secondary hardness, which is found to an unimportant degree in ordinary C steel. By suitable thermal treatment it is possible to impart to high-speed steel a very fine and uniform structure free from brittleness, the metal being then unsuitable for the manuf. of high-speed tools.

B. C. A.

Chrome steel for permanent magnets. P. OBERHOFFER AND O. ERMICKE. *Stahl u. Eisen* 45, 537–40 (1925).—Cr steel of the compn.: 1% C, 1.6–2% Cr, 0.25% Mn, 0.15% Si, is used largely in Germany for permanent magnets in place of the more expensive W steel. The metal is usually cast in 220-kg. ingots, which are cleaner, less porous and less segregated than 100-kg. ingots. Annealing at 1150–1200° for 20 hrs. completely equalizes the compn. and structure without affecting in any way the magnetic properties. The ingots are heated to 940–1150° during 30–60 min. for rolling into bars, which are then hardened at the required temp., quenched and tempered. The magnetic properties increase to a max. with rise of hardening temp. and then decrease; the height of the max. depends on the time of heating, quenching temp. and rapidity of quenching. The remanence increases and the coercivity decreases as the temp. of the subsequent tempering is raised, especially between 250° and 350°, corresponding with ptn. of carbide and the development of a troostitic structure. Mech. work produces alterations in the magnetic properties which do not seem to follow any definite law.

B. C. A.

The magnetic properties of nickel steels. J. WULFSCHMIDT. *Krupp. Monatsch.* 6, 228–32 (1925). cf. *C. A.* 19, 3464.—Curves for the variation of magnetization of Ni steels with the Ni content at room temp. as detd. by 4 methods are given and compared. In most cases previous results are confirmed.

C. J. BROCKMAN

Permax, a new ferro-nickel having remarkable magnetic properties—comparison with permalloy. H. TSCHERNING. *J. phys. radium* 6, 300–4 (1925).—The magnetic behavior of a specimen of the new Fe-Ni alloy, Permax, was compared with that of a specimen of Permalloy, by the fluxmeter method. Permax was found to have very low hysteresis at high fields but high hysteresis at low fields. The permeability is high for a field of 1 gauss and the “knee” in the curve occurs at about 2 gauss. At higher fields the permeability is moderate. At low fields there is a very marked “magnetic viscosity.” Permax lacks the remarkable properties of Permalloy.

W. W. S.

The properties and testing of magnetic materials. X. Effects of heat treatment. T. SPOONER. *Elec. J.* 23, 24–9 (1926); cf. *C. A.* 19, 2799.—Curves and tables show the effects of heat treatment upon the magnetic properties of steel. The coercive force, max. permeability and resistivity line up well with the rate of cooling, but the residual induction does not. Certain alloying elements added to C steels have decided effects.

Mn, Ni, Cr, etc., do not essentially alter the transformations referred to but simply slow them up. Irreversible high-temp. magnetic effects are summarized. These elements not only slow up these transformations but reduce the permeability and raise the coercive force for a given C content. Time is as important as temp. in heat treatment. It is necessary to study the effect of heat treatment on the particular size and shape. A brief bibliography is appended.

W. H. BOYNTON

The properties and testing of magnetic materials: Effect of temperature. T. SPOONER. *Elec. J.* **23**, 79-83(1926); cf. *C. A.* **20**, 896

C. G. F.

The relation between the equilibrium diagram and the magnetic susceptibility in binary alloys. HIKOZÔ ENDÔ. *Sci. Repts. Tohoku Imp. Univ.* **14**, 479-512(1925).—The Weiss electromagnetic method of testing was used to det. the relation between magnetic susceptibility and the concn. of binary alloys with more complicated equil. diagrams than the systems investigated previously. The app. used is described and illustrated. The microstructures, elec. resistances and thermal crit. points of some systems were also examd. The magnetic susceptibility-concn. curve for the Cu-Sn system agrees with the Ishihara diagram, except that Cu_3Sn is shown to dissolve 2% Cu. In the Zn-Sn system no soly. of Zn in solid Sn was shown. For a mixt. of 2 constituents the curve becomes straight, while for a solid soln. it is a curved line. The Bi-Sn system was studied by several methods and all agreed in showing solid soly. of 16% Bi in Sn, and of 0.9% Sn in Bi. The Cu-Zn diagram of Imai was confirmed, 3 compds., Cu_2Zn_3 , CuZn_2 and CuZn_4 , being found. The Pb-Tl diagram of Lewkonja was confirmed. The Bi-Pb diagram of Barlow was confirmed except that only 4% Pb was found to be sol in solid Bi. The Sb-Sn diagram of Williams, the Sb-Cu diagram of Reinmann and the Bi-Zn diagram of Arnemann, etc., were all confirmed. In the Sb-Pb system a soly. of 5% Pb in Sb at 250° was found by several methods, but no solid soly. of Sb in Pb. The eutectic contains 12.5% Sb and no compd. is formed. The Bi-Te diagram of Monkenmeyer was confirmed by all the methods of investigation, a compd. Bi_2Te_3 being formed, in which both Bi and Te are slightly sol. The magnetic method did not confirm the complete solid soly. of Cu and Mn as shown by the equil. diagram of the Cu-Mn system.

G. F. C.

Recent advances in the manufacture of ferromagnetic materials. E. GUMLICH. *tech. Physik* **6**, 670-82(1925).—A review dealing with the magnetic properties of com. Fe, electrolytic Fe, various ferrous alloys (contg. Si, Al, Mn, Co, Ni and C) and the so-called Heusler alloys.

H. S. V. K.

The microstructure of aluminum-iron alloys of high purity. F. H. DIX, JR. *Proc. Am. Soc. Testing Materials* **25**, Pt. II, 120-36(1925); cf. *C. A.* **19**, 2803.—In the discussion by McAdam and Dix it was stated that the term "eutectic" was loosely used to describe a kind of structure rather than a definite alloy. Coalescence of the constituents of the Al-FeAl₃ eutectic is favored by the presence in it of 25 times as much Al as FeAl₃. Surfusion gave eutectic structures in alloys not of eutectic compn. and also caused the presence of Al crystals in hyper-eutectic alloys, because of the slight inclination of the line representing the sepn. of Al on the equil. diagram and the steep slope of the similar line for FeAl₃. Surfusion has a similar effect on the eutectic in the Al-Si system. High pouring temp. as well as rapid chilling gave fine eutectic structures with Fe contents above the slowly cooled eutectic compn.

G. F. C.

Transformations of certain aluminum alloys under the effects of deformations. LÉON GUILLET. *Rev. métal.* **23**, 48-52(1926).—Deformation after hardening favors transformations in duralumin, while it apparently has no effect on hardened Al-Cu-Mn alloy (Cu 5.40, Mn 1%). Study of the resistivity does not shed any light on the transformations of these light alloys.

A. PAPINEAU-COUTURE

Study of the system aluminum-zinc. O. TIEDEMANN. *Z. Metallkunde* **18**, 18-21(1926).—Alloys of Al and Zn with Zn ranging from 0 to 20% in increments of 2.5% were studied with respect to strength and elongation after heat treatment and subsequent quenching. Each series was heat treated at 240°, 300°, 350°, 400°, 450° and 500° and detns. were made with immediate quenching and with quenching after 6 weeks. Curves are shown for each temp., strength and elongation being plotted against % Zn, as well as differences in these characteristics with immediate quenching or quenching after 6 weeks. These curves and an equil. diagram are discussed in detail. New equil. relations are found at 275° with 6% Zn.

H. STOERTZ

Hardening of light aluminum-copper alloys containing over 5% of copper. • LÉON GUILLET AND JEAN GALIBOURG. *Compt. rend.* **181**, 1107-8(1925).—Brinell hardness and elec. resistivity for alloys contg. 7-45% Cu, after various heat treatments are tabulated, showing that: quenching and tempering considerably affect the hardness of the alloy, which can often be doubled by the optimum treatment; the resistivity is increased by

quenching and in many cases also by tempering. The latter fact, already observed in the case of duralumin, is abnormal. Micrographic examn. showed that the phenomena are similar to those occurring in duralumin after similar treatment. Accidents occurring with internal-combustion-engine pistons (Cu 12-3%, Al 88-97%) were considerably reduced by quenching at 475° and tempering for 1 hr. at 250°. The investigation furnishes an excellent example of a class of alloys which can be hardened by quenching though they show no transformation point.

A. PAPINEAU-COUTURE

Impact tests according to Schüller-Moser and the impact resistance of a few brasses, copper and aluminum at low and high temperatures. F. SAUERWALD AND H. WIELAND. *Z. Metallkunde* 17, 358-64, 392-9(1925).—This is a study of impact tests on non-ferrous metals and alloys. The total work expended in fracturing a sample is made up of the work required to overcome the elastic resistance of the sample and the hammer, the work required to produce the plastic deformation which takes place in the test piece, and the work involved in overcoming the cohesion of the smallest cross section of the material. The size of the test piece, the wt. of the hammer, the angle of its cutting edge and the method of detg. the vol. of the deformed section are discussed at length. The deformed area can be brought out more plainly by etching and polishing, grinding with emery or coating with shellac. Photographs are shown. The complete impact test involves the detn. of S , the work done by the hammer, S_0 , the work done by the hammer divided by the area of cross section of the test piece; V the vol. of metal flow produced by the blows of the hammer, and S_v , the work done by the hammer divided by V . Brass contg. 58, 63, and 72% Cu is studied, as well as Al and Cu. Curves are plotted showing the variation of impact resistance with diam. of sample, and with variations of temp.

H. STOERTZ

Annealing, quenching and tempering of a few commercial nickel brasses. F. M. OSTROGA. *Rcv. métal.* 22, 776-86(1925).—Three types of brasses: Cu 50.42, 44.70, 39.65; Ni 6.25, 10.34, 14.75; Pb 0.17, 0.21, 0.17, Zn 42.90, 44.10, 45.20%, resp., were investigated by means of the Chévenard differential dilatometer (C. A. 11, 2743), by the Brinell hardness tester and micrographically. By quenching, with or without tempering, it is always possible to harden the metal, as compared with its annealed condition. This hardening is attributable to a structural change and is more pronounced the finer the structure. Quenching gives either the state that is stable at high temps. or the $\alpha + \beta$ state. No martensitic state could be detected after any of the treatments applied. The dilatometric curves are normal. The derived cooling curve shows 2 breaks, the corresponding points of which are generally found on the heating curve as well.

A. PAPINEAU-COUTURE

A study of phosphor bronzes based on thermal investigations of copper-phosphor-tin alloys. L. C. GLASER AND H. J. SEEMANN. *Z. tech. Physik* 7, 42-6(1926).—The authors studied a small part of the Cu-P-Sn diagram contg. the technically important phosphor bronzes. The alloys were made up with pure electrolytic Cu and Sn, and a Cu-P alloy with 15.4% P. A ternary eutectic (80.7% Cu, 4.5% P and 14.8% Sn) is formed at 628°.

H. S. v. K.

Amalgams of gold and mercury. G. T. BRITTON AND J. W. MCBAIN. *J. Am. Chem. Soc.* 48, 593-8(1926).—The system Au-Hg was carefully redetd. for concns. from 0 to 55% Au by analysis of the liquid in contact with the solid phase at temps. up to 410°. The soly. of Au in Hg at room temp. is only 0.2%. The liquidus reaches a max. for 14.6% Au at 342°, indicating the existence of a compd. AuHg₄. A eutectic occurs at a concn. of 22% Au and 320°.

H. S. VAN KLOOSTER

Antifrictional (bearing) alloys, their composition, properties and testing. A. K. ZAITZEV. *J. Russ. Met. Soc.* 1925, Pt. I, 304-58.—Various types of babbitts were tested and analyzed. The results show the possibility of a rational choice of babbitts for practical purposes. An accurate and rapid method for a mechanical test of the materials subject to friction has been worked out. The article is accompanied by a series of tables, charts and drawings.

J. S. JOFFE

Mechanical properties of zinc. G. SACHS. *Z. Metallkunde* 17, 187-93(1925). The hardness, tensile strength, ductility and pliability of Zn at ordinary temps. and at the temp. of liquid air have been detd. after varying mech. and heat treatments. The hardness and tensile strength increase at both temps. with the severity of the rolling. With a slow speed of rolling the sheets are stronger before annealing than after, but with a rapid rate of rolling the annealed sheets are stronger. At -180° the strength of the cold-rolled sheets increases with the rapidity of rolling, whereas that of the subsequently annealed sheets remains const. Strips cut parallel to the direction of rolling are more pliable but have a lower tensile strength than those cut perpendicular to this direction, and this difference is not completely removed by annealing. The tensile strength and

structure of cold-rolled Zn are not affected by aging at the ordinary temp., but aging for 30 min. at 50° results in an increase of tensile strength, ductility and pliability. Heating for short periods at higher temps. results in a slow decrease in the values for the tensile properties and at 350° an extremely rapid fall takes place, and the metal becomes very coarsely cryst. Primary recrystn. commences at 50°, at which temp. the irregular structure of cold-rolled Zn slowly changed to a finely cryst. polyhedral structure. Secondary recrystn. progresses rapidly at about 350° until the whole of the metal is converted into large hexagonal crystals. B. C. A.

Tantalum, tungsten and molybdenum. E. W. ENGLE. *Trans. Am. Inst. Min. Met. Eng.* Mar., 1925 (advance copy), 18 pp.—The phys. properties of Ta, W and Mo are compared with those of Pt, Ni, and Cu, and an account is given of the chief uses of the metals. Ta has a much greater elec. resistance but a smaller temp. coeff. than Mo or W, and is also much softer, its Brinell hardness being only 46 compared with 290 for W and 147 for Mo. W may be readily filed and ground, but cannot be machined easily, whereas both the other metals are readily machinable. Mo is by far the most volatile of the 3 metals and has the greatest tendency to recrystallize on heating. Mo is very resistant to corrosion by HCl, but is markedly attacked by some of the weaker org. acids, while Ta is attacked only by HF. Mo wire wound on a zirconia refractory makes a satisfactory elec. furnace for temps. up to 2000°, providing that an atm. of H is maintained around the heating coil. Ta finds application as an electrode in an electrolytic valve rectifier, a lead sheet being used as the other electrode and "accumulator acid" contg. 1% of FeSO₄ as electrolyte, and also, on account of its great affinity for O, H, and N, as an absorbing medium for the last traces of gas in radio tubes. The presence of more than 0.05% C in Ta may be detected microscopically by the formation of black patches between the crystal grains, such metal may be rolled into sheets, but these are usually brittle and show seams on the surface. A bath contg. 3 lb. of NiSO₄, 6 oz. of MgSO₄ and 4 oz. of boric acid per gal. showed that an adhesion equal to 27 tons per sq. in. could be obtained. There appeared to be a certain amt. of growth of the Fe crystals by the deposition of Ni as well as a keying action of the Ni into the pickled base, but the strength of the joints must be ascribed primarily to actual cohesion between the crystals of the 2 metals. B. C. A.

Action of "hot wall": a factor of fundamental influence on the rapid corrosion of water tubes and related to the segregation in hot metals. C. BENEDICKS. *Trans. Am. Inst. Min. Met. Eng.* Feb., 1925 (advance copy), 30 pp.—Although it is known that dissolved air in water has a serious corrosive effect on water tubes, it is not conceded that the gradual liberation of air from water or the presence of entangled air can account for localized corrosion of, e. g., boiler tubes, and to account for this a condition designated as "hot wall" is introduced. Hot wall is a condition converse to that produced by permitting a gas contg. a vapor to come into contact with a cold object on which part of the vapor will be condensed if the plate is below the dew point. Thus if a liquid (water) contg. a gas (air) comes into contact with a hot plate, a new gaseous phase is produced and bubbles of gas sep. on to the plate. This is supposed to occur in boiler tubes, and the gas bubble being non-conductive causes a hot spot on the tube, and any chemically corrosive action which may be proceeding more or less slowly will be accelerated by the rise in temp. This view may explain the localized corrosion which occurs when different metals are used in construction. The remedy is to remove dissolved air prior to the contact of water with metal tubes. Exptl. data have been obtained by passing water at detd. velocity over heated nichrome strips. The action of the hot wall is a special case only of the spontaneous concn. differences that may occur in a primarily homogeneous soln. when subjected to locally different temps. (Ludwig-Soret action), and the application of this phenomenon to segregation in molten alloys is considered. B. C. A.

The action of water containing ammonia on pipes and boiler plates. M. TILGNER. *Chem.-Ztg.* 50, 48(1926).—Water contg. 8–15 mg. NH₃/l. showed a strong corrosive action, other conditions of use and H₂O compn. begin normal. W. B. P.

The behavior of iron, bronze and brass in solutions of the salts and salt mixtures contained in waste liquors from the potash manufacture at ordinary temperature and at temperatures and pressures prevailing in steam boilers. O. BAUER, O. VOGEL and K. ZEPF. *Mitt. Materialprüfungsamt Kaiser Wilhelm Inst. Metallforschung* 1925, No. 1, 62 pp.—A systematic detn. of iron, bronze and brass corrosion in resting and moving solns. of MgCl₂, NaCl, MgSO₄, Na₂SO₄, CaCl₂, various mixts. of these, in potash waste liquors, in various river waters and in distd. water. A number of tables are given including the exact data for salt concns. used, analysis of the potash waste liquor and the corrosion results obtained over a period of 30 days. The following conclusions are

drawn: Bronze and brass are only slightly attacked by the salts and waters. Mg salts at ordinary temp in a concn. corresponding to 112-9 German degrees of hardness are not dangerous to iron. Mg salts in the feed water to the steam boiler must be regarded as a danger, increasingly so with the concn. The explanation of this is given in the hydrolytic decompn. of Mg salts at high temp. and pressure, producing the effects of acid.

D. THURSEN

Production of oxide films on copper at ordinary temperature. U. R. EVANS. *J. Chem. Soc.* 127, 2484-91(1925), cf. *C. A.* 19, 1398.—E. gives a detailed description of his method for producing oxide films on thin Cu-foil by aerated electrolysis in 0.1 N NaOH soln. The expts. were carried out in open vessels and also in vessels enclosed in glass bell-jars placed in a thermostat. The latter arrangement permitted evacuation and regulated admission of purified air at the bottom of the cathode foil. The coloring is due to the H stored in the Cu. Alternate oxidation and reduction cause the formation of porous surface films of visible thickness showing the well-known interference colors.

H. S. V. KLOOSTER

Tensile properties of soldered joints under prolonged stress. J. R. FREEMAN, JR. AND G. W. QUICK. *Metal Ind.* (New York) 24, 7-10(1926).—Tensile tests of Pb, Sn, and 50-50 solder were made by applying definite stresses to wires 6 in. long and 0.1 in. in diam., and measuring the elongation with time up to 28 days. Pb was found to support a stress of 415 lbs. per sq. in. without failure. Sn showed constantly increasing elongation under stresses greater than 230 lbs. per sq. in., and solder gave the same result under stresses above 70 lbs. per sq. in. The test specimens of soldered joints were lap-joints of galvanized Fe and sheet-brass, each soldered with Sn, 50-50 solder, and 60-40 Pb-Sn, resp. The app. for securing const. pressure and temp. in making the specimen is described and illustrated. No creep was observed in any soldered-joint specimen at shearing stresses up to 400 lbs. per sq. in. No specimen joined with Sn failed at this stress. The joints made with solder showed failures at 400, but not at 200 lbs. per sq. in. The 50-50 solder failed before the 60-40, and the galvanized Fe joints failed before the brass joints.

Fusion welding of aluminum. C. F. NAGLE, JR. *J. Am. Weld. Soc.* 3, No. 3, 39-44(1924); *J. Inst. Metals* 33, No. 1, 513(1925).

E. J. C.

Welding gray cast iron by acetylene. F. POLITZ. *Stahl u. Eisen* 45, 653-8(1925).

The thermal processes in welding gray cast iron were investigated. One end of a rod, 21 mm. diam. and 150 mm. long, was heated by means of an acetylene burner and the temps. at various points throughout its length were detd. From the data thus obtained a series of heating and cooling curves was constructed. The temp. on cooling was equalized throughout the rod in 15 min. When the end was heated to m. p., no temp. above the pearlite point was recorded at 15 mm. distance. This localized heating in welding tends to set up strains which are liable to form cracks. In cold welding the temp. differences in the neighborhood of the weld amount to about 1100°, but in hot welding the whole object is heated to 900°, and the differences are only about 200-250°. Except in highly strained parts, however, cold welding can be carried out without special precautions, as the stresses are not so severe as generally assumed. A no. of welds illustrating correct and faulty work were made and subjected to tensile and hardness tests and metallographic examn. In cold welding the structure of the weld was fine

grained and contained ledeburite, but in hot welding it consisted only of pearlite and graphite. In the latter case the weld was softer but withstood a breaking load 50% greater. Excess of O or acetylene, long heating or overheating deteriorated the weld. The addition of ferric oxide, up to 1.5%, to the welding powder favored the formation of graphite on cooling and softened the weld without reducing its strength. B. C. A.

Lead and silver from sulfide ores. H. HEY. U. S. 1,572,388, Feb. 9. Sulfide ore is heated in the presence of gaseous HCl under non-oxidizing conditions to effect preferential chloridizing of the Pb and Ag present without chloridizing other sulfides in the ore and the Pb and Ag chlorides are then leached out.

Smelting crude zinc-bearing material. W. A. OGG. U. S. 1,573,013, Feb. 16. A retort is charged with a mixt. of Zn-bearing material such as ore or concentrate and reduction fuel such as coal, coke and pitch in such quantity as to produce a vol. of metal vapors in substantial excess of the capacity of the condenser. Spelter is recovered to the full capacity of the condenser and vapors passing from the condenser are further treated for additional recovery of metal values, e. g., by burning them with air. U. S. 1,573,014 specifies a similar process in which a chloride such as NaCl is also used and in which vapors passing through the condenser are deposited as a fume, treated with H₂O to leach out the chloride which the fume contains and in which the wash H₂O is mixed with fresh crude material and fuel and briquetted for use in a subsequent charge in the retort. U. S. 1,573,015 specifies prepg. a charge mixt. contg. the Zn-bearing material, fuel and a fluxing halide such as NaCl or CaCl₂ and subjecting it to a similar operation as in U. S. 1,573,014 except that Zn is pptd. from the wash H₂O from the fume-leaching operation before the wash H₂O is mixed with fresh material.

Treating mixed lead-zinc sulfide ores. N. C. CHRISTENSEN. U. S. 1,572,268, Feb. 9. Finely ground ore is treated with an acid concd. brine to dissolve the Pb and some of the Zn as chlorides and to drive off S as H₂S. The H₂S is treated with lime to form Ca sulphydrate and the latter is used to ppt. (from the brine soln.) first PbS, and then ZnS. Cf. C. A. 19, 2925.

Concentrating oxidized ores by flotation. S. CROASDALE. U. S. 1,573,226, Feb. 16. Ore contg. Cu or other oxidized minerals is subjected to flotation treatment completely to recover these values (without forming any visible film of metallic sulfide on the surfaces of the particles) by treating the ore in the presence of Ca pentasulfide, a frothing agent such as hard wood creosote and a relatively large quantity of petroleum or shale oil or other hydrocarbon material contg. a substantial proportion of olefine hydrocarbons.

Zirconium and other refractory metals. J. W. MARDEN and C. C. VAN VOORHIS. U. S. 1,573,083, Feb. 16. Zr or similar refractory metals are produced by heating together a metal oxide, e. g., ZrO₂, an alkali metal such as Na and an alkali or alk. earth metal halide (the base of which is different from the alkali metal used) such as BaCl₂, in the absence of O and N.

Retort furnace for continuous treatment of ores. W. P. JOBSON. U. S. 1,572,291, Feb. 9.

Apparatus for separating solid particles from blast furnace gases, etc. E. DAN-HARDT. U. S. 1,572,888, Feb. 16.

Side-blast converter furnace for ferrous metals. T. LEVOZ. U. S. 1,572,892, Feb. 16.

Reversible open-hearth furnace for making steel. N. F. EGLER. U. S. 1,572,912 Feb. 16.

Smelting or heating furnace (using coal dust as fuel). E. VOGT and L. KIRCHHOFF. U. S. 1,572,336, Feb. 9.

Tapping trough, slag sweeper, and skimmer for open-hearth furnaces. F. B. MCKUNE. U. S. 1,572,864, Feb. 9.

Gas- or oil-fired detinning furnace. A. W. CALVERT. Brit. 236,677, April 16, 1924.

Steel. T. J. BRAY. U. S. 1,572,179, Feb. 9. After deoxidation of steel in a furnace, steel is poured into a mold and an artificial effervescence is created in the metal immediately following the pouring, *e. g.*, by adding Na_2CO_3 or CaCO_3 .

Open-hearth steel. J. D. JONES and E. E. LITZ. U. S. 1,573,004, Feb. 16. In operating an open-hearth furnace, the bath is heated by a plurality of simultaneously operated and sepd. high velocity flames, circularly arranged and radiating from the wall towards the center of the furnace.

Rust-proofing iron and steel. J. H. GRAVELL. U. S. 1,572,354, Feb. 9. A rust-proofing bath comprises H_2O , H_3PO_4 and NaH_2PO_4 which, combining with pickling and foreign acids, tends to prevent formation of a sludge.

Annealing iron articles. H. T. GRAFTON and C. W. WEESNER. U. S. 1,572,600 Feb. 9. Purified producer gas is used substantially free from O and contg. insufficient moisture to stain the Fe articles being annealed.

Fine powders of metals or other substances. E. PODSZUS. U. S. 1,573,017, Feb. 16. Whirling currents of gas or air of great force and velocity (induced by propeller in a disintegrating chamber) are utilized for disintegrating Cu, tombac, Pb or other materials.

Alloy steel. W. P. WOODSIDE and C. N. DAWE. U. S. 1,572,458, Feb. 9. An alloy steel which is suitable for bolts, gears, bearings, etc., comprises C 0.10-0.23, Mn 0.30-0.60, Ni 1.40-1.75, Mo 0.20-0.30 and Fe 97-98.1%.

Alloys resistant to alkalis. N. V. HYBINETTE. Brit. 236,931, July 12, 1924. Fe is alloyed with Ni 18-40 and Cr 28-40% with or without up to 10% Co and up to 2% Cu. C 1.5, Si 1 and Al and Mn 0.5% each may be present.

Aluminum alloy. A. PACZ. U. S. 1,572,502, Feb. 9. An alloy which is suitable for molds for rubber goods comprises Al 70, Cu 15-27.5 and Si 2.5-15 parts. U. S. 1,572,503 specifies an alloy suitable for die casting, comprising Al with Ni $2\frac{1}{2}$ -10 and Si $2\frac{1}{2}$ % or more. Other metals may be present also.

Aluminum alloy. E. R. CROSBY. U. S. 1,572,382, Feb. 9. An alloy which forms close-grained castings consists mainly of Al together with Si about 5 and Sn about 2%.

Aluminum alloy. R. L. JOHNSTON. U. S. 1,572,357, Feb. 9. An alloy which is silver white and forms good castings comprises Sn 5-10 and Si 5-6%, the balance of the alloy being Al.

Aluminum-copper alloy. Z. JEFFRIES and R. S. ARCHER. U. S. 1,572,487, Feb. 9. Castings are made from an Al alloy contg. Cu 3-5.5% and are heated to about 500-540° for at least 7 hrs. and then cooled, in order to improve tensile strength. U. S. 1,572,488 specifies casting an alloy of Al contg. also about 3-10% of Si and about 5-15% of Zn, then heating the casting to a temp. (about 500-515°) slightly below the m. p. of the eutectic and maintaining the temp. until the Si particles have been sufficiently altered to improve the phys. properties of the casting.

Aluminum alloy. R. L. JOHNSTON, R. S. ARCHER and Z. JEFFRIES. U. S. 1,572,489, Feb. 9. An alloy adapted for chill-casting, etc., comprises Al alloyed with Si 3-10, Cu 2-5, and Zn 15% or less. U. S. 1,572,490 specifies Al alloyed with Si 8. Zn 10 and Cu 2.5%.

Nickel alloys. P. D. MERICA. U. S. 1,572,744, Feb. 9. A "principal melt" such as Ni or Monel metal is deoxidized with Mg and then mixed with molten Al to produce an alloy for steam turbine blades, etc.

Nickel alloy. P. GIRIN. U. S. 1,572,996, Feb. 16. Alloys which resist oxidation comprise Ni 50-80, Cr 8-25, W 0.5-8, Mn 1-5 and C 0.3-1%, together with Fe. Cf. C. A. 19, 2322.

Nickel alloys. J. H. L. DEBARS. U. S. 1,572,593, Feb. 9. Alloys which are suitable for cutting tools comprise Ni 15-30, Cr 40-60 and W 15-40%.

Purifying antimony or its alloys. UNITED STATES SMELTING, REFINING AND

MINING Co. Brit. 236,782, Oct. 16, 1924. Impurities such as As and Cu are removed by treating the molten metal to be purified with NaOH or Na₂CO₃ or equiv. compds. which exert a selective action on the As. Temps. of 480–540° are suitable with NaOH and the material may be agitated mechanically or by air or steam. An inert material such as cement, slag, firebrick, clay or sand may be added to facilitate removal of dross and alkali; Cu may be removed by use of S at 295–315° (preferably before removal of As).

Castings of aluminum-silicon alloys. R. S. ARCHER and J. D. EDWARDS. U. S. 1,572,459, Feb. 9. After the mold is filled with molten alloy, the latter is rapidly cooled to cause the Si to take the form of minute particles.

Casting metal ingots. F. B. MCKUNE. U. S. 1,572,865, Feb. 9. A mold is filled with molten metal and a portion of the metal is chilled in the mold while another portion is maintained hot by flowing a stream of fresh molten metal across it.

Casting copper fins on cast iron cylinders. C. P. GRIMES. U. S. 1,572,428, Feb. 9. Features of heat treatment and mech. arrangement are specified.

Reducing metal oxides. W. B. HAMILTON and F. REID. Brit. 236,739, July 29, 1924. Oxides such as ores of Cr, W, Ni or Mn are added to a reception slag formed on top of a bath of molten metal together with C, in successive charges. Cf. C. A. 19, 630

Removing oxide from ferrous metals. R. PORTER and J. C. WHETZEL. U. S. 1,572,848, Feb. 9. Articles of ferrous metal are first immersed in an alk. soln. such as a 30% NaOH soln. and then pickled in an acid pickling bath.

Pickling metal articles. H. S. MARSH and R. S. COCHRAN. U. S. 1,572,155, Feb. 9. Metals such as steel sheets are pickled in a H₂SO₄ soln. contg. H₂S which serves to prevent spotting.

Apparatus for galvanizing metal sheets. C. PLETSCH. U. S. 1,572,953, Feb. 16

Solder for aluminum, etc. A. L. PENNER. Brit. 236,747, Aug. 7, 1924. See U. S. 1,556,022 (C. A. 19, 3476)

10—ORGANIC CHEMISTRY

CHAS. A. ROUITLER AND C. J. WEST

Siegmund Gabriel. A. Personal part. JAMES COLMAN. **B. Scientific part.** AUGUST ALBERT. *Ber.* 59A, 7–26(1926).—An obituary, with portrait. R. J. C.

Opportunities for research in aliphatic chemistry. J. F. NORRIS. *Ind. Eng. Chem.* 18, 262–4(1926).—The needs of and fields for research in aliphatic chem. are discussed and various problems relating especially to the field of petroleum are briefly outlined.

Ring-chain tautomerism. R. R. GARRAN. *Chem. Eng. Mining Rev.* 17, 452–5 (1925).—Brief discussion of the work on this subject published in some 15 papers by Thorpe and Ingold in *J. Chem. Soc.* since 1922; no specific references are given.

C. A. R.

Conversion of lignified plant matter into coal. III. Sugar formation as an intermediate stage of coal formation. C. G. SCHWALBE and RUDOLF SCHEPP. *Ber.* 58B, 2500–2(1925); cf. C. A. 18, 3047; 19, 2789.—It is universally conceded that the formation of humic acids is a precursor of the process of coal formation. That the humic acids found in nature may be formed from sugars produced by the hydrolysis of cellulose by org. acids is indicated by the fact that from cellulose heated at 170° with 2% (CO₂H)₂ glucose can be isolated as the phenylhydrazone and 4 l. of 1% glucose heated with 80 g. (CO₂H)₂ at 130° yields a brown alkali-sol. humic acid which, pptd. with HCl, well washed and heated at 180° with excess of 35% MgCl₂, yields a coal-like material entirely similar to that previously obtained from cellulose with MgCl₂ and differing from ordinary peat as respects its soly. in NaOH and in the absence of any considerable amts. of C₆H₆- and C₆H₅-EtOH-sol. substances. Cellulose is not of itself alone capable of producing coal. S. and S. believe that lignin as well as cellulose takes part in coal formation, and to test this view they subjected pine wood to carbonization in 2 stages, first heating it with (CO₂H)₂ under pressure and then 8 and 100 hrs., resp., with MgCl₂. The coal-like substances obtained in the 2 cases had the following properties: C 62.2, 71%; H 4, 3.8%; soly. in C₆H₆ 3.4, 5.6; in EtOH-C₆H₆ 11.3, 12.2; coke yield 46.4, 47.1; soly. in concd. Na₂CO₃ 4.9, 2.2. They are closely related, therefore, to the natural coals, standing somewhere between peat and anthracite. C. A. R.

Reduction of aromatic nitro cyano compounds. H. RUPE and H. VÖGLER. *Hel-*

vetica Chim. Acta **8**, 832-8(1925).— o - $O_2NC_6H_4CH_2CN$, shaken in aq. alc. EtOAc with H_2 and "Ni catalyst," freed from Ni and solvents, and treated with Ac_2O , gave o -AcNHC $_6H_4CH_2CN$, while the p -isomer, under the same conditions except that fresh catalyst was added after the reaction became slow, yielded p - $H_2NC_6H_4C_2H_4NH_2$ HCl. Similarly, at first in the absence of H_2O , p - $O_2NC_6H_4CN$ gave p - $H_2NC_6H_4CHO$ HCl while the product from the m -compd. was isolated as m -acetaminobenzaldehyde, m. 122° semicarbazone, yellow-brown, decomp. above 280° . m - $H_2NC_6H_4CHO$ was purified by pptg. from PhH-C $_7H_8$ with ligroin, yellow flocks; *oxime*, yellow-brown, m. 195° . o - $O_2NC_6H_4CN$, in the absence of H_2O , yielded o - $H_2NC_6H_4CONH_2$, sapond. by dil. HCl to NH_4 anthranilate-HCl, the crystal measurements of which are given. o - $O_2NC_6H_4CH:NPh$ in aq. alc. EtOAc yielded o - $H_2NC_6H_4CH_2NHPh$, while o - $O_2NC_6H_4NH_2$ gave o - $C_6H_4(NH_2)_2$. Thus the C : N group is protected from reduction only in the o -derivative.

M. HEIDELBERGER

Catalytic reduction of cyano compounds of naphthalene. H. RUPE AND A. METZGER. *Helvetica Chim. Acta* **8**, 838-48(1925); cf. R. and Becherer, C. A. **18**, 255, and preceding abstr.—In this series the protective action of the NH_2 group on the CN radical was even more marked than in the PhH series, not being confined to o -NH-1,5- $O_2NC_{10}H_6CN$ (I) is best purified by recrystn. from alc., using bone-black; in EtOAc alc.- H_2O , with 2 parts "Ni catalyst" and H_2 it yields 1,5- $H_2NC_{10}H_6CN$; *Bz deriv.*, using $BzCl$ and C_6H_5N , m. $211-2^\circ$, is not reduced further under the above conditions. Similarly, 2,5- and 1,2-I gave the NH_2 , CN derivs. Other groups failed to prevent reduction of the CN group, but modified its course. 1,4- $NCC_{10}H_6SO_3Na$ in H_2O with 2 part-catalyst gave in 4 hrs. a trace of material volatile with steam, and on adding HCl and concg., 4-sulfonaphthomethylamine, needles, quite sol. in H_2O (yield 81%); *Ba salt*, needles, 1,5- $BrC_{10}H_6CN$ (best prepd. in 40-50% yield according to Hausmann, *Ber.* **9**, 154b (1876)), on steam distn. of the reduction products, yielded 12% 1,5-bromonaphthaldehyde, m. $102-3^\circ$, purified over the semicarbazone, m. $257-9^\circ$; *oxime*, m. $133-4^\circ$. The portion of the non-volatile products insol. in hot dil. HCl, freed from impurities sol. in Et_2O , gave 7% di-[5,1-bromonaphthylmethyl]amine, m. 142° ; *HCl salt*, and *nitrate* needles. From the above hot dil. HCl soln. there sepd. on cooling the *HCl salt*, needles, of 5-bromo-1-naphthylmethylamine. The base sinters $138-9^\circ$, m. 141° (decomps.) *nitrate*, *oxalate*. 2,5- $NCC_{10}H_6Br$ gave 15% 5-bromo-2-naphthaldehyde (II), 62% primary base, and 2.5% of what was probably the HCl salt of the sec. base. II, m. 78° , purified over the *oxime*, m. 178° ; semicarbazone, m. 270° , difficultly hydrolyzable phenylhydrazone, m. 151° , almost colorless, turns yellow, then red when exposed to light. 5,2-Bromonaphthylmethylamine, m. $111-2^\circ$; *HCl salt*, *nitrate*, *acid oxalate*, all needles. o - HOC_6H_4CN gave a greenish product from which Ni was removed by addn. of $H_2C_2O_4$ to the dil. HCl soln., leaving di-[o -hydroxybenzyl]amine, m. 162° , difficultly combustible.

M. HEIDELBERGER

Reduction of aliphatic cyano compounds. Cyanoacetylurea. H. RUPE, A. METZGER AND H. VOGLER. *Helvetica Chim. Acta* **8**, 848-52(1925).—At $60-70^\circ$ in 60 part H_2O , with H_2 and 2 parts "Ni catalyst" $H_2NCONHCOCH_2CN$ (I) yielded uracil, (II) according to I + $H_2 \rightarrow H_2NCONHCOCH:NH + H_2O \rightarrow H_2NCONHCOCH_2CH(OH) + NH_3 \rightarrow N.CO.NH.CO.CH_2.CH$, or III $\rightarrow H_2NCONHCOCH:CH(OH) \rightarrow HN.CO.NH.CO.CH:CH$, the first scheme involving a new formula for II. In alc-

H_2O PhCHAcCN yielded PhCH $_2$ Ac in the portion volatile with steam after adding HCl, and, crystg. on the Ni, α -acetophenylacetaldehyde aldimine, PhCHAcCHNH. leaflets, m. 96° , indicating the reduction to have gone according to: PhCHAcCN + $H_2 \rightarrow PhCHAcCH:NH + H_2O \rightarrow PhCHAcCHO + NH_3 \rightarrow PhCa:CHOH + H_2O \rightarrow PhCH_2Ac + HCO_2H$. In alc. H_2O -EtOAc EtCN absorbed only 26% of the theory of H_2 , most being recovered unchanged (cf. also v. Braun, Blessing, and Zobel, C. A. **18**, 675). BuCN gave Am_2NH , b $_p$ $95-7^\circ$; *HCl salt*, decomp. 275° ; *oxalate*, m. $210-11^\circ$. It thus behaved like iso-BuCN (R. and Hodel, C. A. **19**, 825).

M. HEIDELBERGER

Synthetic methanol. R. FABRE. *J. pharm. chim.* [8], **2**, 113-7(1925).—A review
S. WALDBOTT

The photochemical oxidation of methyl and ethyl alcohols by potassium dichromate. MIROSLAV SCHWARZ. *Z. Elektrochem.* **32**, 15-7(1926).—The oxidation of both EtOH and MeOH by $K_2Cr_2O_7$ in light goes only to the corresponding aldehydes. With MeOH, the $K_2Cr_2O_7$ is reduced to Cr_2O_3 ; with EtOH, to a brown compd. of unknown compn. The aldehyde formed is less than that calcd. from the $K_2Cr_2O_7$ reduced; the yield increases as the reaction progresses.

B. H. CARROLL

Catalytic oxidation of vinylalkylcarbinols to vinyl alkyl ketones in the presence of palladium black. RAYMOND DELABY. *Compt. rend.* **182**, 140-2 (1926).—Though previous attempts to obtain vinyl alkyl ketones from the corresponding secondary alcs. had been futile (cf. C. A. **19**, 2185), success was attained by the aid of Pd black prepd. by the reduction of PdCl_2 by HCHO (cf. Breteau, C. A. **5**, 1401). With cold $\text{CH}_2\text{:CHCH(OH)Et}$ and Pd black alone, heat was evolved and rapid conversion to 50% Et_2CO occurred and with secondary satd. alcs., e. g., BuOH , there was no reaction even after boiling several hrs. This indicates that the H atoms of the CH(OH) group are particularly active only when in proximity to a double bond. The best results were obtained by bubbling O into the alc., warm if necessary, passing the O-alc. mixt. over the Pd black (the temp. of the latter being raised progressively to 110°), condensing the gaseous products in CO_2 -snow (maintaining a vacuum of 30-40 mm. throughout the system) and sepg. the H_2O from the supernatant ketone. The latter is best identified by its fixation of Et_2NH on the double bond and formation of a picrate and semicarbazone of this addn. product (cf. Blaise and Marie, C. A. **2**, 2376). $\text{CH}_2\text{:CHCH(OH)Et}$ gave 20% $\text{CH}_2\text{:CHCOEt}$. In prepg. $\text{CH}_2\text{:CHCOPr}$, the catalyst was heated to 100° at the beginning. *Diethylaminoethyl Pr ketone*, b_{20} $92-5^\circ$; *picrate*, m. 81° . The disadvantage of the method is the necessity of reduced pressures. C. C. DAVIS

Action of sodium on alkyl disulfides. C. G. MOSES AND E. E. REID. *J. Am. Chem. Soc.* **48**, 776-7 (1926).—Na and alkyl sulfides in dry Et_2O do not give definite products but most disulfides react readily to give Na alkyl mercaptides. The same products are obtained in abs. EtOH . Mg does not react under these conditions. C. J. WEST

Asymmetric sulfur atom. I. A case of isomerism in compounds with two equal asymmetric sulfur atoms. E. WEDEKIND. *Ber.* **58B**, 2510-8 (1925).— $(\text{CH}_2\text{SEt})_2$, b. $207-10^\circ$, somewhat ill-smelling oil, is obtained in 40 g. yield from 24 g. Na in 96% alc. cautiously treated with 62 g. EtSH and then slowly with 94 g. $(\text{CH}_2\text{Br})_2$, 20 g. allowed to stand 8 days, protected from light and heat, with 38 g. MeI gives 40 g. crude *ethylene bis[ethylmethylsulfonium iodide]*, $(\text{CH}_2\text{SMetI})_2$ (I), sepd. by fractionation from dil. alc. into a higher melting α -form (II), becomes slightly discolored 145° , decomp. 154° , and a β -form (III), decomp. $123-4^\circ$ (yield, 2.5 and 1.5 g., resp., from 10 g. crude I). Both, when pure, are snow-white and extraordinarily easily sol. in H_2O , decomp. when dried on the H_2O bath and become slightly yellow on long standing in the air. When crystd. under the same conditions, II appears under the microscope as very fine, faintly doubly refractive needles in bundles and III as more strongly doubly refracting prismatic rods; of II, 0.74 and 1.64 g. dissolve in 100 cc. of 85 and 75% EtOH , resp., at 18° ; of III, 1.14 and 4.40 g. *Salts* of the 2 forms, other than the iodides, do not differ materially in appearance and decompn. temp.; the following were prepd. ($\text{R} = \text{C}_8\text{H}_{17}\text{S}_2$): RIH_2Cl_6 , m. 191° ; RCDI_4 , decomp. $147-8^\circ$; RPICl_6 , red-yellow decomp. 236° ; RAu_2Cl_4 , golden yellow, decomp. 225° ; *picrates*, $\text{C}_{18}\text{H}_{24}\text{O}_{14}\text{N}_6\text{S}_2$, yellow, m. 170° ; RCl_2O , decomp. 227° . Theoretically, I should exist in 2 inactive (*dl* and *meso*) stereoisomeric forms, but all attempts to resolve either II or III into active antipodes have hitherto failed. The *d-camphorsulfonates*, m. 183° , on fractionation from Me_2CO give fractions all of which show $[\text{M}]_D$ $101.4-107.3^\circ$ in H_2O (calcd. for 2 *d-camphorsulfonate* ions, 103.4°). The *d-bromocamphor- π -sulfonate* of II seps. from Me_2CO contg. a few drops of alc. in long needles which, allowed to stand under the mother liquor overnight, change into thick stout prisms; both forms m. $157-9^\circ$; different fractions show $[\text{M}]_D$ $499.5-538.2^\circ$ (calcd. for 2 sulfonate ions 546°). The isomer from III, m. 160° , $[\text{M}]_D$ $479.6-520.4^\circ$. $\text{CH}_2(\text{CH}_2\text{SEt})_2$, obtained in 16 g. yield from 16 g. Na, 41 g. EtSH and 67 g. $\text{CH}_2(\text{CH}_2\text{Br})_2$, b. $228-31^\circ$, gives with MeI *trimethylenebis[ethylmethylsulfonium iodide]* in needles, m. 112° , which it has not as yet been possible to sep. into isomers. C. A. R.

Further studies in luminescent Grignard compounds. W. V. EVANS AND E. M. DIEPENHORST. *J. Am. Chem. Soc.* **48**, 715-23 (1926).—The property of Grignard compds. of giving off light on oxidation is more general than has been noted, prevailing with aliphatic as well as with aromatic compds. The only Grignard compds. that do not give this light are those in which the Mg is attached to a radical of low mol. wt. A list of 30 luminescent Grignard compds. is given. The RMgBr compds. give the most light, the RMgI compds. are poor light givers, although they are readily formed; the RMgCl compds. are slightly dimmer than the Br compds. The *p*-position ranks first as to light-giving power, with the *o*- and *m*-positions much inferior. A solvent influences the intensity of the light only as it affects the concn. of the Grignard compd. and the speed with which it can be oxidized. Photographs of the chemiluminescence spectrum of the oxidation of *p*- $\text{BrC}_6\text{H}_4\text{MgBr}$, *p*- $\text{ClC}_6\text{H}_4\text{MgBr}$ and α - $\text{C}_{10}\text{H}_7\text{MgBr}$ are given. C. J. WEST

Some alcohols containing the trichloromethyl group. J. W. HOWARD. *J. Am. Chem. Soc.* **48**, 774-5 (1926).—EtMgBr (from 32 g. EtBr) and 37 g. Cl_3CCHO give 13 g. trichloromethylethylcarbinol, b_{680} 99°, d_{20}^{20} 1.488; acetate, b_{680} 164-5°; benzoate, b_{680} 217-8°. Trichloromethylpropylcarbinol, b_{686} 115°, d_{20}^{20} 1.481, in 10-11 g. yield from 33 g. PrBr; acetate, b_{686} 168-9°; benzoate, b_{686} 197-8°. Trichloromethylbenzylcarbinol, b_{686} 97°, d_{20}^{20} 1.365, in 10-11 g. yield from 35 g. PhCH_2Cl ; acetate, b_{686} 159-60°; benzoate, b_{680} 210-1°.

C. J. WEST

Hydrogenation of ketones in the presence of pure and impure platinum blacks. M. FAILLEBIN. *Compt. rend.* **182**, 138-40 (1926).—It has already been shown (C. A. 17, 723; 18, 662) that the nature of the reduction of ketones and aldehydes with Pt black depends upon whether the latter is pure or contains other metals such as Fe. Two suppositions are possible: (1) that the 2nd metal modifies the process of formation of the Pt black and changes its character or (2) that the Pt-Fe mixt. is merely pure Pt black intimately mixed with the 2nd metal. If the latter is true, removal of the Fe without impairing the activity of the Pt black should leave a product with the catalytic activity of pure Pt black which had never contained Fe. It was found possible to ext. most of the Fe with a mixt. of equal vols. of CH_3Ac_2 and HOAc in the presence of air. The Pt black thus obtained was unlike that contg. Fe in its catalytic properties, for it closely resembled pure Pt black prepd. without the addition of any traceous metal. Similar results were obtained with Pt-Al mixts.

C. C. DAVIS

Some amidines of the holocaine type. I. A. J. HILL AND ISADORE RABINOWITZ. *J. Am. Chem. Soc.* **48**, 732-7 (1926).—One mol. equiv. of the appropriate nitrile and alk. in Et_2O , treated with 1.25 equivs. of HCl (cooling) gave the following yields of eth. HCl: acetimino Et, 83%; valerimino Me, 80%; phenylacetimino Et, 85%. $p\text{-H}_2\text{NC}_6\text{H}_4\text{OEt}$ reacts with these salts in dry Et_2O , giving the following bis- $[p\text{-ethoxyphenyl}]$ compds.: acetamidine (I), m. 117-8° (12.3% yield); valeramidine (II), m. 96° (6.7%); phenylacetamidine (III), m. 111° (4.5%). The free imino ethers were liberated from the HCl salts with K_2CO_3 and treated with 1 equiv. of $p\text{-H}_2\text{NC}_6\text{H}_4\text{OEt}$, giving $p\text{-ethoxyphenylacetamidine}$ (IV), m. 111-3° (30% yield); phenylacetamidine, m. 88-9° (15%); valeramidine (V), m. 86° (31%). Propionyl- $p\text{-phenetidine}$, m. 120° (90%); butyryl deriv., m. 108-10° (75%); isovaleryl deriv., m. 122° (65%). These were treated with 1 equiv. of PCl_5 in C_6H_6 and then with $p\text{-H}_2\text{NC}_6\text{H}_4\text{OEt}$, giving sym-bis- $[p\text{-ethoxyphenyl}]$ propionamidine (VI), m. 84° (25%); butyramidine (VII), m. 106° (21%); isovalamidine, m. 108° (20%); $p\text{-ethoxyphenyldiethylacetamidine}$, m. 119-20° (24%). The following phenylureides were prepd.: I, m. 164-5° (quant. yield); II, m. 102-3° (quant. yield); III, m. 118° (52% yield); IV, m. 164° (60%); V, m. 158° (64%); VI, m. 100° (quant.); VII, m. 105° (quant.).

C. J. WEST

Glycerolphosphoric acids derived from lecithin. P. KARRER AND HARRY SALOMON. *Helvetica Chim. Acta* **9**, 3-23 (1926); cf. C. A. 10, 3069.—Ba glycerol- β -phosphate (I) $(\text{CH}_2\text{OH})_2\text{CHOPO}_3\text{Ba}$ and Ba glycerol- α -phosphate (II), $\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CHOPO}_3\text{Ba}$, are easily sepd. since only I with $\text{Ba}(\text{NO}_3)_2$, NaNO_3 or KNO_3 readily forms an insol., well-crystd. double salt (III), $\text{C}_3\text{H}_7\text{O}_6\text{PBa}_2 \cdot \text{Ba}(\text{NO}_3)_2$, 100 cc. H_2O at 18° dissolving 0.8 g. Crystd. Na glycerolphosphate (Kahlbaum) was found to be a mixt. of the α - and β -isomers in which the latter predominates. When used as a quant. estimation of the β -isomer, a soln. of 0.8 g. $\text{Ba}(\text{NO}_3)_2$ in 10 cc. H_2O is added to 1 g. mixt. of I and II in 10 cc. H_2O ; after 12 hrs. the ppt. is filtered, washed with 4 cc. cold H_2O , EtOH, Et_2O , dried and weighed; 0.2 g. is added to this wt. to correct for soly. The % of I in the following phosphatides were found to be as follows: crystd. egg lecithin (cf. C. A. 20, 431) 80, egg lecithin obtained by freezing out from Et_2O 84, abs. alc. difficultly sol. fraction from egg (cephelin ?) 45, abs. alc.-insol. fraction from egg (sphingomyelin ?) 73, lecithin fraction from brain 78, com. egg lecithin 70. I was also obtained from pea lecithin. Ba glycerolphosphates from various com. preps. derived from egg lecithin were found optically inactive (cf. C. A. 14, 1660); however, a 35% soln. of 1 prepn. from crystd. lecithin in a 2-dm. tube gave -0.4° and from this about 80% I was obtained; since I has no asym. structure, II would have an unusually high rotatory power; but when a sample of pure II was prepd. by first sepg. I and then repeatedly recrystg. II it was found to be optically inactive. Because of this it is believed that the optical activity of com. raw materials previously examd. by other investigators is due to compds. other than II. Sapon. of the lecithins was accomplished with cold 10% $\text{Ba}(\text{OH})_2$ (cf. Willstätter and Lüdecke, *Ber.* 37, 3754 (1904)), pptn. of the excess $\text{Ba}(\text{OH})_2$ with CO_2 , concn. of the filtrate by evapn., pptn. of I and II with EtOH, the mother liquors contain considerable glycerolphosphate as choline salt from which II can be obtained by concn. and treatment with alc. $\text{Ba}(\text{OH})_2$. When III is treated with

N H_2SO_4 equiv. to 66% of the Ba, filtered from the $BaSO_4$, evapd. *in vacuo* at room temp. over P_2O_5 , dissolved in abs. alc., filtered and again evapd. as above, the free acid is obtained; this is converted to **I** with $Ba(OH)_2$ in dil. alc. soln. When **I** is converted to the Na salt with Na_2CO_3 or Na_2SO_4 , treated with $AgNO_3$ and then $EtOH$ to ppt. the Ag salt, dried, treated with 8 mol. MeI and then 3 mol. Ag_2O , heated, dild. with Et_2O , the excess MeI distd. off, the residue extd. with Et_2O , the ext. evapd. and the residue distd. *in vacuo*, there is obtained *di-Me glycerol- β -phosphate di-Me ether*, $b_{0.8}$ 126–8° (70% yield), optically inactive. To obtain **II** from a mixt. of raw materials it is best to remove **I** as **III** by adding 80% of $Ba(NO_3)_2$ necessary to convert all of the mixt. to the salt, allow to stand, filter off the **III**, evap. the filtrate, filter, heat the filtrate to ppt. **II**, filter hot, repeatedly dissolve and heat to ppt. (**II** is less sol. in hot soln.). *Di-Me glycerol- α -phosphate di-Me ether* (**IV**) was prepd. by adding a soln. of 2 mol. $AgNO_3$ to the raw material of mixed **I** and **II** in H_2O , adding $EtOH$, filtering off the ppt., washing with 50% $EtOH$, then 95% $EtOH$ and finally with Et_2O , drying *in vacuo* and then methylating as given above for the β -isomer; it $b_{0.8}$ 110–2°, $[\alpha]_D - 3.2^\circ$; it is not certain if this is pure material as the β -isomer might be present in a small amt. Attempts to hydrolyze these di-Me esters to the dimethoxyglycerols were not successful. *Ba glycerol- α -phosphate di-Me ether*, $CH_2(OMe)CH(OMe)CH_2OPO_3Ba \cdot H_2O$, was obtained by heating **IV** in sealed tubes for 24 hrs. with 5% HCl , pptg. the Cl with Ag_2CO_3 , pptg. the Ag with H_2S and adding $Ba(OH)_2$, the anhyd. compd., which may contain the β -isomer as an impurity, gives $[\alpha]_D^{20} 3.11^\circ$. N. A. LANGE

Resolution of α -glycerolphosphoric acid into optically active forms. P. KARRER AND P. BENZ. *Helvetica Chim. Acta* 9, 23–5 (1926); cf. preceding abstrs.—Ba α -glycerolphosphate in cold water was poured into boiling aq. quinine sulfate, the hot soln. was filtered, cooled, the sepd. crystals of *quinine salt* (**I**) filtered, washed with H_2O and dried *in vacuo*; recrystd. from hot H_2O and dried over P_2O_5 *in vacuo* at 100°, it m. 155°; crystd. from $EtOH$, it m. 155°, $[\alpha]_D -144.7^\circ$. Ba α -glycerolphosphate (**II**) is obtained when **I** is treated in hot H_2O with $Ba(OH)_2$ soln. until alk., cooled, the excess Ba pptd. with CO_2 , filtered, the filtrate extd. with $CHCl_3$, the ext. concd. *in vacuo*, and alc. added; a 2% aq. soln. in a 2-dm. tube showed no optical activity. When **II** in H_2O is treated with $AgNO_3$ and $EtOH$ a *Ag salt* is obtained which when dried and treated with 8 mol. MeI, then with Ag_2O , heated 4 hrs., Et_2O added, the Et_2O and MeI removed by distn. and the residue distd. gave *di-Me l-glycerol- α -phosphate di-Me ether*, $CH_2(OMe)CH(OMe)CH_2OPO_3Me_2$, $b_{0.4}$ 110°, $[\alpha]_D -1.76^\circ$ (cf. C. A. 13, 609). N. A. L.

The optical rotation of arabic acid and arabates of alkali metals. M. A. RAKUZIN. *Biochem. Z.* 160, 285–7 (1925).—The $[\alpha]_D$ of arabic acid was found to be -27.86° , a value different from that usually assigned to it. Arabates of the alkali metals showed a lower $[\alpha]_D$ than the free acid, the $[\alpha]_D$ of the arabates rising with the at. wt. of the metal. F. A. CAJORI

A case of mutarotation. Application to the study of the saponification of ethyl oxalate by water and dilute acids. E. DARMOIS. *Compt. rend.* 181, 1137–9 (1925).—It has already been shown (C. A. 19, 786) that $(CO_2H)_2$ reacts with NH_4 molybdomalate with a resulting change in the rotatory power of the soln. If NH_4 molybdomalate is treated with a sol. ester of $(CO_2H)_2$ instead of $(CO_2H)_2$ itself, the depression of the rotatory power is no longer instantaneous, the rate of change depending upon the concn. of the ester and upon the temp. The max. *l*-rotatory effect is, however, the same as that caused by $(CO_2H)_2$, indicating that progressive sapon. of the ester occurs. This offers a means of studying the *sapon. of oxalic esters*, e. g., $(CO_2Et)_2$. It was further shown that dil. aq. $(CO_2Et)_2$ on standing undergoes a depression in its rotatory power, this change increasing with time and that if this soln. is mixed with NH_4 molybdomalate the rate of change of the rotatory power of the mixt. depends upon the preliminary time of standing of the $(CO_2Et)_2$. This was due to the formation of HO_2CCO_2Et , which in independent expts. was found to react with great rapidity with NH_4 molybdomalate, the time required for a HO_2CCO_2Et soln. of $1/3$ the concn. of a $(CO_2Et)_2$ soln. to annul the rotation of an NH_4 molybdomalate soln. being only $1/2000$ that required by the $(CO_2Et)_2$. The sapon. of $(CO_2Et)_2$ by 0.05 N HCl is almost twice as rapid as in H_2O , the H^+ ion being an active catalyst and sapon. in H_2O being auto catalytic. C. C. DAVIS

A new method for preparing *l*-tartaric acid. KNUT PARCK. *Svensk Kem. Tids.* 37, 249–51 (1925).—The *dl*-acid is treated with α -benzylphenolphthaleinamine in H_2O , giving the *l*-tartrate of d -benzyl phenolphthaleinamine, m. 72° (yield 18%), which is recrystd. on the water bath. The acid is sepd. as $Pb[CHOHCO_2]_2$. A. R. ROSE

Reactions of carbon disulfide. I. With ammonium hydroxide. E. WERTHEIM.

J. Am. Chem. Soc. **48**, 826-30 (1926).—A soln. of 200 cc. NH_4OH (d. 0.90) and 40 cc. CS_2 , shaken 2 hrs. on a Camp machine or allowed to stand 10-15 hrs. with frequent shaking, gives, when shaken with MeI , 51.5% of Me trithiocarbonate, which decomps. partially on distn. EtBr gives 44% of the *Et ester*, which also dists. with decompn. The *benzyl ester* results in 48% yield. Solns. which have stood for a few days show evidence of contg. NH_4SH in small amts. After 1 month there were obtained 33% of EtSH and 42% Et_2S_2 :C.S. PhCH_2SH was obtained in 40% yields. After 3-4 days very small amts. of H_2S are evolved; this is present in considerable proportions after a week. The reaction between NH_3 and CS_2 assumes entirely different equil. in abs. EtOH and in solns. contg. H_2O . BzH (20 g.), 20 g. CS_2 and 150 cc. NH_4OH give after 24 hrs. 50% of thiobenzaldine (Laurent, *Ann.* **38**, 323 (1841)). C. J. WEST

Acetyl derivatives of thiourea and urea. Constitution of thiourea. ALBERT HUGERSHOFF. *Ber.* **58B**, 2177-87 (1925); cf. Kohmann, *C. A.* **9**, 2654; Werner, *C. A.* **11**, 252.—From 30 g. thiourea (I) and 45 g. Ac_2O on the H_2O bath are obtained unchanged I, 5 g. of the mono-Ac deriv. (II), m. 165-6°, of I, and 35.5 g. of a "tri-Ac deriv." $\text{C}_3\text{H}_3\text{N}_3\text{O}_3\text{S}_2$ (III), yellow, m. 151-2°, 60 g. I and 120 g. Ac_2O give 91 g. III and 8.8 g. II, while 3 g. I with 9 g. Ac_2O gives 4.5 g. III, which is also obtained in 2.9 g. yield from 1.18 g. II and 1.60 g. of the di-Ac deriv. (IV) of I in boiling alc. III dissolves with yellow color in exactly 2 mols. of cold N NaOH and is reprecipitated by 2 equivs. N H_2SO_4 , on standing several days the yellow ppt. gradually changes into the white needles of II. If the yellow NaOH soln. is heated to boiling, addn. of 2 equivs. H_2SO_4 produces traces of H_2S and, on cooling, a much smaller ppt. of III; evapn. of the mother liquors and ppt. leaves a residue from which III and I can be isolated by successive extrn. with EtO and alc. III dissolves immediately, without color, in 25% NH_4OH and evapn. yields I. It likewise dissolves at once in 94% H_2SO_4 with evolution of heat and elimination of AcOH and on pouring into H_2O yields 77.62% II. With PhNH_2 in EtO 8.34 g. III yields 6.0 g. II and 3.12 g. AcNHPh ; with $p\text{-MeC}_6\text{H}_4\text{NH}_2$, 5.0 g. II and $\text{AcNH}(\text{C}_6\text{H}_4)\text{Me}$. $\text{C}_6\text{H}_5\text{N}$ does not react with III. III (40 g.) slowly dissolves in 250 cc. H_2O on the H_2O bath, the yellow soln. gradually becoming lighter in color and finally almost colorless after 4 hrs.' heating; a little H_2S and S and 31.3 g. II are formed. From 3 g. II and 9 g. Ac_2O on the H_2O bath is obtained 3.1 g. IV, m. 150-1°, which dissolves in 1 mol. cold NaOH and is reprecipitated by 1 equiv. H_2SO_4 , but if the soln. is heated to boiling II seps. on cooling; the II again dissolves in 1 mol. NaOH and on boiling yields I. With PhNH_2 and $p\text{-MeC}_6\text{H}_4\text{NH}_2$ on the H_2O bath IV smoothly yields II and the corresponding AcNHR ; with boiling H_2O it gives II. I and IV do not react with each other in warm alc. II in 25% NH_4OH gives I, which is also obtained with dil. HCl . I cautiously fused and then cooled solidifies to an apparently homogeneous cryst. mass which with Ac_2O on the H_2O bath yields 44.7% II. H. explains the above facts by assuming that I has the dimeric structure $\text{H}_2\text{NC}(\text{NH})\text{SH} \cdot \text{H}_2\text{NC}(\text{NH})\text{SH}$, being a salt-like compd. in which half of the mol. functions as a base, the other as an acid. Such a structure accounts for the formation of III on acetylation and the non-formation of IV until the salt-like union has been broken (e. g., by the addn. of a stronger acid). The fact that the m. p. and crystal form of I change when it is fused and resolidified and that the solidified melt gives II on acetylation is due, according to H., to rearrangement, during the fusion, of the basic half of I which, however, remains bound to the acid half, thus preventing the salt-like combination of the I with itself. On the basis of his addn. theory as to the acetylation of derivs. of I (cf. Gibson, *Diss. Göttingen*, 1901), H. assigns to IV the structure $\text{AcN}:\text{C}(\text{SH})\text{NHAc}$. Unlike I, urea, being unable to form a salt with itself, does not yield a tri-Ac deriv.; when it is heated with Ac_2O , a vigorous reaction sets in suddenly at about 120-30° and on cooling the mono-Ac deriv. seps. in 32% yield; Werner's yield of 78% with H_2SO_4 can also be obtained without H_2SO_4 by cautious heating on the H_2O bath, but the di-Ac deriv., to which H. gives the structure $\text{AcNHC}(\text{NAc})\text{OH}$, could be obtained only with H_2SO_4 . The Ac group in the mono-Ac deriv. is held very firmly; heating with PhNH_2 at 170° gives NH_3 and sym. acetylphenylurea, m. 183°. C. A. R.

Synthetic glucosides of pyrimidine derivatives. I. Synthesis of methylisocytosine- β -D-glucoside. AMANDUS HAHN, H. FASOLD AND L. SCHÄFER. *Z. Biol.* **84**, 35-40 (1926).—The Ag salt ($\text{C}_4\text{H}_6\text{N}_3\text{OAg}$) of methylisocytosine is formed by the interaction of the NH_4OH soln. of methylisocytosine with AgNO_3 . 10 g. of the dried Ag salt is refluxed for 1 hr. with 180 cc. dry xylene contg. 17 g. acetobromoglucose. The mixt. is filtered while hot into 1800 cc. petroleum ether. White or pale yellow amorphous flakes sep. These are washed well with petroleum ether and added slowly to 150 cc. of satd. alc. picric acid. The picrate of the tetraacetylglucoside (m. 150°) is formed and may best be recrystd. from hot alc. From it the free glucoside may be obtained.

The dried CHCl_3 soln. of the picrate is poured slowly with const. stirring into petroleum ether. Free tetraacetylmethylisocytosine-*d*-glucoside forms needles, m. $442-5^\circ$. It is slightly sol. in water and easily sol. in MeOH and EtOH, is *l*-rotary ($\alpha_D^{25} = -19.1^\circ$), does not reduce Fehling soln. By boiling 1 min. with *N* HCl glucose is split off. From the Ac product methylisocytosine-*d*-glucoside may be prepd.: 6 g. of the free Ac deriv. in 180 cc. MeOH is mixed with 20 cc. of 10% NH_3 in MeOH. After 16 hrs. at 4° the crystals of the methylisocytosine-*d*-glucoside (m. 190°) form. It is sol. in water and slightly sol. in MeOH and EtOH, is *l*-rotatory ($\alpha_D^{24} = -66.91^\circ$), reduces Fehling soln. only after heating with *N* HCl.

FRANCES KRASNOW

Reducing power of the methylated sugars. GÁZA ZEMPLÉN AND GÉZA BRAUN. *Ber.* **58B**, 2566-70 (1925).—The Irvine method for detg. the structure of disaccharides (hydrolyzing the completely methylated disaccharide and isolating the cleavage products in substance) requires considerable amts. of material. It occurred to Z. and B. that if the reducing powers of the different trimethylglucoses formed in the hydrolysis of various reducing disaccharides differ sufficiently the point of union of the 2 glucose components in the disaccharide might be detd. with as little as 0.1 g. of the latter. Under identical conditions of hydrolysis (2.5% HCl and 3 hrs' boiling) the following results were obtained (reducing power of glucose according to Bertrand = 100): 2,3,5-trimethyllevoglucosan (I) 10.6; 2,3,5-trimethylglucose 9.8; 2,3,5-trimethylmethylglucoside 9.4; 2,3,6-trimethylglucose 27.1; 2,3,5,6-tetramethylglucose 13.6; 2,3,5,6-tetramethylmethylglucoside 12.5; heptamethylmethylgentiobioside 12.1; heptamethylmethylcellobioside 20.2. The I, obtained in 70% yield from 12 g. levoglucosan in 9 cc. H_2O treated dropwise with 39 cc. Me_2SO_4 (neutralized with NaOH) and, in the course of 1.5 hrs., with 70 cc. of a soln. of 100 g. NaOH in 175 cc. H_2O , then heated 0.5 hr. on the H_2O bath, and extd. with CHCl_3 , b_D^{20} $170-80^\circ$ (bath temp.), m. 66° , $[\alpha]_D^{17} -59.4^\circ$ (H_2O), $[\alpha]_D^{16} -58.95^\circ$ (abs. alc.), $[\alpha]_D^{17} -58.92^\circ$ (CHCl_3).

C. A. R.

Synthesis of a disaccharide glucoside. BURCKHARDT HELFERICH, WILHELM KLEIN AND WILHELM SCHÄFER. *Ann.* **447**, 19-26 (1926); cf. *C. A.* **19**, 250.—The previously prepd. triphenylmethyltriacyl- α -methylglucoside with 4 mols. PBr_5 on the H_2O bath for 20 min. gives 21% of acetodibromoglucose, thus establishing the position of the Ph_3C residue as in the 6-position. By using 1 mol. PBr_5 and heating 5-10 min. there results a mixt. of Ph_3CBr and triacyl- α -methylglucoside 6-bromohydrin; the Ac groups are removed by satg. the MeOH soln. at 0° with NH_3 and the resulting product is treated with BzCl , giving 50% of 2,3,5-tribenzoyl- α -methylglucoside 6-bromohydrin, m. 122° , $[\alpha]_D^{18}$ 90.9° ($\text{C}_6\text{H}_5\text{N}$); this was also obtained from 2,3,5-tribenzoyl- α -methylglucoside, m. 143° , with PBr_5 . Reduction with Zn in AcOH gives 75% of tribenzoyl- α -methyl-*d*-isorhamnoside, m. $139-40^\circ$, $[\alpha]_D^{19}$ 106.7° , which is sapon. by NH_3 in MeOH to α -methyl-*d*-isorhamnoside, b_1 162° , m. $98-9^\circ$ (80% yield) and further by 10% acid to *d*-isorhamnose, identical with Fischer's product.

C. J. WEST

Synthesis of gentiobiose. BURCKHARDT HELFERICH, KARL BAUERLEIN AND FRIEDRICH WIEGAND. *Ann.* **447**, 27-37 (1926).—Sapon. of acetofluoroglucose by 1% MeONa in abs. MeOH gives 84% of *d*-glucosyl fluoride, m. $118-25^\circ$, has a normal mol. wt in H_2O , $[\alpha]_D^{18}$ 96.7° (H_2O), is relatively stable towards alkalis, reduces Fehling soln. in the heat and with BzCl in $\text{C}_6\text{H}_5\text{N}$ yields a *tetra-Bz* deriv., m. $110-2^\circ$, $[\alpha]_D^{22}$ 110° ($\text{C}_6\text{H}_5\text{N}$); with $(\text{PhO})_2\text{Ba}$ it gives β -phenolglucoside. Ph_3CCl in $\text{C}_6\text{H}_5\text{N}$ gives 6-*triphenylmethylglucosyl fluoride*, softens 135° , m. 140° (decompn.), $[\alpha]_D^{14}$ 58.4° ($\text{C}_6\text{H}_5\text{N}$), whose *tri-Ac* deriv., m. $147-8^\circ$, $[\alpha]_D^{20}$ 119.6° and *tri-Bz* deriv., m. about 95° , $[\alpha]_D^{18}$ 75.1° ($\text{C}_6\text{H}_5\text{N}$); satg. a CHCl_3 soln. with HCl and allowing to stand 25 min. at room temp. gives 2,3,5-tribenzoylglucosyl fluoride, which was not purified but condensed with acetobromoglucose, giving 6-[*tetraacetyl- β -glucosido*]-2,3,5-tribenzoylglucosyl fluoride, m. $195-6^\circ$, $[\alpha]_D^{23}$ 15° ; with NH_3 in MeOH this yields 95% of gentiobiosyl fluoride, sinters 180° , decomps. $215-20^\circ$, $[\alpha]_D^{20}$ 33.47° ; hepta-Ac deriv., m. $162-3^\circ$; CaCO_3 in H_2O gives gentiobiose, identified as the octaacetate, m. $190-2^\circ$ and the osazone, m. $170-3^\circ$. Gentiobiose is, therefore, a β -6-glucosidoglucose.

C. J. WEST

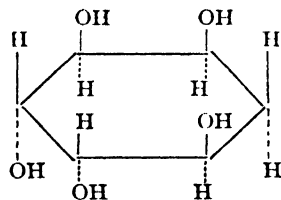

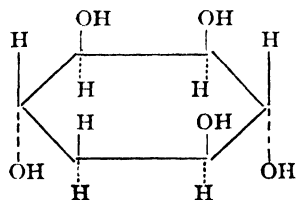

New syntheses of isomaltose and of gentiobiose. AMÉ PICTET AND ALFRED GEORG. *Compt. rend.* **181**, 1035-7 (1925).—Di-levo-glucosan (cf. Pictet, *C. A.* **16**, 2313) is an anhydride of isomaltose and can be converted to isomaltose by digesting with a small amt. of concd. HCl at room temp., evapg. *in vacuo* with KOH, dissolving in H_2O , adding Ag_2CO_3 , filtering and evapg. A mixt. of glucose and isomaltose is obtained from which the glucose is removed by fermentation. Instead of isomaltose being a direct product of the partial hydrolysis of di-levo-glucosan it is possible that hydrolysis is complete,

with glucose as sole product and that the glucose is then converted to isomaltose by HCl. This was disproved by the fact that di-levo-glucosan and AcBr gave on standing and pouring on ice a white powder (by analogy probably an octaacetate of isomaltose bromohydrin) which on sapon. with $\text{Ba}(\text{OH})_2$ gave isomaltose. This synthesis should be of value in detg. the constitution of isomaltose. Acetylation of isomaltose prepd by the method of Fischer, with Ac_2O and NaOAc , gave 2 products: (1) about 97% of a hitherto unknown acetate of isomaltose and (2) about 3% of the β -octaacetate of gentiobiose (cf. C. A. 9, 1181). Sapon. of the latter gave gentiobiose. This indicates that in the prepn. of isomaltose from glucose by the method of Fischer, a small amt of gentiobiose is formed, which represents the 1st synthesis of gentiobiose ever accomplished by purely chem. means.

Investigations on cellulose and lichenin by use of X-ray spectrum. E. OTT. *Helvetica Chim. Acta* 9, 31-2 (1926).—By means of the Debye and Scherrer method of crystal analysis and using a tube with a Cu target, the reflection angles for cellulose (from H_3PO_4 pptn.), oxycellulose and hydrocellulose are found to be identical, thus establishing the identity of the cryst. portions of these substances and the cryst. substance in lichenin.

Amylooctadextrin. PETER KLASON AND KNUT SJÖBERG. *Svensk Kém. Tids.* 37, 290 5 (1925). The discussion in this paper pertains to terminology and leads to the term amylooctadextrin for the amyloextrin yielding disaccharides on further digestion. Enzymic digestion ends with a resistant residue, $(\text{C}_{12}\text{H}_{20}\text{O}_{10})_2$, which is $1/2$ of the dextrin. The dextrin is considered as $(\text{C}_{12}\text{H}_{20}\text{O}_{10})_4$, mol. wt. 2610.

The configuration of *d*-quercitol. P. KARRER. *Helvetica Chim. Acta* 9, 116 7 (1926).—Of the 10 configurations possible for *d*-quercitol (I) 4 are eliminated on the grounds of symmetry. Four of the remaining 6 are eliminated by the fact that I yields mucic acid on oxidation (Kiliani and Scheibler, *Ber.* 22, 517 (1889)). I, therefore, has one of the following configurations

REYNOLD C. FUSON

Dinitro-sym-trihydrazinobenzene and several other derivatives of dinitro-trichlorobenzene. W. BORSCHIE AND W. TRAUTNER. *Ann.* 447, 1-18 (1926).—1,3,5-tri- $(\text{O}_2\text{N})_2\text{C}_6\text{HCl}_3$ (I) and $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ in EtOH give the difficultly sol. hydrazine salt, reddish brown, m. 169° (decompn.), of nitrodichlorobenzazimidole, yellow, m. 196° (decompn.). II (below) and $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ in hot EtOH give 80% of dinitro-sym-trihydrazinobenzene, orange-red, explodes without melting. I and EtOH- NH_3 3 hrs. at 100° give a mixt. of 1,3-diamino-4,6-dinitro-5-chlorobenzene, yellow, turns brown at 185° and m. 206° (decompn.), and 1,3,5,4,6- $(\text{H}_2\text{N})_3\text{C}_6\text{H}(\text{NO}_2)_2$, decomp. about 298° . I and piperidine in EtOH contg. AcONH_4 give the yellow 1-piperidino-4,6-dinitro-3,5-dichlorobenzene, m. 108° ; increasing the amt. of piperidine gives the 1,3,5-tripiperidino deriv., citron yellow, m. $147-8^\circ$. All reactions between I and PhNH_2 give the trianilino deriv., m. $179-80^\circ$; the di-*p*-toluidino deriv., bright red, m. 231° ; di- β -naphthylamino deriv., dark red, m. 225° (decompn.). AcONa and AcNH_2 , 30-40 min. at 160° , give dinitrodichlorophenol, yellow, m. 120° , analyzed as the *p*-anisidine salt, yellow, m. 195° (decompn.). PhONa gives the 1-*Ph* ether, m. 108° . I, Na and Ph OH (excess) on the H_2O bath give 2,4-dinitro-1,3,5-chlororesorcinol di-*Ph* ether, m. $129-30^\circ$. If the reaction mixt. is finally heated to 125° for 4 hrs., there results dinitrochloroglucitol tri-*Ph* ether (II), m. $110-1^\circ$. $\text{CHNa}(\text{CO}_2\text{Me})_2$ and I in EtO give a mixt. of di-*Me* 2,4-dinitro-3,5-dichlorophenylmalonate, m. 132° , and a di-*Me* 2,4-dinitrochlorophenylmalonate (?), brownish, m. 105° ; the 5-*Cl* deriv., prepd. from 1,3,4,6- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{Cl}_2$, yellow, m. $70.5-1.5^\circ$. Et 2,4-dinitro-3,5-dichlorophenylacetate, m. 124° . Nitration of 3,5,4- $\text{Cl}_2(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Me}$ gives 2,4-dinitro-3,5-dichlorotoluene, m. 127° . 3,5,2,4- $\text{Br}_2(\text{O}_2\text{N})_2\text{C}_6\text{HMe}$ and EtOH- NH_3 give 3,5-diamino-2,4-dinitrotoluene, orange-yellow, m. 210° ; the 3,5-dianilino compd., garnet-red, m. $163-4^\circ$; 3,5-dihydrazino deriv., dark red with 2 H_2O , decomp. 173° ; an excess of $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ heated several hrs. gives a methylhydrazinonitrobenzazimidole, bright red, decomp. 176° . EtONa or PhONa does not give characteristic products.

The *di-Ac deriv.* of 3,5,4,2-Br₂(O₂N)(H₂N)C₆HMe, m 170°. 3,5,2,6-Br₂(O₂N)₂C₆HMe and EtOH-NH₃ give impure NH₃ derivs.; the 3,5-*di-p-toluidino deriv.*, orange, m. 191°. N₂H₄·H₂O gives 7-methyl-6-nitro-1-hydroxy-5-bromobenzotriazole, decomp. 236°. EtONa gives 1-methyl-2,6-dinitro-5-bromophenyl 3-Et ether, m. 133°. C. J. WEST

Infra-red absorption spectra of organic derivatives of ammonia. III. Di- and triphenylamine. F. K. BELL. *J. Am. Chem. Soc.* **48**, 813-7(1926); cf. C. A. **20**, 841.—The infra-red absorption spectra, between 1 and 12μ, of molten Ph₂NH (65°) and Ph₃N (145°) are reported. They show, in the region between 2.8 and 3.4μ, the same qual. differentiation between PhNH₂ and Ph₂NH and Ph₃N as in the case of PhNH₂ and the alkyanilines. The significance of the absorption spectra of these compds. in connection with the study of the 3.3μ band of the alkyanilines is indicated. IV. Mono-, di-, and tribenzylamine. *Ibid* 818-23.—The infra-red absorption spectra of PhCH₂NH₂, (PhCH₂)₂NH and (PhCH₂)₃N are reported between 1 and 12μ, the (PhCH₂)₃N being examd. at 105°. These compds. follow, with certain qualifications, the same qual. differentiation previously found to exist between the 3 classes of amines of the aryl and arylalkyl types. In (PhCH₂)₂NH and (PhCH₂)₃N both the 3.3μ band and the 3.5μ band have been resolved. A new band characteristic of the C₆H₅ nucleus has been located at 5.1μ. C. J. WEST

Mechanism of the formation of triphenylguanidine and phenylthiocarbimide from thiocarbanilide. W. J. S. NAUNTON. *J. Soc. Chem. Ind.* **45**, 34-5T(1926).—It is probable that the (PhNH)₂CS momentarily forms carbodiphenylimide, which then combines with the mercapto form of the (PhNH)₂CS to give an unstable S compd., which breaks down into triphenylguanidine and phenylthiocarbimide. T. S. CARSWELL

Standardization of the Sandmeyer reaction, with special applications. H. S. FRY and I. W. GROTE. *J. Am. Chem. Soc.* **48**, 710-4(1926).—Cl, Br and I introduced into the *p*-haloamines give practically identical av. yields of the dihalobenzenes when the diazonium salt is added to either a hot or cold CuX soln. The av. yield for the 9 possible replacements at 0° to 5° is 76%, as compared with 74% if the same replacements are made at 100-5°, the max. difference in any single case was only 10%. The character of the halogen atom already present in the *p*-haloaniline or the presence of a NO₂ group as in *p*-O₂NC₆H₄NH₂ appears to have little if any effect upon the yield of the *p*-halogen deriv. The yields of the *o*-, *m*- and *p*-C₆H₄X₂ and the *o*-, *m*- and *p*-Cl and BrC₆H₄NO₂ are greatest when Br and least when Cl replaces the NH₂ groups. With the single exception that *m*-ClC₆H₄NH₂ gave a greater yield of *m*-C₆H₄Cl₂ than of *m*-ClC₆H₄Br, the general rule appears to hold that the yields of the substituted derivs., from the point of view of the halogen atom introduced, follow the relative order Br > I > Cl. The variations, however, between the 2 extremes are slight in most cases. The *o*- and *m*-ClC₆H₄NH₂ gave markedly lower yields of the corresponding C₆H₄Cl₂ and ClC₆H₄Br than did the *p*-, and some 25% lower than the corresponding products obtained from the O₂NC₆H₄NH₂. The resp. isomeric products are formed, however, in both cases in the following relative quant. order: *p* > (or =) *o* > (or =) *m*. CuCl₂ and CuBr₂ may be substituted satisfactorily for CuCl and CuBr in the standardized cold method as applied to the *p*-haloanilines. The yields with CuCl₂ are 20-30% lower than those obtained with CuCl. Conversely the yields with CuBr₂ are 6-7% higher than those obtained with CuBr. C. J. WEST

Nitro- and aminoformazyls. EUG. BAMBERGER, ROB. PADOVA and ERNEST OERMEROD. *Ann.* **446**, 260-307(1925).—An improved method is given for the prepn. of C nitroformazyl (I). On heating with AcOH or better with a mixt. of AcOH, Me₂CO and AmNO₂, there results C-hydroxydiphenyltetrazolium betaine (II), explodes 176°; *HCl salt*, m. 193°; *perchlorate*, explodes 194°; *iodide*, yellow; *picrate*, golden yellow, m. 169° (decompn.); *chloroplatinate*, flesh colored, m. 196° (decompn.); *Hg salt*, (C₆H₅N₄O)₂·HgCl₄, m. 209.5°; if the prepn. of II is carried out in AcOH-H₂SO₄ there results as a by-product, a compd., C₇H₅N₃O₂, m. 85-86°, which was not further studied. Reduction of II by H₂S in NH₃-EtOH gives OC(NHNHPh)₂, m. 171°. whose *dinitrosamine* m. 95°, it is very unstable and soon no longer gives the Liebermann reaction; in EtOH Cu(OAc)₂ gives a dark red, then pale violet ppt.; HgCl₂ gives a violet-blue, unstable ppt. AgNO₃ gives a violet soln. from which a dark gray ppt. seps. Oxidation gives II. H₂O₂ gives diphenylcarbazone, m. 150°, whose *di-Bz deriv.*, m. 265.5-6.5° and is also obtained from BzCl or Bz₂O and II. Reduction of II by H₂S-NH₃ in EtOH in the cold gives dihydroformazyl mercaptan, m. 164-5° (decompn.), crystg. with 1 Me₂CO, identical with Fischer's diphenylsulfocarbazine (*Ann.* **190**, 118(1878)); *formazyl mercaptan*, PhN:NC(SH):NNHPh, dark violet, nearly black needles with steel-blue luster, m. 178° (*Cu salt*, greenish black needles with metallic luster, m. 191.5-2°; *Pb salt*, red, m. 230°, decomp. 235°; *Hg salt*, decomp. about 220°; *diiodide*, brownish green, m.

135°); further oxidation of these products gives *diphenyltetrazolium thiobetaine*, pale yellow, explodes 180.5° (depends on rate of heating). Reduction of I with NaSH in $\text{Me}_2\text{CO}-\text{NaOH}$ gives *C-aminoformazyl (formazylamine) (III)*, crystg. with 1 H_2O , dark brownish red powder, m. 135–6° (decompn.); the warm aq. soln. is colloidal; it crystals from Me_2CO or CHCl_3 with solvent of crystn.; concd. H_2SO_4 gives a violet-blue soln. it dyes silk in a dil. acid bath a reddish brown; the aq. soln. reduces AgNO_3 in the cold the *HCl salt (IV)* ppts. from Et_2O in violet scales, m. 141–2°; the red MeOH or EtOH soln. deposits the base upon addn. of H_2O . III and Ac_2O give *phenylazophenylmethyl triazole*, m. 178–8.5°; the color varies from canary-yellow to orange-yellow, depending upon the solvent. Heating the IV with concd. HCl gives *C-amino- α -chloroformazyl*, Bordeaux-red, crystg. with 1 EtOH , m. 146° (decompn.), gives a deep violet-red soln. in 2 N NaOH , isolated through the *HCl salt*, turns red 110°, m. 175–6° (decompn.). The α -*Br deriv.*, dark red with green luster, m. 125–5.5°, crystals with 1 EtOH ; the EtOH -free base, m. 114–5.5°. Oxidation of III in EtOH with AmNO_2 in the presence of dry HCl gives *C-aminodiphenyltetrazolium chloride (V)*, m. 269°; the concd. aq. soln. is not pptd. by NaOAc ; the aq. soln. can be evapd. to dryness without material decompn.; *dichromate*, orange-yellow, decomps. 189° (depending upon rate of heating and size of tube); *dichromate-HCl*, $\text{C}_{26}\text{H}_{26}\text{N}_{10}\text{Cr}_2\text{O}_7\text{Cl}_2$, orange-yellow, m. 175° (decompn.); *chloroplatinate*, pale yellow with bronze luster, m. 249°; *permanganate*, violet-red, decomps. 106–10°; Ag_2O gives a strongly alk. soln. of the free hydroxide. V gives with HCl and NaNO_2 *nitrosoiminodiphenyltetrazolium betaine (VI)*, orange-yellow, m. 177°; *HCl salt*, m. 168°, immediately hydrolyzed by H_2O ; the AgNO_3 salt is pale yellow, decomps. 157–61°; the *chloroaurate*, orange-yellow, m. 119–22°; heating with 2 N HCl gives V. Heating VI in 96% EtOH 3–4 hrs. gives the *iso deriv.*, orange-yellow, m. 154–5°, PhOH and some concd. H_2SO_4 give a carmine-red soln. Heating with HCl for 2 hrs. gives V. V, BzCl and 2 N NaOH give the *benzoyl-C-iminodiphenyltetrazolium betaine*, golden yellow, m. 232°; *HCl salt*, m. 280.5°; *chloroplatinate*, flesh-colored, m. 198° (decompn.); *dichromate*, citron-yellow, m. 170.5°; *permanganate*, violet, explodes at 144.5°. The *Bz deriv.* is fairly stable and heating with $\text{EtOH}-\text{KOH}$ or aq. NaOH for several min. is without effect. Sapon. with 2 N HCl gives V. Reduction of the *Bz deriv.* by H_2S $\text{NH}_3\cdot\text{EtOH}$ gives a *compd.* $\text{C}_{20}\text{H}_{17}\text{M}_6$, m. 222–3°. C. J. WEST

Influence of substituents in the components on the equilibrium in binary solutions. XLVIII. Binary systems of azobenzene with acids. ROBERT KREMANN AND KARL ZECHNER. *Monatsh.* 46, 171–6(1925); cf. *C. A.* 19, 1703—Simple eutectics were formed in binary mixts. of PhN_2Ph with the following acids: BzOH , AcOH , $\text{Cl}_3\text{CHCO}_2\text{H}$, $\text{Cl}_3\text{CCO}_2\text{H}$, cinnamic, salicylic and succinic. Complete temp.-m. p. diagrams are given. XLIX. The binary systems of cinnamaldehyde and salicylaldehyde with phenols. ROBERT KREMANN AND EDUARD ZECHNER. *Ibid* 177–92—The m. p. diagrams for $\text{PhCH}:\text{CHCHO}$ (I) with the 2 naphthols and with $o\text{-NO}_2\text{C}_6\text{H}_4\text{OH}$ could not be produced over the entire concn. range as highly viscous solns. resulted which resisted crystn. With $p\text{-NO}_2\text{C}_6\text{H}_4\text{OH}$, pyrocatechol, and $m\text{-C}_6\text{H}_4(\text{OH})_2$, compds. of 1 mol. I with 1 mol. phenol were observed. With $m\text{-NO}_2\text{C}_6\text{H}_4\text{OH}$ and $m\text{-C}_6\text{H}_4(\text{OH})_2$, compds. of 1 mol. I with 1 mol. phenol were formed. $o\text{-HOC}_6\text{H}_4\text{CHO}$ (II) has less tendency to compd. formation than I. Simple eutectics are given with PhOH , α - and $\beta\text{-C}_{10}\text{H}_7\text{OH}$, 1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$, 1,4- $\text{C}_6\text{H}_4(\text{OH})_2$, $o\text{-NO}_2\text{C}_6\text{H}_4\text{OH}$ and 1,2,4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{OH}$. With picric acid, compds. were formed contg. 1 and 2 mols. of II to 1 of picric acid. L. Binary systems of acids and amines. ROBERT KREMANN, GUSTAVE WEBER AND KARL ZECHNER. *Ibid* 193–224.— BzOH gave simple eutectics with PhNH_2 and α - and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$; with $p\text{-MeC}_6\text{H}_4\text{NH}_2$ compds. contg. 1 and 2 mols. of acid to 1 of amine were formed; with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ the addn. compd. contd. 2 mols. acid to 1 of diamine; with m - and $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ only equimol. compds. were formed. With salicylic acid, equimol. compds. were formed with $p\text{-MeC}_6\text{H}_4\text{NH}_2$, α - and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$, and all 3 isomeric $\text{C}_6\text{H}_4(\text{NH}_2)_2$. Cinnamic acid gave simple eutectics with α - and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$, $p\text{-MeC}_6\text{H}_4\text{NH}_2$, and $m\text{-C}_6\text{H}_4(\text{NH}_2)_2$; with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ an equimol. compd. is formed; with $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ a deep-seated chem. reaction occurs. Succinic acid gave a simple eutectic with $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ and an equimol. compd. with $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$. chem. reaction takes place with o - and $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$. AcOH gave a simple eutectic with α - and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ and with $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$; with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ a compd. of 1 mol. diamine to 2 mols. acid was formed; with $m\text{-C}_6\text{H}_4(\text{NH}_2)_2$, the compd. contd. 1 mol. diamine to 4 mols. acid. For comparison, systems of $\text{CO}(\text{NH}_2)_2$ (I) were studied, and the following compds. with 1 mol. I were detected: 2 mols. AcOH , 1 mol. salicylic acid, with BzOH a liquid compd. was indicated; with succinic acid a secondary reaction, accompanied by loss of NH_3 , took place. T. S. CARSWELL

The photo-oxidation of organic compounds by chromates. I. PLOTNIKOV. Z.

Elektrochem. **32**, 13–5 (1926).—P. is undertaking a general investigation of the subject, using sunlight as the source. This article gives a description of suitable app., and lists of dyes stable and unstable in light in mixed soln. with $K_2Cr_2O_7$. B. H. C.

Mercurization of nitrobenzene and substitution in the benzene nucleus. OTTO DIMROTH. *Ann.* **446**, 148–54 (1925); cf. Holleman, C. A. **17**, 3487.—D. submits a revision of his work on the mercurization of $PhNO_2$ (cf. *Ber.* **35**, 2033 (1902)) which is quoted by H. The *o*-HgCl deriv. is the principal product with about 15% of the *m*-deriv. and a relatively small amt. of the *p*-deriv. A method is given for the detn. of *o*- and *p*- $BrC_6H_4NO_2$ in the presence of the *m*-deriv., which depends upon the fact that $N_2H_4 \cdot H_2O$ reacts with the 1st 2 but not with the *m*-deriv. Since the HgCl compds. can be transformed into Br derivs., this becomes a method for detg. the compn. of a mixt. of these compds. C. J. WEST

Mercuration of aromatic sulfonic acids. Preliminary paper. F. C. WHITMORE AND LOUIS EHRENFELD. *J. Am. Chem. Soc.* **48**, 789–91 (1926).—The mercuration of aromatic SO_3H acids takes place with extreme ease and rapidity, that of the Na salts is a much slower process. *p*- $MeC_6H_4SO_3H$ (190 g.) in 750 cc. H_2O and 35 cc. $AcOH$, treated with 320 g. $Hg(OAc)_2$ in the same amt. of solvent, gave 81 g. of an insol. material, from which no satisfactory product was obtained, and 135 g. of 2-hydroxymercuritoluene-4-sulfonic acid, crystg. with 2 H_2O ; the H_2O is lost over $CaCl_2$, while drying *in vacuo* over P_2O_5 gives the inner salt, $C_7H_5O_3SHg$; the structure was established by replacing the $HgOH$ group by I. C. J. WEST

Identification of phenols by means of the spectroscope. II. H. WALES AND S. PALKIN. *J. Am. Chem. Soc.* **48**, 810–3 (1926); cf. C. A. **18**, 2302; **19**, 2550.—Absorption spectra max. are reported for solns. of azo dye derivs. of 45 phenolic compds. in H_2O , $EtOH$ and Me_2CO . C. J. WEST

Oxidation of arylmagnesium halides. HENRY GILMAN AND AGNES WOOD. *J. Am. Chem. Soc.* **48**, 806–10 (1926).—In a study of the optimal conditions for the prepn. of phenols by the oxidation of arylmagnesium halides it is shown that the yields are strictly limited by the oxidation of Et_2O ; the Et_2O_2 so formed reacts with unaltered $RMgX$ compd. to give a sec. alc. Thus $PhMgBr$ gave 3% of Ph_2 and 18% of $PhMe \cdot CHOH$. The av. yield of $PhOH$ at 0° was 26%; at -5° 29%; at -60° , 21.2%. After refluxing the $PhMgBr$ in Et_2O (without passing O through the soln.) for 8 hrs., the av. yield of $PhOH$ was 6.8%; replacing most of the Et_2O by C_6H_6 gave 16.1% $PhOH$; in $PhMe$ at 108° for 6 hrs., there resulted 21.9% $PhOH$. The rate of the addn. of O appears to have little effect on the yield of $PhOH$. *p*- MeC_6H_4MgBr gave 15.3% *p*- MeC_6H_4OH , 16% (*p*- MeC_6H_4), 11% $PhMe$ and 11% *p*- $MeC_6H_4CHMeOH$. Yellow HgO and $PhMgBr$ in Et_2O - $PhMe$ at 108° for 19 hrs. gave 15.1% $PhOH$; Ag_2O in Et_2O for 10 hrs. gave 18% $PhOH$ and Na_2O_2 in Et_2O for 5 hrs. gave 14.5% $PhOH$. C. J. W.

Orientation in the benzene ring. The bromination of pyrogallol 2,6-dimethyl ether. A. A. LEVINE. *J. Am. Chem. Soc.* **48**, 797–800 (1926).—2,6-(MeO) $_2C_6H_2OH$ and Br in CS_2 give 80% of 3-bromopyrogallol 2,6-di-Me ether (I), b_{40} 185 – 90° ; oxidation with Cr_2O_3 in 50% $AcOH$ gives 90% of 3,3'-dibromo-2,6,2',6'-tetramethoxybiphenone (dibromocedriret), gray, m. 254° , which is reduced by SO_2 in moist Me_2CO to dibromohydrocedriret, m. 262° (Hayduck, *Ber.* **9**, 929 (1876)); and 5% of 3-bromo-2,6-dimethoxy-*p*-benzoquinone (II), reddish yellow, m. 148° . Chlorination of I in CS_2 gives 85% of the 4,5-di-Cl deriv., m. 127 – 8° ; *Bz* deriv., m. 114 – 5° ; *Ac* deriv., m. 97 – 8° . Oxidation gave 45% of the 5-Cl deriv. of II, red, m. 164 – 5° , also obtained by chlorinating II. 2-Bromosyringic acid, m. 155° (95% yield), on oxidation with Cr_2O_3 in H_2SO_4 gives 62% of II. The combined orienting effect of the 2 MeO groups is thus greater than that of the HO group. C. J. WEST

Preparation of some alkyl and aryl derivatives of phloroglucinol. EMIL KLARMANN AND WM. FIGDOR. *J. Am. Chem. Soc.* **48**, 803–5 (1926).—*n*-Phlorocaprophenone, m. 118° (air-dry, 95°); reduction with amalgamated Zn and 5% HCl gives 70% of hexylphloroglucinol, m. 108° . 2,4,6-Trihydroxydiphenylmethane, oily (50% yield). 2,4,6-Trihydroxydiphenylethane, m. 159 – 60° ; $FeCl_3$ gives a pink ppt.; yield, 65%. $AcCl$ gives a mixt. of the di-*Ac* deriv., m. 135 – 6° (gives a brown ppt. with $FeCl_3$), and a tri-*Ac* deriv., heavy oil. These derivs. are highly germicidal to *B. typhosus*, the $PhOH$ coeff. being about 8. C. J. WEST

Fungi dyestuffs. V. Constitution of polyporic acid. FRITZ KÜGL. *Ann.* **447**, 78–85 (1926); cf. C. A. **20**, 406.—The polyporic acid of Stahlschmidt (*Ann.* **187**, 177; **195**, 365) is 3,6-dihydroxy-2,5-diphenyl-1,4-benzoquinone, m. 118° , which makes up 18% of the wt. of *Polyporus nidulans* Fr.; the di-*Ac* deriv. m. 209° ; di-Me ether, m. 192° ; a micro Zn distn. gives terphenyl, m. 206 – 7° ; oxidation with Cr_2O_3 gives only $PhOH$; a crystallographic comparison is also given. C. J. WEST

The preparation of saccharin. P. DUROCHER. *La nature* 53, ii, 361-4(1925).—An illustrated description of large-scale production, including the chemistry involved.

C. C. DAVIS

Remarks concerning the work of Ernst Waser. Phenylalanine series. VI. Decarboxylation of tyrosine and leucine. GÉZA ZEMPLÉN. *Helvetica Chim. Acta* 9, 115(1926).—A polemic (cf. Waser, *C. A.* 20, 1067).

REYNOLD C. FUSON

The catalytic reduction of several acid chlorides. FRITZ ZETZSCHE, CHRISTIAN FLÜTSCH, FLORIAN ENDERLIN AND ALFRED LOOSLI. *Helvetica Chim. Acta* 9, 182-5 (1926); cf. *C. A.* 16, 865; 20, 380.—Reduction of batches of 2 g. sym. *o*-C₆H₄(COCl)₂ (I) in tetralin with 1 g. 2.5% Pd-kieselguhr catalyst at 150° and with increasing amts. of regulator (2.5-25 mg. quinoline S) showed a very slight sp. influence of the regulator and it is believed that a combination with I occurs, thus poisoning the system. After filtering off the catalyst, washing it with Et₂O, shaking the filtrate with NaHSO₃, standing a day, then treating with NaOAc, AcOH and PhN₂H₃, phenyl-1-hydroxyphthalazine is obtained; the residue from the Et₂O on evapn. *in vacuo* was extd. with H₂O from which the *phthalide* was obtained; repeated extn. of the catalyst with hot glacial AcOH yields *bipthalide*, m. 332°. Attempts to reduce benzyl-, methylbenzyl- and diethylmalonyl chlorides to the malonic dialdehydes were not successful although reduction occurred below 100°, yielding oils with no aldehydic properties. Almost equally unfruitful were the attempts to prep. dialdehydes of pyridinecarboxylic acids and this is believed to be due to the fact that acid chlorides of lutidine- (II) and collidinedicarboxylic acids (III) can only be obtained as double compds. with POCl₃, the latter poisoning the aldehyde regulators. Use of SOCl₂ gave resinous products. Dry II in CHCl₃ with PCl₅ forms a compd., m. 200-30°, which is probably the *acid chloride-POCl₃ double compd.* and is pptd. from soln. with ligroin; when treated with PhNH₂ in EtOH, pptd. with H₂O and recrystd. from dil. alc. it yields the *anilide*, m. 278-81° (decompn.). Similarly from III the *acid chloride-POCl₃ double compd.* (IV), m. 125-32° and the *anilide*, m. 288-90°, were obtained. Reduction of IV in xylene or in BzOH gave 15% of *aldehyde* isolated as the *diphenylhydrazone*, yellow, m. 146-9° (decompn.). Heating of β,α-C₁₀H₆(OH)CO₂H with Ac₂O and 3 drops H₂SO₄ below 80° for 0.5 hr., pouring into H₂O and crystg. from H₂O the oil which solidifies on standing gave *2-acetoxynaphthalene-1-carboxylic acid*, m. 130.5-15°; in CHCl₃ with PCl₅ this gave the *acid chloride*, m. 140-1°.

N. A. LANGE

The constitution of chlorinated derivatives. A. CORNILLOT. *Compt. rend.* 181, 1071-3(1925).—When the compds. obtained by chlorination of phthalonic acid derivs. (cf. *C. A.* 18, 1281; 19, 265) are treated with C₆H₆ and AlCl₃ under suitable conditions, a previously unknown series of compds. is formed. With Et phthalonate the best results are obtained by mixing the Et ester of the phthalonic acid deriv. with 4.5 times its wt. of C₆H₆, adding the AlCl₃ progressively and then extg. the resin for a long time with dil. HCl. On agitating the C₆H₆ soln. with NaHCO₃ soln. a small amt. of *benzhydrol-o-carboxylic acid*, *o*-HO₂CC₆H₄CH(OH)Ph, is pptd., leaving in soln. *Et α-phenylphthalidecarboxylate*, O.CO.C₆H₄ CPhCO₂Et, m. 70°, the constitution of which was

proved by its inability to form a semicarbazide, and its decompn. by alkalis or acids to EtOH, CO₂ and α-phenylphthalide. These reactions show that the phthalonic ester has the formula already attributed to it and that the substitution of Ph for Cl weakens considerably the bond between the CO₂H group and the side chain. C. C. D.

Bisphthalidecarboxylic esters. ANDRÉ CORNILLOT. *Compt. rend.* 182, 142-3 (1926).—In continuation of work on the substitution of Cl in chlorophthalidecarboxylates by other groups (cf. preceding abstr.) the action of organo-Zn compds. was studied. The latter bring about a union of 2 mols. thus: 2 C₆H₄.CO.O.C(CO₂Et)Cl →

C₆H₄.CO.O.C(CO₂Et)C(CO₂Et).O.CO.C₆H₄. This new *compd.* should have 2

optically inactive isomers, in agreement with which it was found that MeZnI or MeZnBr and C₆H₄.CO.O.C(CO₂Et)Cl gave 2 *products* of identical compn., cryoscopic prop-

erties, etc. One was composed of short needles, m. 188°, the other of elongated needles, m. 159°, about twice as much of the 2nd being formed as of the 1st. They are decompd. by alkalis to form a mixt. of phthalonic and phthalidecarboxylic acids. A mixt. of the 2 isomers can also be obtained by boiling C₆H₄.CO.O.C(CO₂Et)Cl in

alc. with reduced Ag.

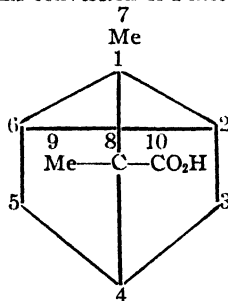

C. C. DAVIS

Higher terpene compounds. XXVII. Azulene. L. RUZICKA AND E. A. RUDOLPH.

Helvetica Chim. Acta 9, 118-40(1926); cf. *C. A.* 20, 421.—The high-boiling fraction (110–70° at 12 mm.) of yarrow oil was treated with H_3PO_4 and by exn. with petroleum ether a H_3PO_4 addn. compd. of *chamazulene* (I) resulted. Decompn. with H_2O yielded crude I which was converted into its *picrate* (II), m. 115° (from EtOH or MeOH). On treatment with 5% NaOH II gave pure I (yield 1.6%), b_{12} 161°, d_4^{20} 0.9883; *styphnate*, m. 95–6° (from EtOH or MeOH). Camomile oil treated similarly gave I (4.6% yield). Similarly, from the dehydrogenation products of the sesquiterpene hydrocarbons from eucalyptus oil was obtained *eucazulene* (2.4% yield based on the amt. of sesquiterpenes used), $b_{0.5}$ 135°; *picrate* (from EtOH), m. 118–20°; *styphnate* (from EtOH or MeOH), m. 122–3°. From the dehydrogenation product of *guaiane* (III) was obtained in the same way *guaiazulene* (IV) (12% yield based on guaial or 20% based on III), b_{11} 164°, d_4^{18} 0.9759; *picrate*, black needles, m. 122°; *styphnate*, black needles (from MeOH), m. 105–6°. Oxidation of I with $KMnO_4$ failed to give either Me_2CO or a phthalic acid. Reduction of I with Na in moist Et_2O or in EtOH destroyed the blue color, yielding a greenish oil; in AmOH Na gave a greenish oil, b_{11} 118–24°, d_4^{20} 0.9177, n_D^{20} 1.5200. This analyzed approx. for *hexahydrochamazulene* (V). *Octahydrochamazulene* (VI), b_{11} 119°, resulted when I was reduced catalytically with Pt black at 0.1 atm. in EtOAc. V and VI when heated with S gave I. II reduced similarly with Pt black gave *octahydroguaiazulene* (VII), b_{11} 123–5°, d_4^{20} 0.8872, n_D^{20} 1.4834. VII heated with S gave IV. III reduced with Pt black gave *dihydroguaiane*, b_{15} 124–5°, d_4^{20} 0.8955, n_D^{20} 1.4894.

REYNOLD C. FUSON

Constitution of teresantallic acid. I. RUZICKA AND FR. LIEBL. *Helvetica Chim. Acta* 9, 140-4(1926).—The aldehyde of *teresantallic acid* (I) yields a *semicarbazone*, m. 217°, which on reduction (in a closed tube at 180°) with Na in EtOH yields *tricyclene* (II) which is converted into isoborneol (III) and finally into camphor (IV). Since in the formation of III from II the OH group is attached to C atom 2, this atom must be a part of the labile ring of I. This conversion of I into IV is, therefore, a strong argument in favor of the structure

R. C. F.

Esters of camphylcarbinol. II. RUPE AND (MISS) M. SCHAEFER. *Helvetica Chim. Acta* 8, 853-65(1925).—Camphylcarbinol (I), prepd. by reduction of methylene-camphor (II), was esterified with various acid halides in C_6H_5N . Letting stand overnight, heating 1-3 hrs. on the H_2O bath, treating cold with dil. HCl, shaking out with Et_2O and washing with dil. HCl, dil. aq. NaOH, and finally $KHSO_4$ soln., drying over $MgSO_4$, removing the Et_2O , finally at 40–50° in *vacuo*, and then distg. in a high vacuum maintained by a good Hg pump. The esters decomp. to some extent on distn. in an ordinary vacuum into II and the acid. Even at the low pressures reached, at which the b. ps. given below were measured, a trace of decompn. occurred, becoming appreciable in the

case of the sorbic ester. It was expected that in the reaction $C_8H_{14} \begin{matrix} \diagup C:CHOH \\ \diagdown CO \end{matrix} \rightarrow$

$C_8H_{14} \begin{matrix} \diagup CHCH_2OH \\ \diagdown CO \end{matrix}$ 2 optical isomers would result, but the I behaved as if homogeneous, and only in the case of the isobutyrate were 2 forms observed. **Esters of camphylcarbinol:** Formate, acetate (Akermann, *Diss.*, Basel, 1919). **Propionate** (III), by using $EtCOBr$, b. (see above) 63°, m. 28–36°, $[\alpha]_D^{20}$ 41.52°, $[\alpha]_D^{20}$ 55.37°, $[\alpha]_{Hg}^{20}$ 68.69°, $[\alpha]_D^{20}$ 99.26°, d_4^{20} 1.0430; in another prepn. d_4^{20} 1.0420, $[\alpha]_D^{20}$ 54.75°. **Isobutyrate**, b. 61°, crystd. partially after several weeks, the *solid isomer* (IV), m. 31.5–3.0°, $[\alpha]_D^{20}$ 23.48°

in PhH, the liquid portion (V) showing $[\alpha]_D^{20}$ 36.85° in PhH (10% solns.). *Butyrate*, b. 73°, d_4^{20} 1.0254, $[\alpha]_D^{20}$ 53.45°. *Valerate*, b. 82°, d_4^{20} 1.0140, $[\alpha]_D^{20}$ 49.18°. *Hexahydrobenzoate*, b. 95°, d_4^{20} 1.0507, $[\alpha]_D^{20}$ 49.49°. *Phenylacetate*, b. 120°, d_4^{20} 1.0902, $[\alpha]_D^{20}$ 40.94°. *Hydrocinnamate*, b. 141°, d_4^{20} 1.0791, $[\alpha]_D^{20}$ 38.56°. *Cinnamate*, thick oil, b. 145°, d_4^{20} 1.1004, $[\alpha]_D^{20}$ 46.06°. *Crotonate* (VI), b. 79°, d_4^{20} 1.0506, $[\alpha]_D^{20}$ 56.5°. *Sorbate*, yellow, b. 99°, d_4^{20} 1.0433, $[\alpha]_D^{20}$ 54.55°, changes in several days to a resin. In the prepn. of VI it was found necessary to oxidize MeCH:CHCHO to the acid with O₂ in order to obtain it free from halogen (Duchesne and Delépine, C. A. 19, 634); the Na salt with PCl₅ under Et₂O gave the chloride, b. 120°, but even with these precautions VI contained 0.37% Cl. Na sorbate was converted into the chloride in the same way. Tables of data for the different wave lengths are given and the rotatory dispersions shown to be quite normal, mean values for the esters being: $[\alpha]_F/[\alpha]_D$ 2.36, λ_D 591.5, λ_D^0 0.09271, P. R. D., 189.06, values very close to those for derivs. of II. When $1/\alpha$ is plotted against λ^2 for III, IV and V (Lowry and Dixon), the curves are not entirely straight lines, possibly because of the presence of several asym. C atoms, which might make the exptl. curve the resultant of two others. Other previously observed regularities are also pointed out.

M. HEIDELBERGER

Action of nitrogen tetroxide on caoutchouc. FRIEDRICH EMDEN. *Ber.* 58B, 2522-7 (1925).—This work was undertaken to det. whether Weber's "dinitrocaoutchouc," C₁₀H₁₆O₄N₂ (I) (*Ber.* 35, 1947 (1902)), is really capable of existence, and, if not, what the primary product of the action of N₂O₄ (E. worked around 0°, i. e., at temps. at which N₂O₄ is practically not at all dissociated into NO₂) is. The crude caoutchouc was carefully purified, the N₂O₄ was not passed directly into the caoutchouc soln. but previously dissolved to satn. in CCl₄ at room temp., the reaction was carried out at a low temp. under such conditions (caoutchouc soln. slowly added to the N₂O₄ soln. that from the 1st instant of reaction the N₂O₄ was present in considerable excess, and the action was not continued more than 2 hrs. at most. In this way was obtained a pure white product very sensitive to heat, sinters 90-5° (incipient decompn.), reduces hot Fehling soln., does not dissolve in aq. NH₄OH even after several days but gradually dissolves in dil. aq. NaOH. When covered with Me₂CO it is at first insol. but after several days (a few hrs. if warmed) it dissolves without a residue to a clear red-brown soln., from which it can be reprecip. by H₂O but in a slightly yellowish form which is now easily sol. in Me₂CO at room temp.; the soln. in hot Me₂CO is not accompanied by liberation of CO₂ or other gases; the Me₂CO-sol. form is the more stable. The products obtained from *Ilex* caoutchouc and from guayule do not differ from each other and have a remarkably const. compn., even though the conditions of prepn. varied widely (temp. from -15° to 4°, length of reaction from 10 to 90 min.). The av. C, H and N content (46.45, 6.04, 10.78%) agrees remarkably well with that calcd. for C₁₀H₁₆O₄N₂ (II); the yields (which varied but little under different conditions) also agreed well with the calcd. I is, therefore, probably not capable of existence; the addn. of N₂O₄ to caoutchouc is accompanied by an oxidation and the *nitrosate* II may be regarded as the primary product of the reaction. If allowed to stand 24 hrs. at room temp. with an excess of N₂O₄ soln. the II becomes easily sol. in Me₂CO and in dil. NH₄OH and NaOH and when refluxed in Me₂CO now evolves 0.1 mol. CO₂.

C. A. R.

Superheating of homogeneous organic compounds. II. Experiments with mono- and diketones. SIEGFRIED SKRAUP AND SIEGFRIED GUGGENHEIMER. *Ber.* 58B, 2488-2500 (1925); cf. C. A. 19, 266.—Aliphatic-aromatic ketones are considerably more stable towards high temps. than the corresponding hydrocarbons, the compds. *p*-MeOC₆H₄COR being stable up to 360° where R = Et, Pr and iso-Pr and up to about 340° where R = Me. Only at very high temps. are they attacked, with loss of H₂O and autocondensation, followed by the rapid formation of resinification and carbonization products in which no simpler org. split products can be detected. Replacement of Ph in diketones by *p*-ClC₆H₄ results in increased sensitiveness to temp. but a decreased tendency in the products to undergo secondary reactions. Study of diketones of the type ArCO(CH₂)_nCOAr (*n* = 2 to 5) showed that, as with paraffin chains, those with an even no. of C atoms are distinctly more reactive than those with an odd no. The 1,4-, 1,6- and 1,7-diketones suffer a loss of H₂O essentially similar to that produced by condensation agents; the sensitiveness to temp. and to dehydrating agents runs closely parallel. From *p*-MeOC₆H₄COMe (phenylhydrazone, m. 142°, decomp. on long standing) heated 15 hrs. at 320-30°, 70% is recovered unchanged; after 24 hrs. at 325-35° and 2 hrs. at 350°, 60%; after 50 hrs. at 310°, 70-80%. After 20 hrs. at 360-80°, some combustible gas was obtained on opening the tube, the contents of which

consisted of H_2O , a few oily drops and a completely carbonized mass from which a few drops of the unchanged ketone were isolated by vacuum distn.; 72 hrs. heating at $340-50^\circ$ gave similar results. Of $p\text{-MeOC}_6\text{H}_4\text{COEt}$ (obtained in 73% yield from 1 mol. each of EtCOCl and PhOME with 1 mol. AlCl_3 in PhNO_2 at room temp.), 85% is recovered unchanged after 15 hrs. at $320-30^\circ$, 80% after 50 hrs. at $330-40^\circ$, 60% (together with a small amt. of a substance, $b_{11} 190^\circ$, m. $135-40^\circ$) after 45 hrs. at $340-60^\circ$; 100 hrs. heating at $360-80^\circ$ resulted in complete carbonization. From $p\text{-MeOC}_6\text{H}_4\text{COPr}$ heated 20 hrs. at $300-10^\circ$, 92% is recovered unchanged; after 18 hrs. at 360° , 80%; 100 hrs. heating at $360-80^\circ$ results in almost complete carbonization but a small amt. of the ketone can still be isolated as the phenylhydrazone. Of $p\text{-MeOC}_6\text{H}_4\text{COCHMe}_2$, 86% is unchanged after heating 15 hrs. at 360° . $(\text{CH}_2\text{Bz})_2$, heated 18 hrs. at $300-10^\circ$, gave 80% α, α' -diphenylfuran, m. 88° . $\text{CH}_2(\text{CH}_2\text{Bz})_2$, m. 65° (obtained in 65% yield by sapon. of $\text{CH}_2(\text{CHBzCO}_2\text{Et})_2$, m. $87-8^\circ$, which, in turn was obtained in 97% yield from $\text{BzCH}_2\text{CO}_2\text{Et}$), after 20 hrs. at $320-30^\circ$ gave 20% unchanged diketone, PhCOMe and a dark viscous oil (presumably condensation products of PhCOMe and $\text{CH}_3\text{:CH-COPh}$). *Di-p-chlorobenzoylpropane*, obtained in poor yield from $\text{CH}_2(\text{CH}_2\text{COCl})_2$ and C_6H_6 , m. 117° ; like $\text{CH}_2(\text{CH}_2\text{Bz})_2$ it is unchanged by heating 5 min. on the H_2O bath with concd. H_2SO_4 ; likewise it can be almost completely recovered after heating 4 hrs. alone at 302° , and when heated 22 hrs. at $325-35^\circ$ in a small flask in a slow current of N it yields only a trace of an oil having an PhCOMe odor and yielding a phenylhydrazone, m. 110° . $(\text{CH}_2\text{CH}_2\text{Bz})_2$ (4 g.) heated 20 hrs. at $300-10^\circ$, gave 0.6 g. unchanged diketone and 1.5 g. of viscous yellow oil, $b_{14} 200-25^\circ$, yielding with ether-petroleum ether a small amt. of crystals, m. 90° , behaving towards Br in CS_2 and towards KMnO_4 in Me_2CO like benzoylphenylcyclopentene (Bauer, C. A. 8, 3181); 2 hrs. heating at 340° gave only an ill-defined polymerization product and short heating on the H_2O bath with concd. H_2SO_4 resulted in oxidation to BzOH . *Di-p-chlorobenzoylbutane* (I) (obtained in 75% yield from 10 g. $(\text{CH}_2\text{CH}_2\text{COCl})_2$, 100 g. PhCl and 14 g. AlCl_3 at $50-5^\circ$), m. $166-7^\circ$; at the same time is formed 13% of δ -*p-chlorobenzoylvaleric acid* (II), m. 130° . With 20 g. AlCl_3 (which had largely fallen to a powder in the stock bottle) in 130 g. PhCl at 50° , then at 60° and 80° and finally a few min. at 90° , 12 g. of the chloride gave 20% I, 28% II and chlorophenylchlorobenzoylcyclopentene (III), m. 130° (with coarsely granular AlCl_3 quickly pulverized before use, the yields of I and II were 65 and 20%, resp.); III, however, cannot be obtained from preformed I with AlCl_3 in PhCl . Heated on the H_2O bath with 2 cc. concd. H_2SO_4 until dissolved and allowed to stand overnight, 0.5 g. I gives 0.1 g. of the isomer (IV), m. 108° , of III. From 5 g. I heated alone 24 hrs. at $255-65^\circ$ are obtained 0.2-0.3 g. unchanged I, less than 0.1 g. $p\text{-ClC}_6\text{H}_4\text{CO}_2\text{H}$, 0.7 g. IV, 1.3 g. of a mixt. of III and IV and 1 g. of polymerization products; 50 hrs. heating at $320-30^\circ$ or 45 hrs. at 280° gives chiefly polymerization products, accompanied by carbonization and formation of $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$; $\text{CH}_2(\text{CH}_2\text{CH}_2\text{Bz})_2$ is unchanged by cold concd. H_2SO_4 and oxidized to BzOH on heating, heated 28 hrs. at $325-30^\circ$ it gives small amts. of Bauer's isomeric cyclohexene derivs. m. $75-80^\circ$ and 110° ; 8 hrs. heating at 340° results largely in resinification. *Di-p-chlorobenzoylpentane*, m. 112° , is obtained in 75% yield, together with 23% ϵ -*p-chlorobenzoylcaproic acid*, m. $139-40^\circ$, from $\text{CH}_2(\text{CH}_2\text{CH}_2\text{COCl})_2$, PhCl and AlCl_3 ; it is not attacked by H_2SO_4 at 100° , while 6 g. heated 13 hrs. at $285-95^\circ$ gives a little $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$, 0.1 g. of yellowish needles, $\text{C}_{13}\text{H}_{16}\text{OCl}_2$, m. 156° , and a dark viscous oil.

C. A. R.

Beckmann rearrangement. VI. Configuration of benzophenone, acetophenone and benzaldoximes. JAKOB MEISENHEIMER, PAUL ZIMMERMANN and UDO V. KUMMER. *Ann.* 446, 205-28 (1925); cf. C. A. 19, 2819.—2-Bromo-3,5-dinitrobenzoic acid, pale yellow, m. 213° , results in 86% yield from $o\text{-BrC}_6\text{H}_4\text{CO}_2\text{H}$ in concd. H_2SO_4 and 5 mols. KNO_3 at 50° , and a final temp. of $130-40^\circ$. Transformed into the acid chloride by PCl_5 and treated with C_6H_6 and AlCl_3 there results 97% of 2-bromo-3,5-dinitrobenzophenone, pale yellow, m. $153-4^\circ$. With NH_2OH this does not yield an oxime but gives at once 98% of 2-phenyl-4,6-dinitroindoxazene (I), orange-yellow, m. $242-3^\circ$ (decompn.), probably identical with the product of Cathcart and Meyer (*Ber.* 25, 3296 (1892)). In EtOH-KOH this yields the K salt of 2-hydroxy-3,5-dinitrobenzophenone, red, decomp. $180-200^\circ$; in H_2O it gives I. I is not changed by heating with 4 parts concd. H_2SO_4 for 12 hrs. 2,3,5- $\text{Cl}(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{Bz}$ and 2,3,5- $\text{MeO}(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{Bz}$ with NH_2OH likewise give I. 2-Chloro-5-nitrobenzophenone oxime (II), pale yellow, m. 180° , results nearly quant. by heating the ketone, $\text{NH}_2\text{OH} \cdot \text{HCl}$ and EtOH at $140-50^\circ$ for 2.5 hrs. Soln. in dil. NaOH gives 2-phenyl-4-nitroindoxazene (III), pale yellow, m. 143° . Beckmann rearrangement of II with PCl_5 in Et_2O gives 63% of 2-chloro-5-nitrobenzamidide, m. 158° , identical with a synthetic product from 2,5- $\text{Cl}(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{COCl}$ and PhNH_2 ; there is

also formed a *compd.* $C_{13}H_{10}O_6N_2ClP \cdot H_2O$, m. 136–8°. *2-Bromo-5-nitrobenzophenone*, pale brown, m. 121°; *oxime*, pale yellow, m. 195–6°. With dil. alkali it gives **III**. Beckmann rearrangement gives 77% of 2,5-Br(O₂N)C₆H₃NHAc, m. 168–9°, and 14% of the *compd.* $C_{13}H_{10}O_6N_2BrP$, m. 135–9°. *2-Methoxy-5-nitrobenzophenone*, pale yellow, m. 129°, in 82% yield from the Cl deriv. and MeONa; *oxime*, m. 195°. Concd. KOH gives 94% **III**. The Beckmann rearrangement gave *2-methoxy-5-nitrobenzanilide*, m. 194°, identical with the synthetical product which results in 95% yield from the Cl deriv. and MeONa. 2-BrC₆H₄Ac, b₁₁ 113–4°, on nitration at –1° to –3° with fuming HNO₃, gives 93% of *2-bromo-5-nitroacetophenone* (IV), m. 88–9°, which gives with Br in AcOH 90% of *2,ω-dibromo-5-nitroacetophenone*, m. 66–7°. NH₂OH in AcOH gives *N-di-[2-bromo-5-nitrophenacyl]hydroxylamine dioxime*, crystg. with 1 EtOH, m. 167–75°, after drying, 195° (decompn.); in HCl other products result which are being investigated. IV *oxime*, m. 171° (α-form) and 132° (β-form); the β-form is the more sol. in all solvents; soln. of the β-form in EtOH contg. a little H₂O gives the α-form; the same change occurs on melting the β-form. Both forms (the β-form more readily) yield *2-methyl-4-nitroindoxazene* (V), m. 129°; boiling EtOH-KOH gives a *compd.*, m. 165°, probably *2-hydroxy-5-nitroacetophenone oxime*. Since the β-form gives V in the cold, the α-form only on boiling, the formation of V is a suitable method of detg. the content of the 2 forms in a mixt. The Beckmann rearrangement of the α-form with PCl₅ gives 2,5-Br(O₂N)C₆H₃NHAc; the mixt. of the 2 forms with concd. H₂SO₄ (0.5 hr. at 100°) gives 50% of 2,5-Br(O₂N)C₆H₃NH₂, no other rearrangement product was observed. Attempts to prep. a di-NO₂ deriv. of 2-BrC₆H₄Ac gave only 2,5-Br(O₂N)C₆H₃CO₂H. α-2,5-Cl(O₂N)C₆H₃CH₂NOH and PCl₅ in abs. Et₂O give nearly quant. 2,5-Cl(O₂N)C₆H₃CN, m. 105–6°. With Na₂CO₃ in dil. EtOH there results 2,5-HO(O₂N)C₆H₃CN, m. 197°, whose Na salt forms yellow needles. Heating the nitrile above its m. p. gives a *polymer*, yellow, does not m. 250°, changed by NaOH to a red powder. Since the usual methods of prep. the β-oxime failed, it was prep. as follows: *2-Chloro-5-nitrobenzyl chloride*, m. 66° (35% yield from *o*-ClC₆H₄CH₂Cl and fuming HNO₃ at 30–40°); NH₂OH gives *N-di-[2-chloro-5-nitrobenzyl]hydroxylamine*, m. 225°, unchanged by boiling CrO₃ in AcOH or by KMnO₄ in Me₂CO; fuming HCl at 150° is also without action. The product obtained according to Brady and Bishop (C. A. 19, 2650), crystd. from C₆H₆, gives 20–5% of the β-oxime, yellow, m. 176°, on melting the β-form is changed largely into the α-form. *2-Hydroxy-5-nitrobenzal dioxime*, m. 225° (80% yield); it is unchanged after boiling 3 hrs. with acid. *Propionyl-α-benzil monoxime*, m. 70°; 10% NaOH at room temp. gives nearly quant. the decompn. products, BzOH and PhCN. *Cinnamoyl-α-benzil monoxime*, m. 117°. C. J. W.

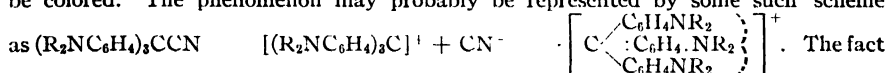

Preparation of 2,4-dihydroxydiphenylmethane and of 2,4-dihydroxydiphenylethane
 EMIL KLARMANN. *J. Am. Chem. Soc.* **48**, 791–4 (1926) — *2,4-Dihydroxydiphenyl methane*, m. 76–7°, b₁₂ 210–5°, results in 50% yields from *m*-C₆H₄(OH)₂, PhCH₂Cl and AlCl₃ in PhNO₂ and in 30% yields by reducing the corresponding ketone with amalgamated Zn and 1.3 HCl. *2,4-Dihydroxydiphenylethane*, m. 131°, results in 70% yields by reducing *m*-dihydroxydesoxybenzoin, m. 121°. Both *compds.* show a high germicidal action, the PhOH coeff. being 22 and 40, resp. The corresponding *p*-HOCH₂CH₂Ph is only 4.6 times stronger than PhOH. C. J. WEST

Coupling reaction of the Grignard reagent. I. The *o*- and *p*-cyanobenzyl halides.
 R. C. FUSON. *J. Am. Chem. Soc.* **48**, 830–6 (1926). — *p*-NCC₆H₄CH₂Br or *p*-NCC₆H₄CH₂I and EtMgI give amorphous products which contain halogen but no N. *o*-NCC₆H₄CH₂Br, b₄ 124°, m. 71.5–2.5°, and EtMgI give 42.5% *s*-bis-[*o*-cyanophenyl]ethane (I), m. 138.5–9.5°; *o*-NCC₆H₄CH₂I, m. 76.5–78.5° (97% yield from the bromide and NaI), and EtMgBr give 25% of the same coupling product. MeMgI may replace the EtMgBr with about the same yield. EtOH-KOH and I give 70% of *s*-bis-[*o*-amino phenyl]ethane, m. 241–2°, while further heating (38 hrs.) gives 50% of *s*-bis-[*o*-carboxy phenyl]ethane, m. 226–8°. C. J. WEST

Triphenylmethane group. HAKON LUND. Univ. Copenhagen, *Diss.* 1926, 7–102. — When MeO groups are introduced in the *p*- and *o*-positions in the C₆H₅ rings of Ph₃COH, *compds.* are produced that react with increasing readiness with H⁺ to form water and the substituted cation Ph₃C⁺. The change from Ph₃COH, which is almost entirely unionized in concd. HCl, to its hepta-MeO deriv., which is highly ionized in aq. HCN, is gradual. In the solid state the normal carbinyl chlorides are colorless when the no. of substituents is less than 4 and colored when the tetra- or higher MeO derivs. are produced. The latter are salts, almost completely dissociated in Me₂CO as well as in H₂O. Some of the highly substituted carbinols may be used as indicators, being colorless in basic and colored in acid solns. L. believes that the rearrangement of the triarylmethyl group from the alkyl to the ionic form does not involve a special orientation of the

MeO groups, that the quinonoid structure idea of color should be modified, and that the oxonium theory has no foundation whatever. E. O. ELLINGSON

Photochemical rearrangements in the triphenylmethane series. III. J. LIFSCHITZ. *Ber.* 58B, 2434–40(1925); cf. *C. A.* 15, 2282. It was shown in the earlier papers that derivs. of di- and triaminotriphenylmethanes rearrange, on exposure to light of short wave length, into the isomeric dye salts from which they are formed spontaneously in the dark. Similar phenomena have been observed not only with *p,p'*-(HO)₂ derivs. (benzaurin (I)), but also with derivs. in which the Ph residues are not substituted. Thus, I, converted into the colorless carbinol or cyanide by treatment with excess of alkali or KCN, resp., again assumes its characteristic color on illumination, and the same is true of phenolphthalein (II) and the unusually stable Ph₃CCN (III), Ph₃CSO₃H (IV) and Ph₃CSCN (V) give with ultra-violet light either salt-like isomers or Ph₃COH and the corresponding acid; in none of these cases is any color produced as the result of the illumination itself. III and V, when pure, are absolute non-electrolytes; perfectly pure, carbinol-free III gives with AcOH·H₂SO₄ or pure concd. H₂SO₄ no trace of color, and V in CHCl₃ c.: in freshly prepd. cold alc. soln. gives no SCN⁻ reaction; carbonium properties appear in III only after illumination, SCN⁻ reactions in V after illumination, heating or standing in soln. Ph₃CH derivs. can, therefore, exist in a non-electrolyte and an electrolyte form and the latter need by no means be colored. The phenomenon may probably be represented by some such scheme

that perfectly colorless solns. of certain Ph₃CH derivs. show strong ionic reactions and considerable elec. cond. supports the mol. compd. theory of Pfeiffer (elaborated by L., *C. A.* 19, 820, and earlier papers) to explain the phenomena of halochromism as against the isomerism theory (cf. Hantzsch, *C. A.* 16, 1414). The decolorization of I by alkalis (Meyer and Gerloff, *C. A.* 18, 2889) proceeds the more rapidly the greater the concn. of the alkali; alc. hinders the reaction; the rapidity of the restoration of the color in uviole or quartz by Hg light increases with increase in diln. of the soln. and decrease in the degree of alky. III, freed from the last traces of carbinol by shaking in C₆H₆ with concd. H₂SO₄, forms in H₂SO₄ and AcOH colorless solns. which, however, gradually become more and more intensely yellow on illumination, but the solns. in pure C₆H₆ and AcOH remain colorless during the illumination and become yellow only on subsequent addn. of H₂SO₄; analogous solns. kept in the dark do not assume this characteristic color even on heating. IV and its Na salt in H₂O rapidly deposit Ph₃COH on illumination. The freshly prepd., perfectly colorless solns. of V in cold MeCN (distd. from P₂O₅) have a mol. cond. of 1.37, 2.395 and 3.838 for *V* = 50.37, 100.73 and 201.46, resp., at 25.1°; in well-stoppered flasks they remain colorless for weeks, and the cond. increases only slightly. From all of its solns., whether or not they already show SCN⁻ reactions, the V crystals unchanged. The golden yellow solns. of Ph₃CN:NPh are decolorized quite rapidly when exposed to light of short wave length. C. A. R.

Formation of triphenylmethyl in the ethyl acetoacetate synthesis. F. F. BLICKE. *J. Am. Chem. Soc.* 48, 738–9(1926).—Ph₃CB₃ and the Na deriv. of AcCH₂CO₂Et in Et₂O–C₆H₆ react to form Ph₃C (isolated as the peroxide) and Ph₃CCH₂CO₂H, m. 177–8°. C. J. WEST

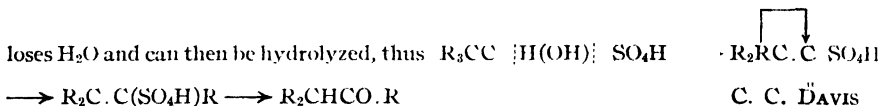

2-(2-Hydroxy-3-methylbenzoyl)-3,4,5,6-tetrachlorobenzoic acid, iso-*o*-cresol-tetrachlorophthalein and some of their derivatives. W. R. ORNDORFF and CARLSLE SCHADE. *J. Am. Chem. Soc.* 48, 769–73(1926).—2-(2-Hydroxy-3-methylbenzoyl)-3,4,5,6-tetrachlorobenzoic acid (I), m. 219–20°, from *o*-MeC₆H₄OH and Cl₄C₆(CO)₂O; diacetate, m. 182°; in some expts. there resulted an anhydride, m. 242.5°, which, however, does not give I with alkalis; Zn salt, light yellow with 3 H₂O, increasing in color when anhyd. Ba salt, with 9.5 H₂O. When I is heated with 7% aq. NaOH, there results 4-methyl-5,6,7-trichloro-8-xanthonecarboxylic acid, m. 286–9°; Na salt; acetate, m. 275–80°. With *o*-MeC₆H₄OH I gives iso-*o*-cresol-tetrachlorophthalein, m. 258–60° (decompn.); the alk. soln. is deep blue; di-Na salt, dark blue, forming a red soln. in H₂O and changing to blue on the addn. of alkali; diacetate, m. 224–7°; di-Me ether, m. 261–4° (decompn.). C. J. WEST

Transposition of trisubstituted aldehydes to disubstituted ketones. ORÉKHOFF

AND TIFFENEAU. *Compt. rend.* 182, 67–9(1926).—The transposition $\text{RRRC} \cdot \text{CHO} \cdot$

RRCH.CO.R, now identified for the 1st time, probably occurs in the majority of cases of dehydration of trisubstituted glycols of the cyclic series studied by various authors. It was first reported by Daniloff for Ph_3CCHO (cf. *J. Russ. Chem. Soc.* **49**, 282(1917); **51**, 97(1919)). Extending the study to aryldialkyl- and alkyl diarylacetaldehydes, which were of special interest because they are probably intermediate products of the dehydration of arylglycols by concd. H_2SO_4 , isomeric ketones were obtained by dissolving the aldehyde in concd. H_2SO_4 at room temp. and adding ice-water. The nature of the transposition varied with the aldehyde. Thus MePh_2CCHO gave only MePhCHCOPh , PhMe_2CCHO only PhMeCHCOMe and PhEt_2CCHO only PhEtCHCOEt , whereas EtPh_2CCHO gave both Ph_2CHCOEt and EtPhCHCOPh . In each case the transposition products were identical with those formed in the dehydration by concd. H_2SO_4 of the glycols from which the aldehydes were derived. These transpositions of aryldialkylglycols and from alkylhydrobenzoins to ketones (cf. Tiffeneau and Orékhoff, *C. A.* **15**, 3477; **16**, 1232, 2504; **17**, 3028; **18**, 70) are not of the semipinacol type, but are the result of a double migration: (1) migration of Ph, transforming the glycol to a trisubstituted aldehyde (exclusive elimination of tertiary OH) and (2) a Ph or alkyl migration, transforming the aldehyde to a ketone. The mechanism of this transportation is still in a hypothetical state. It is probably not a simple exchange, for with Ph_3CCHO heat does not favor the change but decomps. it to CO and Ph_3CH , but more likely involves a *halochromic addn. compd.* $\text{R}_3\text{CCH}(\text{OH})\text{SO}_4\text{H}$, which in turn

C. C. DAVIS

An example of an ether of a ketone hydrate. J. BOUGAULT. *Compt. rend.* **182**, 136-8(1926).—It has already been shown (cf. *C. A.* **19**, 3265) that $\text{PhCH}_2\text{CH}_2\text{C}(\text{OH})(\text{CO}_2\text{H})\text{OC}(\text{CH}_2\text{CH}_2\text{Ph})(\text{OH})\text{CONH}_2$ cannot be converted to the corresponding dibasic acid by acids or alkalis, owing to decompn. Further study shows that with HCl in HOAc, 2 different products are formed, depending upon the proportion of HCl used. They are *isomeric lactones*, m. 120° and 82° , resp., and are very different in compn. and in reactions. $\text{PhCH}_2\text{CH}_2\text{C}(\text{OH})(\text{CO}_2\text{H})\text{OC}(\text{CH}_2\text{CH}_2\text{Ph})(\text{OH})\text{CONH}_2$ (5 g.), HOAc (30 g.), HCl (d. 1.17) (20 cc.) and H_2O (80 cc.) refluxed 4 hrs. evolved CO_2 and gave a yellow sirup which, after washing with H_2O , and crystg. from Et_2O , gave the *compd.* $\text{PhCH}_2\text{CH}_2\text{CH} \begin{array}{c} \text{O} \\ \text{C}:(\text{CHCH}_2\text{Ph}) \end{array} \cdot \text{CO} \cdot \text{O}$, m. 120° (*loc. cit.*). It

formed with very dil. NaOH a *Na deriv.* (without rupture of the lactone chain) which was pptd. by excess NaOH, and which regenerated the original lactone when treated with even the weakest acids. Boiling dil. alkalis formed, by hydration, $\text{PhCH}_2\text{CH}_2\text{CHO}$ and $\text{PhCH}_2\text{CH}_2\text{COCO}_2\text{H}$, the yield of the latter being quant., that of the former very small owing to rapid resinification in the air. The 2nd product, m. 82° (*loc. cit.*) was not studied. C. C. DAVIS

Catalytic reduction of α -nitronaphthalene to α -naphthylamine. A. N. PARKETT AND ALEX. LOWY. *J. Am. Chem. Soc.* **48**, 778-82(1926).— $\alpha\text{-C}_{10}\text{H}_7\text{NO}_2$ (I) (5 g.) in 100 cc. glycol contg. 0.2 g. Pd black is reduced in 7.5 hrs. under $3\frac{1}{2}$ atm. pressure, giving 89.4% $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ (II); 84.6% in 3 hrs., and 98.4% at $6\frac{2}{3}$ atm. in 3 hrs. The % of reduction increases with an increase in temp. from 50° to 100° . The efficiency of solvents increases in the order: $\text{C}_2\text{H}_5(\text{OH})_2$, $\text{C}_2\text{H}_4(\text{OH})_2$, H_2O and iso-PrOH. Pd and Pt oxides produce high % of II in 1.5 hrs. Molten I was reduced by Pd oxide with a yield of 93.9% and with Ni with a yield of 14.3%. C. J. WEST

α -Naphthyl isocyanate as a reagent for alcohols. V. T. BICKEL AND H. E. FRENCH. *J. Am. Chem. Soc.* **48**, 747-51(1926).— $\alpha\text{-C}_{10}\text{H}_7\text{CNO}$ reacts well with primary and sec. alcs., giving good yields of urethans; tert. alcs. do not react well. The presence of moisture is not detrimental to the reaction with alcs. of low mol. wt., or with those which do not require heat for the reaction, but seriously interferes with reactions in which the mixt. is heated. The urethans are sepd. from the dinaphthylurea by its insolub. in hot ligroin. Urethans of the following alcs. were prepd.: methyl, m. 124° ; benzyl, m. 134.5° ; cinnamyl, m. 114° ; phenylethyl, m. 119° ; lauryl, m. 80° ; amyl, m. 68° ; furfuryl, m. $129-30^\circ$; m-xylol, m. 116° ; o-methoxybenzyl, m. $135-6^\circ$; ethylene glycol, m. 176° ; trimethylene glycol, m. 164° ; glycerol, m. $191-2^\circ$; ethylene bromohydrin, m. $86-7^\circ$; trimethylene bromohydrin, m. $73-4^\circ$; ethylene chlorohydrin, m. 101° ; trimethylene chlorohydrin, m. 76° ; phenylmethylcarbinol, m. 106° ; phenylethylcarbinol, m. 102° ; menthol, m. 119° ; borneol, m. 127° ; isoborneol, m. 130° ; cholesterol, m. 160° ; benzoin, m. 140° ; diphenylcarbinol, m. $135-6^\circ$; cyclohexanol, m. $128-9^\circ$; 2-methylcyclohexanol, m. $154-5^\circ$;

3-isomer, m. 122°; 4-isomer, m. 159–60°; methylhexylcarbinol, m. 63–4°; diethylcarbinol, m. 71–2°; Ph₃COH, Et₃MeCOH and citronellol did not react. Triphenylcarbinyl sym-tribromophenolate, m. 74–5°. The corresponding Bu ester could not be prepd.

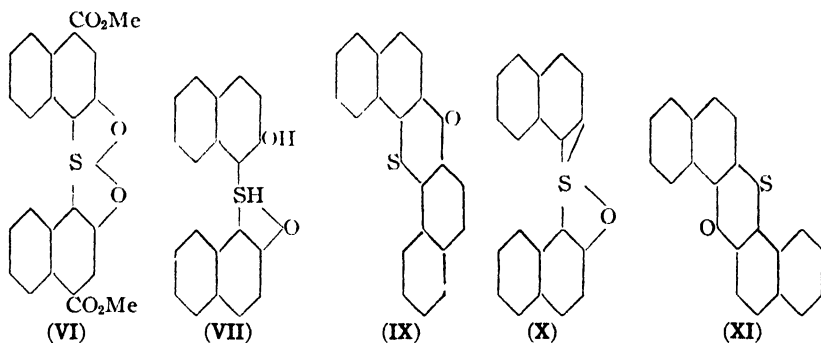

C. J. WEST

The influence of substituents on the formation and on the stability of some cyclic compounds. MICHELE GIUA. *Atti accad. Lincei* [6], 2, 343–6 (1925).—The work of Stollé and Knebel (*C. A.* 15, 3479) on the condensation of (COCl)₂ with phenols is reviewed. G.'s earlier work (*C. A.* 12, 1169) on the action of (COCl)₂ on β-C₁₀H₇OEt, which was confirmed by Staudinger (*C. A.* 15, 3445) and Stollé (*l. c.*) is reviewed. In this paper, the action of CH₂(COCl)₂ on β-naphthol (I) which was expected to give benzoxycoumarin, but gave the β-dinaphthyl malonate (II) instead, is described. 14.4 g. I in 50 cc. CS₂ and 14.1 g. CH₂(COCl)₂ were heated about 1 hr. on the H₂O bath. 12 g. AlCl₃ was then added and after HCl ceased to be evolved the CS₂ was evapd., leaving a pasty mass which was decompd with H₂O and a few drops of HCl. The pasty mass solidified slowly and was distd. with steam. The residue was crystd. from glacial AcOH and gave II, m. 146–7°. II sapond. with EtOH + KOH gave I. II does not react with FeCl₃ in H₂O or in EtOH.

R. J. WITZEMANN

2-Hydroxy-4-naphthoic acid and attempts to prepare an unsymmetrical naphthoxin. RUDOLF LESSER AND GEORGE GAD. *Ber.* 58B, 2551 9 (1925); cf. *C. A.* 20, 909; Royle and Schedler, and Butler and R., *C. A.* 17, 2178.—The present work shows beyond doubt that 2-hydroxy-4-naphthoic acid (I), m. 218–9° (cor.), has the normal structure with a double bond between C atoms 1 and 2; its acetate (II) m. 173–4° (R. and S. give 169–70°); benzoate, m. 222–3°; Me ether, prepd. with Me₂SO₄, m. 159°; chloride of II, from II in boiling C₆H₆ with SOCl₂, m. 96 7°; amide of II, m. 180–1°, converted by cautious hydrolysis with concd. KOH into the amide of I, m. 209–11°; anilide of II, m. 178–9°; anilide of I, m. 112–3°, possesses no affinity for plant fibers, unlike the 2,3-C₁₀H₆(OH)CONHPh, couples with p-O₂NC₆H₄N NPh to 1-p-nitrobenzene-azo-2-hydroxy-4-naphthoic anilide, red, m. 295–6°, sol. in concd. H₂SO₄ with cherry-red color. Me ester of I, obtained with MeOH-HCl, m. 91–2°. 1-Br deriv. of I, from I in AcOH suspension with 2 atoms Br at room temp., m. 231–2°. 1-Benzeneazo deriv. of I, red, m. 273° (decompn.), forms a monobasic Na salt, red needles with 2 H₂O. The dye obtained by coupling I with p-diazobenzenesulfonic acid (which yields a red dibasic Va salt) gives with Na₂S₂O₄ in a slight excess of NaOH and subsequent acidification with AcOH the 1-NH₂ deriv. (III) of I, m. 201° (decompn.) (yield, nearly quant.); if the Na₂S₂O₄ soln. is not acidified, the Na salt of III seps. on cooling, acidification with concd. HCl gives the HCl salt; on boiling with dil. HCl III loses CO₂ and gives 1,2-C₁₀H₆(NH₂)OH; N,O-di-Ac deriv. of III, from III in boiling Ac₂O-NaOAc, m. 225° (decompn.). With equal vols. of HNO₃ (d. 1.4) and H₂O in ice, III gives the yellow to orange 1,2-naphthoquinone-4-carboxylic acid, m. 173° (decompn.) (Heller, *C. A.* 6, 1440, gives 164–5°), whose yellow oxime, m. 181–2° (decompn.), is obtained by boiling the acid with 1 mol. NH₂OH.HCl in alc.; the isomeric 1-nitroso-2-hydroxy-4-naphthoic acid, red-brown, m. above 300° and sol. in concd. H₂SO₄ with blue-green color, is obtained in poor yield and not quite free of unchanged I when a Na₂CO₃ soln. of I contg. a large excess of NaNO₂ is poured with stirring into dil. HCl. 1,2-Diazo-oxide-4-naphthoic acid (1 g. from 3 g. III in cold H₂O rubbed to a paste with cold satd. aq. CuSO₄ and treated in ice with concd. aq. NaNO₂), yellow, deflagrates 151°, couples slowly with m-C₆H₄(OH)₂ in Na₂CO₃. 1,2,3-C₁₀H₆(NH₂)(OH)CO₂H (IV), obtained quant. by reduction with Na₂S₂O₄ of the dye obtained from p-diazobenzenesulfonic acid and 2,3-C₁₀H₆(OH)CO₂H, yellowish, m. 241° (decompn.) (Möhlau, *Ber.* 28, 3090 (1895), gives 205.5°), smoothly gives on diazotization in the usual way (drop-wise addn. of the Na₂CO₃ soln. of the IV, contg. the calcd. amt. of NaNO₂, to dil. HCl) the diazo oxide, stout dark yellow rodlets or needles with blue-black surface luster rubbing to a yellow powder, m. 182–3° (decompn.) (yield, almost quant.). The different behavior of III and IV towards HNO₃ is explained by assuming that III contains a double bond between the 1- and 2-, IV between the 2- and 3-C atoms, and that the rearrangement of the double bonds is effected only during the diazotization. The Me ester (20 g.) of I in CCl₄ with S₂Cl₂ gives 18.5 g. of the sulfide, C₂₀H₁₈O₆S (V), m. 210–1° (dibenzoate, m. 225°); 8 g. of this in cold Et₂O suspension with 20% NaOH and Br yields 6.2 g. of the dehydrosulfide, dark red, m. 188–9°, which does not react with PhNHNH₂ or other hydrazines and, therefore, has the so-called spiran structure (VI); the o-position not being occupied in this case, the non-reactivity of the VI cannot be accounted for on the basis of steric hindrance as suggested by v. Auwers and Kehrman for the corresponding deriv. of 2,3-C₁₀H₆(OH)CO₂Me. VI (4 g.) in boiling C₆H₆ with fuming HCl and Zn dust gives 2 g. of the isosulfide, m. 146°, sol. in cold dil. NaOH with yellow color and,

unlike the normal sulfide (V), oxidized back to VI in such a soln. by $K_3Fe(CN)_6$; in Et_2O in the presence of $NaHCO_3$ it quant. decolorizes I; its *dibenzoate*, m. 147–8°. All the sulfides described in the earlier papers give, even with an excess of KOH, only monobasic *K salts* while V alone forms a dibasic *salt*, and L. and G. now agree with v. A. and K. that the non-reactivity of those dehydrosulfides which did not react with $PhNHNH_2$ was due to steric hindrance as the result of the *o*-position being occupied. Although L. and his collaborators have established the structure of the isosulfides, Hinsberg (*C. A.* 18, 254) still maintains his so-called "S isomerism" theory, chiefly on the basis of the fact that Nolan and Smiles obtained from β -naphthol isosulfide (VII) a naphthoxin isomeric with that obtained from β -naphthol sulfide (VIII), and according to H., these 2 compds. cannot be structural isomers. L. and G. have confirmed the findings of N. and S. but believe that VIII loses H_2O normally and forms the sym. 2,1,2',1'-naphthoxin (IX), while VII, through the hypothetical intermediate compd. (X), gives the unsym. 1,2,2',1'-naphthoxin (XI). Attempts to prep. an unsym. naphthoxin failed. K 1-carbethoxynaphthalene-2-sulfonate, from 1,2- $C_{10}H_6(OH)SO_3H$ and $ClCO_2Et$ in alk. soln., was converted with PCl_5 into the *sulfonyl chloride*, m. 127–8°, which was reduced in MeOH suspension with Zn dust and concd. HCl to the exceedingly sensitive 1-naphthol 2-mercaptan, m. around 100°; in all attempts to condense the mercaptan with 2,1- $C_{10}H_6(OH)I$ the mercaptan decompd. before reaction set in. Neither 1,2'- nor 2,2'-dinaphthyl ether reacts with S_2Cl_2 . A mixed 4-chloro-naphthol 2'-naphthol 2,1'-sulfide, m. 167–8° (decompn.), was finally obtained (in 6 g. yield), from 17.8 g. 1,4- $C_{10}H_6(OH)Cl$ and 2- $C_{10}H_7OH$ with S_2Cl_2 refluxed in $CHCl_3$ (some 4-chloro-1-naphthol 2-sulfide, m. 172°, is also formed), but all attempts to condense the mixed sulfide to a naphthoxin failed.

C. A. R

Biacene (biacenaphthylidene) and its keto derivatives. KAROL DZIEWONSKI AND TADEUSZ LITYNSKI. *Ber.* 58B, 2539–44 (1925).—Biacenedione (biacenaphthylidenedione) (I), orange-red, m. 287–8°, is obtained in about 10% yield from acenaphthene and $K_2Cr_2O_7$ heated in AcOH 2–3 days at 40–50°; it dissolves in concd. H_2SO_4 with green color changing to red on addn. of a little concd. HNO_3 . Biacenone (biacenaphthylidenone) (II), golden yellow, m. 258°, is conveniently prepd. by refluxing acenaphthylene dibromide in concd. alc. soln. with concd. HCl for 3–4 hrs; it dissolves in concd. H_2SO_4 with intense violet color and is reprecipitated unchanged by H_2O , but if allowed to stand a long time in the soln. it undergoes a deep-seated alteration and the color changes to blue-red; its picrate, bronze-red, m. 224°. Acenaphthenone, m. 121–3°, sol. in concd. H_2SO_4 with yellow-green color, is an intermediate product in the prepn. of II and remains in the alc. mother liquors from the II. Biacene (biacenaphthylidene) (III), reddish golden yellow, m. 271–3°, can easily be prepd. by refluxing I or II with Zn dust and NaOAc in Ac_2O ; it dissolves in concd. H_2SO_4 with green color soon changing to indigo-blue in transmitted and fiery red in incident light; after a time the dichroism phenomenon disappears and the soln. finally assumes an olive-green color; its picrate, crimson, m. 214° (decompn.).

C. A. R.

Composition of rubicene. KAROL DZIEWONSKI AND JETZY SUSZKO. *Ber.* 58B, 2544–6 (1925).—As the exptl. results reported by Pummerer and Ulrich (*C. A.* 20, 412) differ materially in some respects from those obtained by D. and S., whose paper appeared in a journal not very readily accessible (*Bull. acad. Polon.* 1921, 67), D. and S. give a brief summary of their work and reproduce the results of the 4 analyses (made

on 0.15–0.19 g. samples) on the basis of which they assigned to P.'s rubicene the compn. $C_{26}H_{12}$ instead of $C_{26}H_{14}$ (found C 95.99–96.53, H 3.99–4.10%). C. A. R.

Compounds of the diphen succindene series. XII. Colorless and colored isomeric hydrocarbons of the diphen succindene series. K. BRAND AND T. SASAKI. *Ber.* **58B**, 2546–50 (1925); cf. C. A. **18**, 1660.---9,12-Dipropylidiphen succindan-9,12-diol (I), obtained in 25% yield from diphen succindan-9,12-dione (II) in C_6H_6 with $PrMgBr$ in Et_2O , m. 121–2°; boiled in $AcOH-HCO_2H$ (50:30 by vol.) or in alc. contg. a few drops of concd. HCl it gives a mixt. of the red 9,12-dipropylidiphen succindan-9,11-diene (III), m. 135–6°, and the colorless isomeric 9,12-dipropylidenediphen succindan (IV), m. 157–8°, which is oxidized by $CrO_3-H_2SO_4$ to $EtCHO$ and II. Both III and IV give with Pd -charcoal and H in aq. alc. the same 9,12-dipropylidiphen succindan (V), m. 98–9°. *Di-iso Pr isomers:* of I, prisms with 3 $MeOH$ or $EtOH$ which they quickly lose in the air, falling to a powder, m. 132–3°; of III, red to brown-red, m. 178–9°; of IV, colorless, m. 189°, oxidized by $CrO_3-H_2SO_4$ to Me_2CO and II; of V, m. 80–1°. C. A. R.

Dimorphism of furfuryl furate. J. E. ZANETTI AND P. F. KERR. *J. Am. Chem. Soc.* **48**, 794–7 (1926); cf. C. A. **19**, 1705. α -Furfuryl furate, m. 19.5°, d. 1.330, belongs to the monoclinic system, prismatic class; rhombic prism (hOl)(hkl); pinacoids (100)(001); crystal angles are given. The crystals pass with extreme ease to the β -form, the pressure exerted in removing the crystals or the mechanical disturbance caused by scratching their surface unintentionally being sufficient to cause this change. The β -form, m. 27.5°, d. 1.395, belongs to the triclinic system, pinacoidal class; pinacoids (100)(010)(hkl)(Ohl)(hkl)(hkl), crystal angles are given. The pseudomorphism of the β -form is discussed. C. J. WEST

Vinylene-homologous furals. W. KONIG. *Ber.* **58B**, 2559–66 (1925); cf. C. A. **19**, 3488; Vorländer, Fischer and Kunze, C. A. **19**, 2940.---A whole series of vinylene-homologous aldehydes, $R(CH:CH)_nCHO$ has been prepd. and studied, in the present paper are reported the results obtained with 5-[α -furyl]pentadien-1-al (I) and 7-[α -furyl]heptatrien-1-al (II) ($R = OCH_2CHCH_2CH_2C$, $n = 2$ and 3, resp.). I and II may

also be designated as α -strepto-di- and α -strepto-trivinylene-fural, resp. The max. of absorption in $\mu\mu$ and the persistency (thickness of layer in mm. down to which absorption bands persist) for the compds. $n = 0, 1, 2$ and 3 are, resp.: 272, 0.55, 314, 0.45; 350, 0.41; 373, 0.39. The colors of the addn. products formed by the 4 compds. with $SnCl_4$ in C_6H_6 are, resp.: colorless, lemon-yellow, orange, brick-red, with concd. HCl in alc.: colorless, green-yellow, orange, violet-red. Furfuracrolein ($n = 1$), m. 51°, is obtained in 60% yield from 100 g. furfural in 2 l. H_2O and 10 g. $NaOH$ at 0° treated in the course of 3.5 hrs. with 200 g. of 40% AcH and stirred 1.5 hrs. longer at 0°, protected from air and light it is indefinitely stable; in sunlight in evacuated quartz vessels it becomes discolored and deposits a substance no longer sol. in alc.; when pure, it dissolves in concd. HCl with greenish yellow color; its oxime, m. 123°. I, obtained in about 25 g. yield, under the most favorable conditions, from 100 g. furfural in 2 l. of 7.5% $NaOH$ at 20° treated in the course of 2.25 hrs. with 200 g. of 40% AcH and stirred 20 min. longer, b. 130–60°, yellow leaflets of faintly aromatic odor, m. 66°, volatile with steam, sol. in concd. HCl with orange color; oxime, very faintly yellowish white, m. 127°; phenylhydrazone, yellow, m. 153°. II, obtained in about 0.3 yield along with I, golden yellow, m. 111°, sol. in concd. HCl with violet-red color, gives a deep green color with salts of aromatic amines; phenylhydrazone, golden yellow, m. 183°, decomp. in the light. C. A. R.

Substituted pyrrole alcohols, pyrrolethioaldehyde and a pyrrolamine. HANS FISCHER AND ADOLF STERN. *Ann.* **446**, 229–41 (1925). Pyrrole alcs. are obtained by catalytic reduction in $EtOH$ or by reduction with $Al-Hg$ in Et_2O of pyrrole-aldehydes. 2,5-Dimethyl-3-carbethoxy-4-hydroxymethylpyrrole, m. 131°; heating at 150° for 2 hrs. gives the corresponding methane deriv. 2,4-Dimethyl-3-carbethoxy-5-hydroxymethylpyrrole, m. 119°. 2,4-Dimethyl-5-carbethoxy-3-hydroxypyrrole, m. 146°. Catalytic reduction in $AcOH$ gives the corresponding methane deriv. directly. The action of H_2S upon the pyrrole-aldehyde in $EtOH-HCl$ gives the thio deriv.; 2,5-dimethyl-3-carbethoxy-4-thioformylpyrrole, m. 231°; 2,5-dimethyl-5-carbethoxy-3-thioformylpyrrole, m. 246.5°; 1-phenyl-2,5-dimethyl-3-carbethoxy-4-thioformylpyrrole, m. 246°. 1,2,5-Trimethyl-3-carbethoxypyrrole-4-azobenzenesulfonic acid, orange-yellow leaflets. $Al-Hg$ and the NO_2 deriv. give 2,4-dimethyl-5-carbethoxy-3-aminopyrrole, m. 125.5°, whose picrate, m. 191° and HCl salt, m. 291°. Diazotized, it gives with $\beta-C_{10}H_7OH$ the 3-azo- β -naphthol, light red, m. 234°. Me_2SO_4 gives the compd. $C_{11}H_{13}O_2N_2$, m. 87°. C. J. WEST

Synthesis of 2,4-dimethyl-5-ethylpyrrole-3-propionic acid. HANS FISCHER AND BRUNO WALACH. *Ann.* **447**, 38-48 (1926).—Improved methods are given for prep. 2,4-dimethylpyrrole (32%) and 2,4-dimethyl-5-ethylpyrrole (77%); the latter in HCN, satd. with HCl, gives the imine-HCl, which is decompd. with ice and finally made alk. with 30% NaOH, giving 77% of 2,4-dimethyl-5-ethyl-3-formylpyrrole (I), m. 128°. *oxime*, m. 118.5°; *nitrile*, m. 112°; *aldazine*, m. 207°; *semicarbazone*, yellow, m. 203°; *azlactone*, orange-red, m. 193°; *benzoylaminoacrylic acid* from this, m. 183°. $N_2H_4 \cdot H_2O$ and Et_2O give the isomeric phyllopyrrole (2,3,4-trimethyl-5-ethylpyrrole), b_p 114-5°, m. 38-9°. I, $CH_2(CO_2H)_2$ and piperidine in $EtOH$ give 58% of 2,4-dimethyl-5-ethylpyrrole-3-acrylic acid, m. 205°, which is reduced by Na-Hg in dil. NaOH to the 3-propionic acid, m. 43-4°. 2,4-Dimethyl-3,5-diethylpyrrole, $C_8H_{14}(CO)_2O$ and $AcOH$, heated at 190° for 6 hrs. gives kryptopyrrole, identified as the picrate, m. 135°. 2,3,4-Trimethylpyrrole is obtained in 70% yield from 2,4-dimethyl-5-carbethoxy-3-formylpyrrole, $N_2H_4 \cdot H_2O$ and $EtONa$ by heating 12 hrs. at 140-60°.

Synthesis of tetra(2-ethyl-3-propionyl-4-methylpyrrol)ethylene, xanthopyrrole-carboxylic acid and transposition of several pyrroles. HANS FISCHER AND JOSEF KLARER. *Ann.* **447**, 48-63 (1926).—2-Ethyl-3-propionyl-4-methyl-5-carboxypyrrole, m. 180° (dec. compn.), results by heating the carbethoxy deriv. with concd. $EtOH-KOH$ 8 hrs. on the H_2O bath; heated above its m. p., it gives 2-ethyl-3-propionyl-4-methylpyrrole, b. 283°, m. 90°. With $HCHO$ and HCl there is formed bis-[2-ethyl-3-propionyl-4-methylpyrrole]methane, needles, which, heated in $EtOH$ with $FeCl_3$, yields the methene-III (I), bright red, m. 183°; this also results from the free pyrrole, HCO_2H and HCl, the free methene, yellow, m. 167°; *Cu salt*, yellow with metallic luster, m. 220°; *Co salt*, dark green, m. 274°; *Zn salt*, orange-yellow needles; *Cd salt*. 2-Ethyl-3-propionyl-4-methylpyrrolazobenzene-sulfonic acid, prisms which explode on heating. 2-Ethyl-3-propionyl-4-methylpyrrole-phthalide, yellow, m. 105° (88% yield). 2-Ethyl-3-propionyl-4-methyl-5-formylpyrrole, m. 140°, from the pyrrole HCN and HCl; *oxime*, m. 212°. Tetra-[2-ethyl-3-propionyl-4-methylpyrrol]ethane, m. 249°, from the pyrrole, glyoxal HCl or HNO_3 ; if the condensation is carried out with $AcOH$ and 1-2 drops concd. H_2SO_4 the product is deep red and shows 2 bands at 526-504 and 487.7-468.4 μ . $FeCl_3$ gives the corresponding ethylene deriv., yellow, m. 209°; with concd. $FeCl_3$ soln. there results a quant. yield of I. Reduction with Na-Hg at 35° gives the ethane, but $HI-AcOH$ gives 2-ethyl-4-methylpyrrole (II), b_{40} 93°, also obtained by heating 2-ethyl-3-propionyl-4-methyl-5-carbethoxypyrrole (III) with H_2SO_4 ; *picrate*, yellow, m. 86°; *azobenzene-sulfonic acid deriv.* III and $N_2H_4 \cdot H_2O$ in $EtOH$ give 2-ethyl-3-propyl-4-methylpyrrole, golden yellow oil, b_{12} 82°, unstable in the air, forming a resin; *picrate*, m. 168°. The methene of II was analyzed as the perchlorate, bright red, decomp. 240°, the *Cu salt* green leaflets with metallic luster, the *Co salt*, green leaflets with a metallic luster, and the *Fe salt*, m. 190°. *Et* 2-ethyl-4-methyl-5-carbethoxypyrrole-3- β -methylmalonate, m. 78°, by heating III, $MeCH(CO_2Et)_2$ and concd. HCl 3 hrs.; sapon. gives the free acid, m. 162°, with evolution of CO_2 and formation of 2-ethyl-4-methyl-5-carbethoxypyrrole-3-propionic acid, m. 138°; sapon. gives 90% of 2-ethyl-4-methyl-5-propionic acid (xanthopyrrolecarboxylic acid), m. 126° (*picrate*, m. 143°; *phthalide*, yellow, m. 133°).

C. J. WEST

Thiazoles. IX. Further studies on derivatives of 2-phenylbenzothiazole M. T. BOGERT AND HUGH BLAKE CORBITT. *J. Am. Chem. Soc.* **48**, 783-8 (1926); cf. C. I. **20**, 600.—6-Chloro-2-phenylbenzothiazole, m. 156.7° (all m. p. are cor.), results in 30-5% yields by the action of PCl_5 upon 2-phenylbenzothiazole, in 21.4% yield from the 6- NH_2 deriv. through the diazo reaction and in very low yields from *p*- ClC_6H_4NH :CPh and S at 252°. It does not give a higher Cl deriv. nor was the Cl replaced by Br with LiBr. The 6- NO_2 deriv., m. 196°. If 20% excess HNO_3 is used a *di-NO_2* deriv. is formed, m. 223°. 2-[*m*-Nitrophenyl]benzothiazole, m. 186.8-7.3°, in 35% yield from (*o*- $H_2NC_6H_4S$) $_2Zn$ and *o*- $O_2NC_6H_4COCl$. Reduction with Sn and concd. HCl gives 32% of the *NH_2* deriv., m. 140.4-40.9°; the $EtOH$ soln. shows a greenish blue fluorescence. 6-Hydroxy-2-phenylbenzothiazole, m. 228-9° (39.3% yield from the NH_2 deriv. through the diazo compd.). 2-[*p*-Hydroxyphenyl]benzothiazole, m. 228.6-29°, results in 69% yield from the corresponding NH_2 deriv. or in 47% yield from *p*- HOC_6H_4CHO . Nitration gives a bright yellow mononitro deriv., m. 199.2-97° (47.1% yield), sol. in NaOH with a yellowish red color, which is reduced to an *NH_2* deriv., m. 234.5-5.5° (20% yield), whose solns. exhibit a weak bluish fluorescence and darken on exposure to the air. The insol. reddish orange diazonium salt couples with β - C_6H_4OH to give a rich violet or purple ppt.

C. J. WEST

Benzo- γ -pyrones. G. WITTIG, FR. BANGERT AND H. E. RICHTER. *Ann.* **446**, 155-204 (1925).—2- HOC_6H_4Ac and $AcOEt$ with Na give 65% of 2-acetylacetophenol.

m. 90.5–1.5°; soln. in concd. H_2SO_4 gives a *quant.* yield of 2-methylchromone; boiling with Ac_2O and $AcONa$ for 2 min. gives 85% of 2-methyl-3-acetochromone, m. 88.5–9.5°. 2-Acetylaceto-5-methylphenol, m. 76–7° (60% yield); 2,7-dimethylchromone, b_{15} 192–3°, m. 97.5–8.5°; the 3-aceto deriv., m. 107.5–8.5° (85–90% yield). 2,6-Dimethyl-3-acetochromone (I), m. 114.5–5.5° (85–90% yield). 2-Acetylaceto-3,5-dimethylphenol, m. 116–7° (75–80% yield), gives quant. 2,5,7-trimethylchromone, b_{15} 177°, m. 55 6°, also gives 90% of the 3-aceto deriv., m. 112–3°. 2-Acetylaceto-1-naphthol, deep yellow, m. 110.5–1.5° (85–90% yield), gives quant. 2-methyl-[1,2-naphtho- γ -pyrone], m. 174–4.5°, and a nearly theoretical yield of the 3-aceto deriv., m. 143–4°. 1-Acetylaceto-2-naphthol, m. 152° (decompn.), gives quant. the pyrone derivs. Heating a mixt. of 20 g. 2,4-AcMeC₆H₃OH, $AcOH$ and $AcONa$ 18–20 hrs. during which time the temp. rises from 160° to 220° gives a mixt. of I, 2,6-dimethylchromone (II) and 4,6-dimethylcoumarin (III); the reaction mixt. in $AcOH$, treated with $NH_2OH \cdot HCl$ and $AcONa$, gives a mixt. of the monoxime of I, yellow, m. 100–100.5°, and the dioxime, m. 222–4°, sepd. by the greater insoly. of the monoxime in C_6H_6 ; both of them are sepd. by their soly. in $NaOH$; II and III are sepd. by transforming II into its oxonium salt by HCl ; the above mixt. may also be sepd. by pptg. II as its oxonium salt from Pt_2O , then removing I as the oxime mixt. The relative ams. formed are: using the 1st method of sepn., 52% I, 16% II and 24% III; using the 2nd method, 48% I, 12% II, 24% III. In the case of 2-HOC₆H₄Ac the acid method cannot be used, since 2-methylchromone does not form a HCl salt; the reaction mixt. is treated with $EtONa$ and the product liberated by $AcOH$ is taken up in Pt_2O and extd. with $NaOH$, the Pt_2O contains the 4-methylcoumarin (1.8 g. from 30 g. HOC₆H₄Ac); the alk. ext. contains the 2-HOC₆H₄COCH₂Ac, which is transformed into 2-methylchromone (14% of the theory from HOC₆H₄Ac) by H_2SO_4 . 2,6-AcMeC₆H₃OH, Ac_2O and $AcONa$ give 35% 2,8-dimethylchromone and 15% 4,8-dimethylcoumarin. 2,5-AcMeC₆H₃OH gives 20% 2,7-dimethylchromone and 12% of 4,7-dimethylcoumarin. 2,3,5-AcMeC₆H₃OH gives 57% of 2,5,7-trimethyl-3-acetochromone and 6.5% 2,5,7-trimethylchromone, whose oxonium chloride, m. 152° (decompn.). 2-Aceto-6-nitrophenol, yellow needles, m. 98.5–9.5°, in 10% yield from 2-HOC₆H₄Ac and HNO_3 in $AcOH$; the poor yield is due to the oxidation to the acid. 2-Aceto-4-methyl-6-nitrophenol (IV), yellow, m. 130–30.5°, in 77% yield from the phenol, H_2SO_4 and KNO_3 ; more energetic nitration gives 25% of a 2,6-dinitro deriv., m. 147–7.5°, also obtained in 80% yield from the mononitro deriv. IV, Ac_2O and $AcONa$ give 25% of 2,6-dimethyl-3-aceto-8-nitrochromone, brown, m. 146.5–7.5°. 2,1,4-AcC₆H₃(OH)₂ and $AcCl$ give the di-Ac deriv., which, heated with Ac_2O and $AcONa$ 15 hrs. at 180°, gives 2-methyl-3-aceto-6-acetoxychromone, m. 120–1°, sapond. by 4 parts concd. HCl and 1 part H_2O to 2-methyl-3-aceto-6-hydroxychromone, m. 215 6°. Heating 2-methyl-7-acetoxychromone with $AlCl_3$ gives 66% of 2-methyl-7-hydroxy-8-acetochromone (V), m. 186–7°; $EtONa$ gives 2,4-diaceto-1,3-dihydroxybenzene, m. 88 9°. Heating V with Ac_2O and $AcONa$ 2.5 hrs. gives α, α' -dimethyl- β' -aceto-benzo-1,2,5,6-di-[γ -pyrone], m. 210 1°. 4-Chlorophenyl propionate, b. 234–6°; with $AlCl_3$ it gives 2-propionyl-4-chlorophenol, m. 56.5–7.5°, whose propionate, b_{11} 170°. Ac_2O and $AcONa$ give 95% of 2,3-dimethyl-6-chlorochromone. $(EtCO)_2O$ and $EtCO_2Na$ give 95% of 2-ethyl-3-methyl-6-chlorochromone, m. 66–7°. $(ClCH_2CO)_2O$ and $ClCH_2CO_2Na$ give 50% of 2-chloromethyl-3-methyl-6-chlorochromone, m. 125.5–6.5°. 4,2-Me($EtCO$)C₆H₃OH, Bz_2O and $BzONa$ give 86% of 3,6-dimethylflavone, m. 93°. 4-Chlorophenyl butyrate, b. 249–51°; 2-butyro-4-chlorophenol, m. 49–50°; 2-methyl-3-ethyl-6-chlorochromone, m. 103–4° (95% yield); 3-ethyl-6-methylflavone, m. 73–4° (70% yield). 3-Propyl-6-methylflavone, b_{12} 265°, m. 77–8° (85% yield). 3-Isopropyl deriv., m. 150° (85% yield). 2-Phenylaceto-4-chlorophenol, b_{20} 280–5°, m. 66–7°; 2-methyl-3-phenyl-6-chlorochromone, m. 127–8°. 2,6-Dimethyl-3-phenylchromone, b_{10} 229–30°, m. 91° (80% yield). 2,3-Diphenyl-6-chlorochromone, m. 178–9° (95% yield); monoxime, pale yellow, m. 206–6.5°. 2,3-Diphenyl-6-methylchromone, m. 170° (95% yield). 2-Styryl-3-phenyl-6-methylchromone, m. 179°. 2-Methyl-3,6-dichlorochromone, yellowish, m. 155.5–6.5°. 2,6-Dimethyl-3-chlorochromone, m. 145–6°; the by-product, 2,6-dimethyl-3-hydroxychromone (VI), m. 188–9°, was synthesized from 4-methylphenyl bromoacetate, b_{60} 180–1°, through 2-bromoaceto-4-methylphenol, m. 45.5–6.5°, and the Ac deriv. of VI, m. 119.5–30.5°. 4-Chlorocoumaranone, Ac_2O and $AcONa$ give 3-acetoxy-4-chlorocoumarone, b_{20} 165–7°, m. 30.5–1°; heating with 30% H_2SO_4 gives 2-keto-1,2'-dehydro-1,2'-di-[4-chlorocoumarin], red, m. 210–1°; heating at 190° gives a yellow modification, which m. 321°. 4-Chlorocoumaranone semicarbazone, m. 237–8° (decompn.). 2-Aceto-4-chlorophenyl acetate, b_{11} 156–7°; during the distn. there is formed some 2-methyl-3-aceto-6-chlorochromone, m. 126.5–7°. Heating 2,4-ClAcC₆H₃OH (or its Ac deriv.) with $(EtCO)_2O$ and $EtCO_2Na$ for 5 hrs. at 190° gives a mixt. of about 4 parts 3,4-di-

methyl-6-chlorocoumarin, m. 140–1°, and 1 part *2-ethyl-6-chlorochromone*, m. 137–8°, sepd. by the EtONa method. $(\text{PrCO})_2\text{O}$ and PrCO_2Na give *2-propyl-3-butyro-6-chlorochromone*, m. 65–6°, and a small amt. of a compd. m. 120–5°, possibly *3-ethyl-4-methyl-6-chlorocoumarin*. Bz_2O and BzONa give a mixt. of *6-chloroflavone*, m. 181°, isolated through the action of EtONa, giving *2-benzoylaceto-4-chlorophenol* (VII), yellow, m. 107–8°, and *3-benzoyl-6-chloroflavone* (VIII). BzCl gives the benzoate of VII, m. 128.5–9.5°; attempts to condense this to VIII failed. *2-Formylaceto-4-chlorophenol*, m. 148–9°, in 1.3 g. yield from 3 g. *2,4-AcClC₆H₃OH*, HCO_2Et and Na; soln. in concd. H_2SO_4 gives quant. *6-chlorochromone*. *2,4-AcClC₆H₃OH* (5 g.), 10 g. PhCH_2COCl and 12 g. AcOPh give 6 g. *3-phenyl-4-methyl-6-chlorocoumarin*, m. 190.5–1.5°. *2-Benzoyl-4-chlorophenol*, m. 93–4°; Ac_2O and AcONa give *4-phenyl-6-chlorocoumarin*, m. 147–8°. PhCH_2COCl and $\text{PhCH}_2\text{CO}_2\text{Na}$ give *3,4-diphenyl-6-chlorocoumarin*, pale yellow, m. 163.5–4°. *2-Acetylaceto-3,5-dimethylphenyl Me ether*, m. 59–60°. *2-Aceto-4-chloro-5-methylphenyl Me ether*, m. 79–80°. *2-Aceto-4-chloro-5-methylphenyl acetate*, b_{12} 165–7°, m. 35–6°; with $(\text{EtCO})_2\text{O}$ and EtCO_2Na there results 65% of *3,4,7-trimethyl-6-chlorocoumarin*, m. 162–3°. *2-Methyl-4-acetophenyl acetate*, m. 60–1°; propionate, b_{14} 168–9° (semicarbazone, m. 192–3°). *2,6-Dimethyl-3-propionylchromone*, m. 81–2°. *2-Isobutyro-4-chlorophenol*, Ac_2O and AcONa give *2-acetoxy-2,3,3-trimethyl-6-chloro-8-acetochromanone*, b_{12} 176–9°, m. 79.5–80°; heating with 2 *N* NaOH 0.25 hr. gives iso-PrAc and *3-aceto-5-chlorosalicylic acid*, m. 173–4°. The theory of the reactions is discussed.

C. J. WEST

Some derivatives of 4-aminopyridine. ERNST KOENIGS, HANS FRIEDRICH AND HANS JURANY. *Ber.* 58B, 2571–6 (1925); cf. Chichibabin and Ossetrova, *C. A.* 20, 396.—The methiodide of 4-aminopyridine (I), prepd. according to C. and O., m. 184–5° (C. and O., 187–8°); it is apparently more stable towards alkalis than the isomer of the α -series, for it is repptd. mostly unchanged from H_2O by concd. KOH. Treated with AgCl and then with H_2PtCl_6 it gives an orange chloroplatinate, m. 230–2° (decompn.) which, with C. and O., the authors believe is identical with that obtained from *N*-methyl-4-pyridone-imide (for which C. and O. give 226–7°). They do not think, however, that the methiodide is a pyridone-imide but rather that the *N*-methylpyridone-imides are changed back by acids into the corresponding salts of *N*-methylpyridines which would explain what C. considers the "very remarkable" behavior of the former towards alkalis and acids, viz., that alkalis smoothly decomp. them into NH_3 and *N*-methylpyridones while, unlike the ketone-imides, they are resistant towards acids. *4-Methylaminodipicolinic acid* (II), from the 4-Cl acid and 33% NH_2Me at 150°, reddish, m. 245–55° (foaming); occasionally other products were obtained, probably because the temp. rose too high; in 1 case was obtained the *dimethylamide* of II, m. 269°, easily sol. in acids and repptd. by alkalis. Carefully distd. *in vacuo* II gives about 50% 4-methylaminopyridine, faintly yellow, m. 108–10° (C. and O., 115–8°); picrate, yellow, m. 172° (C. and O., 168.5–9.0°); chloroplatinate, orange, m. 232° (C. and O., 214–5°). *4-Dimethylaminopicolinic acid* (7.8 g. from 7 g. of the 4-Cl acid with 33% NH_2Me at 140–50°), yellowish brown, m. 248° (decompn.), sol. in alkalis and hot dil. HCl, gives on distn. under atm. pressure 70% of *4-dimethylaminopyridine* (III), m. 114°, which, from its structure, cannot rearrange into a pyridone-imide, yet still closely resembles I. It forms, to be sure, on evapn. of its soln. in excess of HCl, a *HCl* salt, m. 76°, which, however, is apparently partially hydrolyzed (Cl, only 18.3%); chloroplatinate, orange, m. 265° (decompn.); chloroaurate, red-yellow, m. 176–8°; picrate, yellow, m. 204°. In these salts III functions as a mono-acid base. *4,4'-Dipyridylamine-2,6-dicarboxylic acid* (5 g. from 4.5 g. 4-chlorodipicolinic acid and I at 150°), m. 255° (decompn.), sol. in alkalis and concd. acids; *2,6,2',6'-tetracarboxylic acid* (9 g. from 6 g. 4-chlorodipicolinic acid and 4-aminodipicolinic acid at 150°), brownish, m. 272° (decompn.), sol. in alkalis and concd. acids. The tetra- CO_2H acid on cautious dry distn. gives in moderate yields *4,4'-dipyridylamine*, light yellow, sinters about 110°, m. 138°, does not evolve NH_3 with boiling NaOH, gives no color in H_2SO_4 with HNO_3 . *chloroplatinate*, of the base red-yellow needles with 1 H_2O , decomp. above 280°. *picrate*, lemon-yellow, m. 170–4°; the corresponding derivs. from the di- CO_2H acid m. 134°, 260° and 168–70°, resp., and are believed to be identical with those obtained from the tetra- CO_2H acid.

C. A. R.

Preparation and properties of methylisopropylquinoline yellow. MAX PHILLIPS AND M. J. GOSS. *J. Am. Chem. Soc.* 48, 823–6 (1926).—Cymidine (64 g.), 80 g. concd. HCl, 60 g. paraldehyde and 30 g. nitrocymene give 22.5% of *methylisopropylquinoline* (2,8-dimethyl-5-isopropylquinoline), m. 78.2° (cor.), mol. wt. in boiling C_6H_6 , normal; chloroaurate, yellow micronedles. With $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$ and ZnCl_2 it gives 61% of *methylisopropylquinoline yellow* (*methylisopropylquinophthalone*), yellow, m. 220.4°.

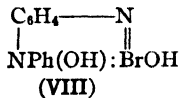

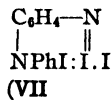

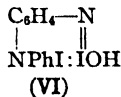

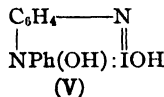

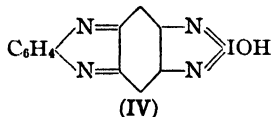

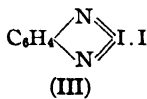

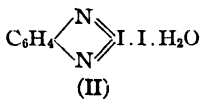

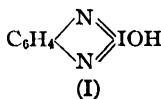

Heated with fuming H_2SO_4 (23% SO_3) at 150° for 2 hrs. and then neutralized, there resulted the *Na disulfonate deriv.*, yellow, dyes wool and silk a greenish yellow; its fastness is equal to that of the corresponding deriv. of quinoline yellow. A comparison of the absorption of these 2 new dyes and of the corresponding quinoline yellow and its disulfo deriv. failed to indicate any appreciable displacement in the absorption max. through the Me-iso-Pr substitution.

C. J. WEST

Condensation of 9-methylacridine with formaldehyde and the preparation of 9-acridinecarboxylic acid. A. W. HOMBERGER AND H. JENSEN. *J. Am. Chem. Soc.* **48**, 800–2 (1926).—9-Methylacridine and 20% HCHO give 75% of *acridyl monomethylol* (I), yellow, m. $155-6^\circ$; *HCl salt*, yellow needles; *picrate*, golden brown, m. 186° ; *Bz deriv.*, m. 159° . With 40% HCHO there results *acridyldimethylol*, S-yellow, m. 194° ; *HCl salt*, dark yellow, m. $250-65^\circ$ (decompn.); *picrate*, yellow, m. 195° . Oxidation of I with CrO_3 in H_2SO_4 gives acridine-9-carboxylic acid, yellow, m. 300° (decompn.).

C. J. WEST

Heterocyclic compounds containing quinevalent iodine or bromine. G. HUGEL. (*Compt. rend.* **182**, 65–7 (1926)).— $\text{C}_6\text{H}_4(\text{NH}_2)_2$ is so easily oxidized that even FeCl_3 forms 2,3-diaminophenazine. By using HIO_3 or HBrO_3 , intermediate products of a type hitherto unknown were isolated. Very dil. cold aq. solns. of $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$ and HIO_3 (equimol. wts.) form instantly an amorphous black ppt. (exothermic reaction), which is but slightly sol. in all solvents, giving a yellow-brown color. From its analogy with piazthiol, the name *piaziodonium hydroxide* is suggested, the constitution being I. It is a very feeble base and does not form salts with concd. or dil. acids, except HI. In aq. suspension with HI (*i. e.*, $\text{H}_2\text{SO}_4 + \text{KI}$) it is converted to another black, amorphous compd. of the compn. II, which crysts. at 30° to the compd. III. At $50-5^\circ$ this suspension again changes, becoming greenish and still less sol. Heated to boiling, I is liberated, and on cooling derivs. of 2,3-diaminophenazine and 2,3-hydroxyaminophenazine are obtained. This new reaction is not limited to $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$. Thus 2,3-diaminophenazine gives the compd. IV and $\text{o-H}_2\text{NC}_6\text{H}_4\text{NHPh}$ gives the compd. V and compd. VI, metallic green crystals. The iodonium function of VI reacts only with difficulty, but if 1:1 H_2SO_4 and a large amt. of KI are used, the compd. VIII is obtained, metallic blue-black crystals. HBrO_3 forms analogous compds. but not HClO_3 . $\text{o-H}_2\text{NC}_6\text{H}_4\text{NHPh}$ and HBrO_3 give the compd. VIII, metallic green crystals.

C. C. DAVIS

Some orthoxazine derivatives. E. P. KOHLER. *J. Am. Chem. Soc.* **48**, 754–63 (1926).—Triphenylbutanetrione oxime (I) (15 g.), in 100 cc. abs. MeOH, boiled 20 min. gives an av. yield of 65% of 3,4,6-triphenyl-5-hydroxy-6-methoxyorthoxazine (II), turns red at 160° , m. 173° (decompn.); all solus. are yellow, that in CHCl_3 turning more or less rapidly pink and purple. II, suspended in a small amt. of Et_2O , gradually deposits I, while in MeOH there appears the hydroxyisoxazoline; II is stable in the dry state in the dark but in the light gradually turns yellow. *Na deriv.*, colorless but yellow in soln. *Benzoate*, m. 163° and cannot be hydrolyzed to II; O_3 gave only small amts. of benzil and $\text{PhCH(OH)CO}_2\text{H}$. *Me deriv.*, m. 147° (decompn.), from MeI and MeONa. II and PhMgBr give 3,4,6,6-tetraphenyl-5-hydroxyorthoxazine (III), lemon-yellow, m. 220° (decompn.). *Benzoate*, m. 217° . 4-Br deriv., crystg. with 1 C_6H_6 , m. 160° . 4-Cl deriv., m. 165° . Neither deriv. is attacked by O_3 . 4-Nitro deriv., m. 150° (decompn.). III, EtI and EtONa give 2-ethyl-3,4,6,6,5-ketoorthoxazine, m. $167-8^\circ$; the corresponding *Me deriv.*, m. $189-90^\circ$.

C. J. WEST

Chemical studies on polychrome methylene blue. W. J. MACNEAL AND J. A.

KILLIAN. *J. Am. Chem. Soc.* **48**, 740-7(1926).—Methylene blue (I) treated with $K_2Cr_2O_7$, both in rather high dilns., gives the steel-blue *dimethylene blue chromate*, $(C_{16}H_{18}N_3S)_2CrO_4 \cdot 6H_2O$; EtOH removes I. Heating this with dil. HCl without access of air gives methylene azure B (trimethylthionine) (II) (Kehrmann, *Ber.* **39**, 140; (1906)), which may be salted out as the bromide, chloride, $ZnCl_2$ double salt or the iodide; the chloride is the most, the iodide the least sol. in H_2O . The dye is unstable and in hot H_2O tends to oxidize to form III. Oxidation of methylene blue with free access of air gives methylene azure A (III) if the reaction be acid, as does the oxidation of the $ZnCl_2$ salt of II; it is less sol. than II and may be salted out readily in the form of the chloride. Dimethylthionine or methylene violet of Bernthsen may be prep'd from II or III by heating in dil. alk. soln. in the presence of a complex sol. NH_4 salt of Ag or Cu or in the presence of alk. zincate or chromate. The metal evidently enters into the formation of a very sol. dye ion and tends to protect the respective free base from pptn. until hydrolysis has sep'd. the metal amine group from the dimethylthionine residue with the pptn. of the latter. Better yields are obtained from methylene blue than from the azures. These reactions lend support to the *p*-quinonoid conception of Bernthsen and of Hantzsch in regard to the structural formula of the methylene blue dyes. C. J. WEST

What is an alkaloid? E. J. SCHORN. *Pharm. J.* **116**, 113-6; *Chemist & Druggist* **104**, 161-3(1926).—An exact chem. definition of an alkaloid is difficult if not impossible to formulate as shown by a crit. analysis of 13 standard definitions. Pptn. with alkaloidal reagents, including the Sb reagent of Caille and Viel (*C. A.* **17**, 2289) may supply a practical basis for the characterization of alkaloids. In discussion, Barger said that colchicine does not fit into any of the suggested definitions because of its unusual chem. structure. S. WALDBOTT

Dyes from the alkaloids of ipecacuanha. F. L. PYMAN. *J. Am. Chem. Soc.* **48**, 836(1926).—Reply to Palkin and Wales (*C. A.* **19**, 2550). Neither emetine, *O*-methyl psychotrine nor emetamine couples with *p*- $O_2NC_6H_4N_2X$ but psychotrine gives a dye, whose NaOH soln. is purple. C. J. WEST

Dyes from the alkaloids of ipecacuanha. A reply. S. PALKIN AND H. WALES. *J. Am. Chem. Soc.* **48**, 836-7(1926).—A reply to Pyman (preceding abstr.). Ipecac must contain a hitherto undetected alkaloid which either is an amine or, if a phenol, is not removed from its soln. in Et_2O by alkali. C. J. WEST

So-called ecgonidine dibromide of Einhorn. HANS LINDEMANN AND HERMANN HEINEMANN. *Ann.* **447**, 85-96(1926); cf. Einhorn, *Ber.* **23**, 2874.—Ecgonidine-HBr and Br in AcOH give the *perbromide*, $C_8H_{14}O_2NBr_4$, m. 154° (decompn.); this is unchanged by warm AcOH but H_2O , EtOH or Me_2CO gives the HBr salt, m. 222° . The HCl salt likewise gives a perbromide, m. 242° , which, warmed with AcOH, yields 3-bromo-4-chlorotropam-2-carboxylic acid-HBr, m. $186-9^\circ$ (82.5% yield); with Ag_2CO_3 the free acid, m. 168° , results. With dil. HCl or upon crystg. the HBr salt from HCl, there results the *N*-HCl salt, m. 214° , whose *chloroplatinate*, yellowish red, decomp. at 250° , and *chloroaurate*, yellow, m. 214° . The above HBr salt, reduced by $SnCl_2$ and concd. HCl, gives a mixt. of ecgonidine-HCl and HBr. The possible constitution of these compds. is discussed. C. J. WEST

Digitoxin. A. WINDAUS AND C. FREESE. *Ber.* **58B**, 2503-10(1925).—Digitoxin (I) was purified by digesting the crude glucoside with about 20 parts $CHCl_3$, evap. the ext., crystg. the residue from dil. alc. (after treatment with blood charcoal), pptn. from $CHCl_3$ with Et_2O and recrystg. from boiling $AcOEt$, dil. alc. or $CHCl_3$ - Et_2O until pearly rectangular tables, m. $255-7^\circ$ and easily sol. in $CHCl_3$, were obtained. The losses were very large; "digitaline crystallise" yielded about 34% purified I and much material difficultly sol. in $CHCl_3$, Merck's "Digitoxin crystall." gave 55% I and no $CHCl_3$ insol. material, while the crude glucosides of digitalis leaves obtained from various firms yielded 10-35% I and up to 25% gitoxin. Pure I crystd. from $CHCl_3$ - Et_2O or $AcOEt$, m. $255-6^\circ$, from aq. Me_2CO 255° , from aq. EtOH $233-5^\circ$ (air-dry); 1 g. dissolves in 10.8 g. $CHCl_3$ at 10° and in 380 g. $AcOEt$ at 20° ; air-dried, it contains C 63.04, H 8.37%, while the vacuum-dried product has C 63.99-64.25, H 8.50-8.74, mol. wt. in camphor 682-827 (av. 746), mol. wt. by titration 694-732 (av. 708). These values agree well with those calcd. for the formula $C_{41}H_{66}O_{13} \cdot H_2O$ for the air-dried and $C_{42}H_{66}O_{13} \cdot 0.5H_2O$ for the vacuum-dried product. As noted by Cloetta (*C. A.* **15**, 707) distn. of I in a high vacuum yields a sublimate (II), the compn. of which, however (C, C 55.65, H 7.98; W. and F., 55.67, 8.03%) agrees better with the formula $C_8H_{10}O_2$ than with that ($C_8H_{14}O_4$) given by C. II, therefore seems to be an anhydro digitoxose. Further evidence in favor of this view is the fact that, while according to C.'s formulation hydrolysis of I should give 47.21% digitoxigenin, W. and F. in an expt

carried out with all the precautions usual in quant. analysis actually obtained 49.15%; the formulation which they suggest (without claiming that its correctness has been proved), viz., $C_{42}H_{86}O_{13} \cdot 0.5H_2O + 3H_2O \rightarrow C_{24}H_{38}O_4 + 3C_6H_{12}O_4$ calls for 49.3%. According to W. and F.'s formula is, therefore, closely related to gitoxin, $C_{40}H_{78}O_{14}$, from which it differs only by one O atom; both glucosides split off 3 mols. digitoxose and contain aglucones likewise differing only by one O atom. To test whether both really have the same C skeleton, the method of Bandte (*C. A.* 17, 3746) and of Schwarte (*C. A.* 20, 208) was followed. Anhydrodigitoxigenin, m. 183–4°, with colloidal Pd and H in aq. MeOH gave 75% of the *tetrahydro deriv.* (III), m. 146–7°, which with CrO_3 yielded *tetrahydroanhydrodigitoxigenone* (IV), m. 240–1° (oxime, m. 217°; (decompn.)), and this by Clemmensen's method gave the *HO lactone*, $C_{24}H_{38}O_2$ (V), m. 181°. III, IV and V are, however, not identical but isomeric with the corresponding compds. obtained from dianhydrodigitoxigenin (digitaligenin). It would seem, therefore, that the 3 cardiac diacides of digitalis thus far prepd. in pure state are derived from 2 singly unsatd. HO lactones, $C_{24}H_{36}O_4$ and $C_{24}H_{36}O_5$, both of which contain 4 hydrogenated rings and are, therefore, closely related to the bile acids. On dehydration, hydrogenation and a few other chem. transformations they are converted into 2 satd. lactones, $C_{24}H_{38}O_2$, which are isomeric (presumably stereoisomeric); the isomerism may, however, be an artifact; possibly in the hydrogenation of the 3rd double bond of digitaligenin the added H atoms assume a spatial position different from that which they occupy in anhydrodigitoxigenin. *Addendum.*—Both Cloetta and W. and F. found 183–4° as the m. p. of anhydrodigitoxigenin (VI), while Kiliani gives 215–20°. W. and F. suspected that K.'s product might be contaminated with unchanged digitoxigenin, but examn. of a sample of K.'s product showed that it cannot be converted into the true VI with alc. HCl; it is much more difficultly sol. than VI in $AcOEt$, m. const. 223° after repeated crystn., is shown by color reactions to be free from digitaligenin and is an isomeric β -VI; perhaps it is derived from K.'s hydrated β -I. Toxigenone, obtained by oxidation of VI with CrO_3 , has been repeatedly analyzed by K. who found C 75.81–76.02, H 7.95–8.26, and assigned to it the formula $C_{19}H_{24}O_2$. If in the oxidation only the sec. alc. grouping is oxidized to C:O, the product should have the compn. $C_{19}H_{24}O_2$ (C 78.21, H 8.71%). The low C content, which W. and F. have also regularly obtained in their own analyses, must be due to solvent of crystn. held very firmly; that the compd. still contains 24 C atoms has been proved by its conversion into III. Digitoxigenone, the product of the oxidation of digitoxigenin with CrO_3 , should have the compn. $C_{24}H_{34}O_4$; K. assigned to it the formula $C_{19}H_{26}O_4$, but this is far from being correct; recrystn. of a sample of his material raised the m. p. 14° and the C and H contents 2.3 and 0.7%, resp.

C. A. R.

Saponins. II. *Gypsophila-sapogenin*. P. KARRER AND H. LIER. *Helvetica Chim. Acta* 9, 26–30 (1926); cf. *C. A.* 18, 2711.—When albsapogeninic acid (I) is treated with concd. H_2SO_4 , CO is evolved and when the reaction mixt. is poured on ice a white ppt. (?) is obtained which, after drying and recrystg. from glacial $AcOH$, contains 78.78% C, 9.99% H, mol. wt. 433, and m. 306°. Similarly albsapogenol, gypsophila-sapogenin (II) and albsapin on treatment with concd. H_2SO_4 evolve CO. Reduction of I in glacial $AcOH$ with Zn and HCl, the product being recrystd. from $AcOH$, washed with $EtOH$ and dried, gave a non-acidic compd., $C_{27}H_{44}O_2$ or $C_{27}H_{42}O_2$, m. 314°. II oxidized with CrO_3 in $AcOH$ and then poured into H_2O gave a ppt. (III) which, crystd. from $AcOH$, m. 226°; it is a *monobasic acid*, $C_{26}H_{40}O_6$, mol. wt. 492, and forms a *dioxime*; as the $AcOH$ mother liquors from the oxidation reaction contain several other compds. it is not certain if III is a pure substance.

N. A. LANGE

Remarks on my work "silk fibroin." RUDOLF BRILL. *Ann.* 446, 307–8 (1925); cf. *C. A.* 18, 381.—B. discusses the relation between the compds. obtained by Bergmann (*C. A.* 19, 638) and his X-ray study of silk fibroin.

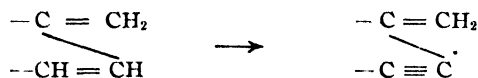

C. J. WEST

Cholesterol. HANS FISCHER AND ALFRED TREIBS. *Ann.* 446, 241–59 (1925).—Cholesterol (I) (5 g.), heated to boiling for 10 min. at 300 mm. and then distd., gives 0.6 g. pseudocholestene, m. 78°, identified as the dibromide, m. 116°, and its dihydro deriv., m. 69–70°, also by a crystallographic examn. of the 3 compds. and comparison with known preps. Attempts to increase the yield by passing HCl into molten I gave the ether of I and α -cholesterylene. Decompn. of I by passing its vapors over a heated Pt wire at 250° (11 mm.) gave about 10% of $C_{10}H_8$, a small amt. of styrene, a *hydrocarbon*, $C_{14}H_{12}$, m. 91–2°, b. about 300°, very volatile with steam, whose dark yellow *picrate*, m. 155°; a *hydrocarbon*, $C_{18}H_{14}$, m. 203°, b_{15} about 200°, not volatile with steam, whose yellow *dibromide*, m. 217°; and a *hydrocarbon*, $C_{14}H_{10}$, m. about 124°, whose orange *picrate*, m. 139°. The gaseous products contained about 5% H, 30% unsatd. and 65% satd. hydrocarbons; traces of C_2H_2 could be detected. When styrene

is heated at 20–30 mm. and 300–40°, there results about 1% of $C_{10}H_8$, distyrene and other compds. of high mol. wt. Similar treatment of 23 g. of the acid $C_{27}H_{44}O_4$ (from I and NaOBr) gave only 0.05 g. $C_{10}H_8$; other definite products could not be isolated. The hydrocarbon $C_{10}H_{18}$ (Mauthner, *Monatsh.* 17, 41(1896)), b. 387°, d. 0.9733, n_D^{20} 1.5317, $[\alpha]_D^{20}$ 54.51°, mol. wt. in boiling $CHCl_3$ normal, gave, on distn. of 33 g. at 60–80 mm. and 300°, only a very small amt. of $C_{10}H_8$ and a compd., m. 252°. The octane-octene mixt. formed in the prepn. of $C_{10}H_{18}$, b. 112–6°, d_4^{20} 0.7065, n_D^{20} 1.3955, contains about 25% satd. hydrocarbon, isolated by shaking with H_2SO_4 contg. 7% SO_3 , b. 113–6°, d_{20} 0.69823, n_D^{20} 1.3922, and is probably *isooctane*. A small amt. of $C_{10}H_8$ is isolated from the decompn. products of cholic acid. Attempts to dehydrogenate I with S, Br-AlBr₃ and I led to no definite products. Since I is reduced to coprosterol in the intestine, it was thought that the catalytic reduction of the oleic ester of I might lead to the same results; the only product was the stearic ester, the I mol. not being reduced. Reduction in tetralin with Ni or Pt gave a little stearic ester, free stearic acid and non-cryst. derivs. of I. Reduction of I under similar conditions gave a poor yield of reduced I ether and a compd. $C_{27}H_{46}O$, m. 133–4°, which is not I. The distn. of the oleic ester of I at 13 mm. gives about 50% of α -cholesterilene.

C. J. WEST

The action of benzoyl peroxide on a dimethylchlorohemin. WILLIAM KÜSTER AND W. RUFF. *Z. physiol. Chem.* 151, 98–113(1926).—An attempt was made to add O. by means of a mild oxidizing agent, to the unsatd. side chains of hemin, in a manner analogous to the oxidation of $CH_2:CHOEt$ to 1:1 glycolide. $(BzO)_2$ in $CHCl_3$ acts upon dimethylchlorohemin, changing entirely the characteristic spectrum of the pigment. About $1/3$ of the hemin is converted into a cryst. substance with a single faint absorption band at $\lambda 635-40$. Instead of the addn. of O it appears from analysis of the product that a removal of 2 H has occurred. The new substance adds 2 Br and shows 2 absorption bands. The Br addn. product when treated with NaOH loses both Cl and Br in an amt. equiv. to the 2 added Br. Replacement of 1 Br by OH gives a cryst. monobromomonomethoxyl deriv. which is easily methylated by CH_3N_2 . It is believed that the dehydrogenation gives an acetylene linkage, thus,

The simultaneous removal of Cl and Br may be accounted for by an exchange of positions of the 2 atoms. The Fe is more easily removed from the dehydrogenation product than from the dimethylhemin, as might be expected from the greater reactivity toward HCl due to the greater unsatn. $PhNH_2$ and pyridine remove Cl less readily, the former 75% and the latter 60% of the amt. present, from the dehydrogenation product. Pyridine produces a change which prevents the replacement of OH by Cl when HCl is added whereas after the $PhNH_2$ treatment the Cl may be restored.

Phenols. V. L. OIL PROCESSES, LTD., O. D. LUCAS and E. L. LOMAX. Brit. 242,092, Nov. 24, 1924. Phenols are extd. from crude oils by use of NaOH or other caustic alkali in a soln. of over 20% strength. The alkali phenolate soln. first obtained is used for further extn. of phenols. On subsequent diln. of the soln. the phenols sep. The partly exhausted soln. is re-concd. and used for treating another quantity of oil. If caustic alkali solns. of over 30% strength are used, the neutral oils which are also taken up by the soln. may be removed by steam distn. before the diln. to sep. phenols

Halogenated alcohols from halogenated aldehydes. H. MEERWEIN. U. S. 1,572,742, Feb. 9. In prepg. a halogenated alc. from the corresponding halogenated aldehyde, *e. g.*, butylchloral, the latter is dissolved in a primary alc., *e. g.*, EtOH, and treated with Al alcoholate.

Condensation products of compound aliphatic-aromatic ketones with polyalcohols. J. ALTWEGG and E. F. CHERMETTE. U. S. 1,572,176, Feb. 9. Compd. ketones, *e. g.*, acetophenone, are caused to react with polyals., *e. g.*, glycerol, in the presence of EtOH or other primary als. contg. small proportions of H_2SO_4 or other inorg. acid, to form condensation products. Acetophenone-glycerol, b_p 134° and may be used to give suppleness to cellulose acetate films.

Catalytic decomposition of ethyl alcohol. K. E. SKAERHLOM. Swed. 60,035, Dec. 29, 1925. An addn. to Swed. 57,583 (C. A. 19, 1430). In the production of C_2H_4 , Et_2O or AcH from alc. the gas mixt. from the catalyzer furnace is passed through a heat-exchanging app. there giving off its excess of heat to the satd. alc. vapor from the alc. boiler.

1,8-Aminonaphtholsulfonic acids. I. GUBELMANN and J. M. TINKER. U. S. 1,573,056, Feb. 16. 1-Naphthylaminesulfonic acids and salts contg. a sulfonic group in the 8-position are fused with caustic alkalies in the presence of NH_3 .

Polymerized styrene and its homologs. I. OSTROMISLENSKY. Brit. 236,891, July 12, 1924. Styrene and its homologs are polymerized by heating to different temps. and for different times to form 3 series of compds. designated as α -, β -, and γ -metastyrenes. Various tough, hard or brittle compds. are described with which dyes, pigments, org. peroxides, $CaCl_2$, nitro compds., quinones, etc. may be mixed to control their properties. Cf. C. A. 20, 424.

Alkyl formates. R. WIETZEL. U. S. 1,572,698, Feb. 9. CO is caused to react on dehydrated MeOH, EtOH or other alc. in liquid form in the presence of NaOMe, NaOEt or other metal alcoholate, under pressure and at temps. of 30–150°.

Naphthophenothiazines, etc. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 236,795, Nov. 7, 1924. Quinonoid derivs. of 2,1-naphthophenothiazines are obtained by reduction of 2-hydroxy-3-(2'-nitrophenylmercapto)-1,4-naphthoquinone or a substitution product and, if necessary, treating with an acid. S dyes may be obtained from this compd. after sulfonation and reduction, which give yellow-green dycings or blue-green on after-chromed wool. Other related reactions are described.

Solid stable diazo compounds. F. GÜNTHER and F. LANGE. U. S. 1,572,715, Feb. 9. Stable solid compds. are obtained by adding $Zn(OH)_2$, $ZnCl_2$ or other compd. of Zn to a soln. of a diazotized aromatic amine which is free from azo groups (thus excluding diazotized amino azo compds.) while taking care that the soln. contains sufficient Cl ions to permit formation of a double compd. of Zn and diazonium chlorides. NaCl may be added to the reaction mixt. The stability of the products may be further increased by the addn. of Na_2SO_4 or other harmless salts.

Chloro derivatives of methane. C. B. CARTER and A. E. COXE. U. S. 1,572,513, Feb. 9. A mixt. comprising $MeCl$, CH_4 and Cl is passed through a reaction chamber maintained at a high temp. (usually about 400–500°) and the $MeCl$ and Cl are maintained in about equal vols., to produce 80% CH_2Cl_2 , 15% $CHCl_3$ and 5% CCl_4 . Cf. C. A. 19, 3272.

Salts of urea from cyanamides. J. BRESLAUER and C. GOUDET. U. S. 1,572,638, Feb. 9. A concd. soln. of free cyanamide is treated with H_2SO_4 and a quantity equiv. to this acid of a salt such as NH_4NO_3 or $Mg(NO_3)_2$ contg. the acid radical of the salt of urea to be prepd. so as to produce the salt directly. Cf. C. A. 20, 97.

A—GENERAL

FRANK P. UNDERHILL

Extractives of muscle: a new iminoazole phosphorus compound. W. D. LANGLEY. *Proc. Soc. Exptl. Biol. Med.* 22, 234(1925).—An unstable phosphoric acid compd. was obtained from muscle. Its empirical formula is $C_{14}H_{21}O_{11}N_4P_4H_2O$. A nearly pure Cu salt resulted from the repeated pptn. from a concd. aq. soln. by alc. It is very hygroscopic and loses 4 mol. of H_2O when heated at 120°. Its only color reaction is that for the iminazole ring; if this is due to carnosine, the org. residue would be $C_6H_6O_6$ which might come from some carbohydrate decompn. product. The substance is

highly unstable and should correlate the chemistry of carnosine and a carbohydrate, and possibly of loosely bound phosphoric acid in muscle. C. V. B.

The influence of protein on the diffusibility of calcium. R. F. LOEB AND E. G. NICHOLS. *Proc. Soc. Exptl. Biol. Med.* 22, 275(1925).—Pure solns. of euglobulin, of pseudoglobulin and of albumin were isolated from ascitic fluid. The presence of these proteins in Ca solns of p_H 6–8 decreased the diffusion of Ca through collodion membranes. Probably Ca proteinate was formed. C. V. B.

Individual blood investigations. IV. The formation of hemins from hemoglobin A and the existence of two hemoglobins Aa and Ab. WILLIAM KÜSTER. *Z. physiol. Chem.* 151, 56–85(1926); cf. C. A. 18, 3065.—Hemoglobin may be regarded as a tribasic complex acid which carries the Fe in the anion. Two of the dissociable H atoms belong to the 2 carboxyls of the globin and the other H to a carboxyl of the prosthetic group. The 2 carboxyls of the prosthetic group are different; hence 2 hemoglobins must exist. In Hb Aa the stronger carboxyl is bound to the prosthetic group, in Hb Ab the weaker. In the isolated prosthetic group quite different linkages prevail as compared to Hb. The isolation of the prosthetic group as hemin is preceded by a transformation of Hb into methemoglobin. This occurs at the moment the prosthetic group goes into soln, i. e., not in the coagulation of the blood but in the extn. with MeOH and H_2SO_4 . In the formation of met-Hb the cation loses 1 H equiv. and the anion becomes bivalent, the OH adding to the Fe to form Fe^{+++} and the H (AcOH method) or the Me (MeOH H_2SO_4 method) to 1 of the carboxyls. Either method can yield 2 transformation forms, according to whether the H adds to the carboxyl of the prosthetic group or to a carboxyl of the globin. Hb Aa and Hb Ab then yield 2 methemoglobins each, of which 2 are identical; hence Hb Aa and Hb Ab can give identical AcOH-hemins. Four forms are possible, 1 of which would have a betaine structure. If the Me enters the carboxyl of the prosthetic group 2 methemoglobins may result from each Hb. All 4 are different. In the cleavage to globin and hemin 8 isomeric mono-methylated hemins may then be formed. If only the globin COOH is methylated an unmethylated hemin results from the cleavage. The product of further methylation is detd. by the form of the monomethylated hemin. Four isomeric dialkylated hemins are possible. The assumption of betaine structures applies also to hematoporphyrin and chlorophyll.

A. W. DOW

Yeast maltase. VI. RICHARD WILLSTÄTTER AND EUGEN BAMANN. *Z. physiol. Chem.* 151, 242–72(1926).—The p_H optimum for yeast maltase is 6.75–7.25; p_H 6.1 is less favorable than neutrality, and p_H 7.5 much more so than 6.1. The kinetics of the reaction on maltose depends to an extraordinary extent on the degree of purity of the enzyme. Yeasts and autolyzates followed in all cases (30–60% hydrolysis) a time-reaction curve which deviates from that of a monomol. reaction. In the form of $Al(OH)_3$ adsorbates and elutions therefrom, however, the enzyme gives a different curve, indicating progressive inhibition during the course of the reaction. This is not due to destruction of enzyme because of its higher purity, since the enzyme is completely protected in the sugar soln. For equal extents of cleavage the product of enzyme amt. and reaction time is const. The phenomenon suggests the removal of some substance which counteracts the inhibition by the glucose formed. The mere filtration of aged autolyzates was sufficient to change the curve from the 1st to the 2nd type, while the reverse occurred when the filtrates were allowed to stand 4–6 hrs. Filtration did not, however, alter the rate of maltase action of a freshly prepd. autolyzate. The behavior of the $Al(OH)_3$ adsorbates is by no means uniform. Some follow the 2nd curve while others deviate from both curves. The detn. of enzyme activity and the comparison of enzyme amts. are more difficult with maltase than with sucrase. All yeast exts. if carefully preserved show an increase in maltase activity. It is possible, therefore, to det. maltase values, but only apparent enzyme amts. A 2nd difficulty is the alteration of the kinetics of the reaction. The use of a cell poison in prepg. the autolyzate results in an acid reaction which is favorable to sucrase but unfavorable to maltase. The method of prepn. is based therefore upon neutralization of this acid after destruction of the cells by EtOAc. It is thus possible to bring the maltase content of the yeast quant. into soln.; EtOAc is preferable to PhMe or $CHCl_3$. After 10–15 min. treatment with EtOAc the liquefied yeast is dild. and neutralized with NH_4OH . One g. of phosphate buffer per 100 cc. enzyme soln. is added, and this maintains a const. p_H in spite of proteolysis. Liquefaction may also be effected by $(NH_4)_2HPO_4$ or NaCl. Ordinary beer yeasts have the power of directly fermenting maltose, without preliminary hydrolysis, through the action of a special component of the zymase complex. The maltose is fermented in so short a time that hydrolysis is negligible. Maltase is even more rapidly liberated and brought into soln. than

sucrase. The EtOAc method with neutralization gives a quant. yield of enzyme soln. contg. only 5–10% of the yeast mass. In working with maltase solns. it is important to keep them at 0°, not merely in an ice box. Maltase is much less stable than sucrase. At 30° the maltase disappears in 1 day, at room temp. in several days but at 0° it may be kept a week. Instead of loss of enzyme there is then an increase in apparent maltase units up to 67%, due probably to alteration or sepn. of inhibitory substances or even to formation of new enzyme from a precursory stage. **VII. Separation of maltase and sucrase.** *Ibid* 273–85.—The view of Michaelis that adsorbents, on account of their acidic or basic properties, act upon enzymes or enzyme complexes of opposite electrochem. nature and thus aid in the sepn. of mixts. is no longer sufficient to explain the differences observed. With an alumina gel of the formula AlO_2H , which does not react appreciably with 38% HCl nor with 4% NaOH, the adsorption is highly selective and cannot be accounted for by the assumption of basic or acidic properties. The AlO_2H is prepd. by the action of NH_4OH on $\text{Al}(\text{OH})_3$ at 250°. In its selective adsorption of maltase it is far superior to fresh or briefly aged $\text{Al}(\text{OH})_3$. With many autolyzates it yields a pure maltase by a single operation of adsorption and elution with $(\text{NH}_4)_2\text{HPO}_4$, while at the same time the sucrase soln. is freed from maltase with very little loss. This selective adsorption may be amplified by a method of selective elution. Both maltase and sucrase are liberated from the $\text{Al}(\text{OH})_3$ adsorbate by faintly alk. phosphate or a phosphate mixt. of p_{H} 6.8. Primary alkali phosphate (KH_2PO_4), however, liberates the sucrase completely and almost exclusively while the maltase alone remains in the adsorbate and can be recovered. The operations should be carried out at 0° to avoid loss of maltase. A. W. Dox

Plant proteases. II. Hydrocyanic acid activation and inhibition of plant proteases. RICHARD WILLSTÄTTER, WOLFGANG GRASSMANN AND OTTO AMBROS. *Z. physiol. Chem.* 151, 289–306 (1926); cf. *C. A.* 18, 3390.—It was previously shown that HCN added to papain has the effect of a kinase. Papain hydrolyzes gelatin though not intensely, but does not hydrolyze peptones. Papain-HCN hydrolyzes gelatin vigorously, and also peptones. Another difference between the enzyme and its cyanohydrin is now reported: the latter hydrolyzes native egg albumin, the former does not. A comparison of plant proteases shows that they comprise tryptic enzymes, of which some are activated by HCN and others inhibited. Bromelin, the protease of pineapple, is similar to papain in this respect, while the protease of the pumpkin differs sharply. For the activation of bromelin H_2S is equally as effective as HCN, but it is somewhat less effective in activating papain. It is not improbable that papain and bromelin are identical and that the lower activation is due in the one case to association with a natural activator. Pumpkin protease is decidedly inhibited by HCN and still more so by H_2S . It acts upon gelatin best in faintly alk. medium and on peptone at p_{H} 6.3. It is easily adsorbed from faintly acid soln. by $\text{Al}(\text{OH})_3$, while papain is adsorbed only from slightly ammoniacal soln. It acts with difficulty on gelatin but readily on fibrin, thus differing from papain-HCN. Both enzymes, however, are analogous to trypsin + enterokinase. **III. Substrate and activity optimum in some proteolytic reactions.** *Ibid* 307–17.—Papain, with or without HCN activator, shows an optimum for gelatin cleavage which coincides approx. with the isoelec. point of the substrate, *viz.*, p_{H} 5.0. Other substrates were tested in order to det. whether the enzyme is adjusted to the undissoc. proteins. In the hydrolysis of albumin peptone the max. cleavage (p_{H} 5.0–5.2) is approx. at the isoelec. point (4.8), and with blood fibrin the activated enzyme gives a sharp optimum at p_{H} 7.1–7.3 (isoelec. point 7.2). Thus the reaction optima with papain coincide with the isoelec. points of the substrates. Bromelin gives an optimum cleavage of gelatin at p_{H} 4.5–5.0, and of albumin peptone at p_{H} 5.0. Pumpkin protease behaves quite differently. The optimum p_{H} for cleavage of peptone is at 6.3, and for gelatin at slight alk. For fibrin the optimum of this enzyme is practically the same as that for papain. Pumpkin protease is evidently a different type of protease from papain and bromelin. A. W. Dox

Spectrochemical investigations on porphyrins and hematin. I. The identification of coproporphyrin and the significance of spectrochemical methods for porphyrin and porphyratin investigation. II. The hematin occurring in the blood serum of sick persons. O. SCHUMM. *Z. physiol. Chem.* 152, 1–17 (1926).—The difficulty of distinguishing between coproporphyrin and Nencki's hematoporphyrin when only small amts. of material are available may be overcome by the use of concd. H_2SO_4 as a solvent. Pure hematoporphyrin in concd. H_2SO_4 shows the main absorption band 5μ nearer the red than the corresponding band of coproporphyrin under the same conditions. In 25% HCl the difference is only half as great. This method serves also to distinguish Nencki's hematoporphyrin from Zaleski's mesoporphyrin, Willstätter's hemoporphyrin

and the author's coproporphyrin, but not from α -porphyrin or uroporphyrin. Hematoporphyrin and uroporphyrin, however, are readily distinguished after treatment with Br. A systematic scheme is outlined by which the identification of a porphyrin may be performed, and certain precautions in technic and the use of app. are recommended. The hematin occurring in the serum of patients having pernicious anemia or hematoporphyrin has been more conclusively identified as α -hematin.

A. W. DOX

Röntgenographic studies on chitin. H. A. GONELL. *Z. physiol. Chem.* **152**, 18-30 (1926).—Thirteen diff. chitin preps. from animal and plant sources were examd by the X-ray method. Of these 11 contained the same crystd. substance. The differences were merely in arrangement and size of the crystallites and in the content of amorphous substance. In the interpretation of the diagrams it was concluded that the elementary substance contains 18 acetylglucosamine anhydride mols., of which 1, 2, 3, 6 or all contained in 1 crystallite may form a group.

A. W. DOX

Specific dynamic action. E. AUBEL. *Ann. physiol. physicochim. biol.* **1**, 31-46 (1925); *Physiol. Abstracts* **10**, 173.—Sp. dynamic action (Rubner) is explained on the hypothesis that an endothermic reaction can only occur to the accompaniment of an associated reaction capable of furnishing the energy necessary for the first. Food substances may give rise to sp. dynamic action even in case of their not being converted to glucose.

H. G.

Surface tension in biology. VIII. The surface tension of some substances used in medicine. W. KOPACZEWSKI, M. BEM AND G. DE CASTRO. *Arch. intern. pharmacodynamie* **29**, 69-83 (1924); *Physiol. Abstracts* **10**, 140; cf. *C. A.* **18**, 3605.—Observations of the effects produced on surface tension by numerous substances are tabulated. Plant and animal preps. in use do not represent from this point of view the active principles to which their utility is ascribed—e. g., liver exts. have a high surface tension, while it is well known that their "active principle" lowers it. It is suggested that emetics, purgatives, etc., may owe their activity to the increase of surface tension of human serum which they produce.

H. G.

Influence of innervation on the creatine content of muscles. D. G. C. TERVAERT AND J. G. DUSSEER DE BARENNE. *Arch. néerland. physiol.* **9**, 392-4 (1924); *Physiol. Abstracts* **10**, 151; cf. *C. A.* **17**, 816.—The amt. of decerebrate rigidity in the leg muscles of 1 side was varied by stimulation of the peroneal nerve on the same and opposite sides. The muscles of the opposite limb were removed before decerebration to act as a control. More creatine was invariably found in the excited rigid muscles than in those of the control side.

H. G.

Desensitization of the heart for β -rays. G. J. VAN DEN BOVENKAMP. *Onderzoek. Physiol. Lab. Utrecht* **5**, 119-35 (1925); *Physiol. Abstracts* **10**, 154.—Frog's hearts were brought to a standstill by perfusing with Ringer to which U had been added just to balance the K. The radioactive effects of U are due to positive α -rays, while the effects of K are due to negative β -rays. On adding to the fluid different cytolytic substances such as mono-basic fatty acids, alcs., blood serum and certain alkaloids, the radio-physiol. equil. is shifted to the α -side. This effect is due to the desensitization of the heart for β -rays. Rabbit serum heated to 36° behaves as unheated serum towards this shifting. Cu, Ag and Au oligodynamic doses produce the same shift of equil. and desensitization of the heart for the β -rays of K.

H. G.

α -Rays and heart action. J. N. VOORSTAD. *Onderzoek. Physiol. Lab. Utrecht* **5**, 151-69 (1925); *Physiol. Abstracts* **10**, 154.—A galvanoplastic ppt. of Po on Cu can act as an α -radiator, and can stimulate a heart to beat which has been previously brought to a standstill by removing the K. External α -radiation and internal β -radiation cause stoppage; similarly with the reverse application. External and internal α -radiation are additive unless the maximal dosage is exceeded. Perfusion with Ringer contg. emanation gives more const. results than external α -radiation. The action of α -ray cannot be explained chemically. β -Radiators produce paradoxa and equilibria under the above conditions.

H. G.

Note on the penetration of hydroxyl ions into gelatin jellies. J. GRAY. *Proc. Cambridge Phil. Soc. Biol. Sect.* **1**, 237 (1925); *Physiol. Abstracts* **10**, 207.—Expts. on the penetration of ions into gelatin jellies show that a differential permeability to weak and strong alkalis is no proof of the presence of a fatty substance in the membrane in question. The suggestion is made that Mg and Ca are necessary to the living cell because they form some intracellular ppt. having the properties of a membrane.

H. G.

The origin of the potential differences between the interior and exterior of cells. J. B. S. HALDANE. *Proc. Cambridge Phil. Soc. Biol. Sect.* **1**, 243 (1925); *Physiol. Ab-*

tracts 10, 206.—“The observed facts as to the permeability of cells to electrolytes account quantitatively for the injury potentials and H-ion concns. of tissues. These can be calcd. from their Cl and H₂O contents.”

H. G.

Physical chemistry of the globulins. VII. The behavior of acid and alkali globulins on the addition of salts. MONA ADOLF. *Kolloidchem. Beihefte* 21, 241–81(1926); cf. *C. A.* 19, 1285.—The addn. of salts to acid solns. of globulins causes a decrease in the H ion, though in no case was complete neutralization effected. This action increases with increasing valency of the anion and decreasing valency of the cation. Alkali-globulin solns. may likewise be rendered acidic by the addn. of salts. The *cond.* of solns. of acid or alkali globulins contg. salts is less than the sum of the conds. of the constituents. This diminution is only partially due to the change in H ion and free charge on the globulin ion. It is dependent on the concn. of the salt added. The *viscosity* of acid-globulin solns. decreases on the addn. of neutral salts, approaching a const. value. The *migration velocity* of the protein ion also diminished, vanishing *e. g.*, on the addn. of 0.2 N KCl to globulin chloride. The action of the salt on the protein ion increases with increasing valency of the salt ion of opposite charge. Bivalent and trivalent ions may thus reverse the direction of migration. The Cl ion of neutral Na globulinate solns. in the presence of various chlorides was detd. The increase in the Cl ion on shaking with Hg₂Cl₂ is attributed to the formation of a complex.

ARTHUR GROLLMAN

Teaching of biochemistry. C. J. FARMER. *Proc. Assoc. Am. Med. Colleges* 36, 95–102(1925).—Stress is placed on the related phys. chemistry and on precise quant. rather than qual. expts.

JOSEPH S. HEPBURN

Chlorocruorin: a pigment allied to hemoglobin. H. M. FOX. *Proc. Roy. Soc. (London)* 99B, 199–220(1926).—The blood plasma of certain polychete worms contains chlorocruorin, a pigment, in soln. The concd. soln. is red, the dil. soln. green. Chlorocruorin exists in an oxidized form and a reduced form; these forms are characterized by adsorption spectra; the absorption bands resemble those of oxyhemoglobin and reduced hemoglobin, but are nearer the red end of the spectrum. Oxychlorocruorin is reduced by a vacuum or by living tissue; air reoxidizes the reduced form. Chlorocruorin has less affinity for O₂ than has hemoglobin; its affinity is increased by an increase in *p*_H. The sp. chlorocruorins differ in affinity for O₂, the affinity being greatest in *Myxicola*, and decreasing in *Spirographis*, *Sabella*, and *Branchiomma* in that relative order. In an atm. of O₂ at atm. pressure, the chlorocruorin of *Myxicola* is satd. with O₂, while the chlorocruorins of the other 3 species are unsatd. The blood of *Spirographis* has a total O₂ capacity of 9.1 vol. % in air and 10.2 vol. % in O₂. The absorption spectrum of oxychlorocruorin is characterized by a high value of the absorption ratio α/β , a low value of the absorption ratio γ/γ' and the presence of an extra small band in the visible region between β and γ ; the wave length of the α band axis varies with the species. The Stokes band, produced by reduction with hyposulfite, has a summit with a buttress on either side and thereby differs from the bands yielded by mammalian and Arenicolan hemoglobin. Chlorocruorin has a greater affinity for CO than for O₂. Light dissociates CO-chlorocruorin more readily than CO-hemoglobin. Metachlorocruorin has a spectrum which differs considerably from that of methemoglobin. Chlorocruorohematin, in both acid and alk. aq. soln., has characteristic spectra, unlike those of hematin under the same conditions; dissolved in a mixt. of Et₂O and glacial AcOH, it yields a spectrum similar to that of hematin in the same solvent, but with the bands moved toward the red. Chlorocruorochromogen closely resembles hemochromogen spectroscopically, but its bands are nearer the red and do not attain their final position immediately after prepn. The chlorocruorochromogens of all species have the axis of the α band at the same wave length. The α band of NH₂-chlorocruorochromogen has a position different from that of the same band of the NH₂ compds. of hemoglobin, heliocorubin and actinohematin; therefore, the hematin of chlorocruorin is not the same as that of these other pigments. The hematin group of chlorocruorin contains Fe which is united to a porphyrin. This porphyrin differs from hematoporphyrin, having a similar spectrum but with bands shifted toward the red; it is sol. in CHCl₃.

JOSEPH S. HEPBURN

The biologic action of urea. O. WELTMANN AND A. GOTZMANN. *Z. ges. expl. Med.* 47, 369–85(1925).—The resistance of different urines to infection with nitrite-forming bacteria depends only partly on different *p*_H values and is independent of the concn. In heated urine nitrite-forming bacteria form less nitrite than in unheated urine and the substance in the urine changed by heating is probably urea. Heated solns. of urea inhibit the action of nitrite-forming bacteria, probably by inhibiting the growth of the bacteria and by weakening their reducing power. NH₄ cyanate is prob-

ably the biologic active principle in a heated soln. of urea. Solns. of urea on standing at incubator temp. are probably converted to NH_4 cyanate, and show the same power of inhibiting nitrite formation. K cyanate has a similar action in inhibiting nitrite formation. Whether NH_4 cyanate plays a role in human pathology must be left at present as an open question.

HARRIET F. HOLMES

A contribution to the knowledge of the lipases of the blood. V. JEDLIČKA. *Z. ges. expl. Med.* 47, 534-41(1925).—Serum lipase is not adsorbed by cholesterol or its palmitic acid ester. Pancreatic lipase is adsorbed by cholesterol and by its palmitic acid ester. Pancreatic lipase is adsorbed by cholesterol palmitate only in a protein-free medium and by cholesterol also in a protein-contg. medium as serum. That pancreatic lipase is not inhibited in action in serum is probably due to the fact that the cholesterol is present in the form of a cholesterol ester. The inhibition of the action of pancreatic lipase by the stroma of erythrocytes is probably due to the fact that the cholesterol in the erythrocytes is present as free cholesterol and not as a cholesterol ester. Serum lipase differs from pancreatic lipase not only by a different behavior with atoxyl but also by physico-chem. characteristics as indicated by cholesterol adsorption tests.

HARRIET F. HOLMES

The causes of animal pigmentation. X. The role of dopa in the cocoons of some moths and wasps and notes on the chemical site of melanin formation. HANS PRZIBRAM. *Arch. mikroskop. Anal. Entwicklungsmech.* 102, 624-34; *Ber. ges. Physiol. expl. Pharmakol.* 29, 353.—Expts. with the cocoons of *Cimbex* and *Lophyrus* confirmed P.'s findings on *Eriogaster* and *Saturnia* that melanin is formed by the action of H_2O on dopa (*dihydroxyphenylalanine*). The pigmentation of the cocoons can, therefore, be considered as "protective pigmentation." Dopa was never observed as an intermediate in the formation of melanin from tyrosine. The point of attack of the enzymic, photo-sensitive tyrosinase action is very likely in the side chain, since the reaction is common to dopa and tyrosine, but is unknown in pyrocatechol.

MARY JACOBSEN

The nature of photoactivity. THEO BRANDESS. *Fortschr. a. d. Geb. d. Röntgenstr.* 32, 352-6(1924); *Ber. ges. Physiol. expl. Pharmakol.* 29, 331.—The so-called photoactivity is a purely chem. action on the plate. There is no proof of a light action.

MARY JACOBSEN

Vital tissue staining under the influence of Röntgen rays. CARL HOLTERMANN. *Strahlentherapie* 17, 158-74(1924). **The influence of Röntgen and Radium rays on vital stains.** *Ibid* 362-5; *Ber. ges. Physiol. expl. Pharmakol.* 29, 532-3.—Vital staining with trypan blue (1%) and lithion carmine (5%) in white mice is subject to great variations, the kidney alone presenting certain regularities. With trypan blue the glomeruli present a picture characteristic for the increase of stain fixation. Double staining (trypan blue and lithion carmine) produces about the same picture as Röntgen irradiation alone. The different degree of fixation in the various areas of the upper capillary system is accentuated by Röntgen irradiation. The characteristic effect appears even if the organ stained has not been directly irradiated (irradiation of the head only). While the kidney glomerulus does not fix lithion carmine, the spleen follicle takes both dyes. Gravid animals fix the dyes only with difficulty or not at all. Placenta and membranes remain impermeable even under the influence of Röntgen rays. Different vital stains behave differently. There is additivity of the lesions produced by irradiation and dye. The changes occurring in vital staining are of a general, not local nature. Ra does not produce most of the characteristic Röntgen effects but the sensitization to the stain is considerably higher. Possibly the differences between the biol. effects of Ra and Röntgen rays are based on the dominance of either general or local effects.

Present status of our knowledge of the constitution of the coloring matter of blood. COSTIN NENITZESCO. *Bul. soc. chim. România* 7, 102-16(1925).—An address.

A. PAPINEAU-COUTURE

The electric capacity of suspensions with special reference to blood. H. FRICKE. *J. Gen. Physiol.* 9, 137-52(1925).—The sp. capacity of a suspension is defined as that capacity, which combined in parallel with a certain resistance, electrically balances 1 cm. cube of the suspension. The sp. capacity of a suspension of spheroids is expressed

by the formula, (1): $C = C_0 \alpha g(1-r_1)/r$, where C is the sp. capacity of the suspension, C_0 the static capacity of 1 sq. cm. of spheroid membrane, r and r_1 are the sp. resistances, resp., of suspension and suspending liquid, $2g$ the major axis of spheroid and α a const. previously derived (cf. Fricke, *Phys. Rev.* 26, 678(1925)). The formula, (2), $C = C_{100}(1-r_1)/r$, holds for practically any suspension regardless of the form of the particles. C_{100} is the sp. capacity of a suspension with a concn. of 100%. Both formulas hold only when the frequency is so low that the impedance of the static capacity of the membrane surrounding a single particle is high as compared with the resistance of the interior of the particle. They also hold for suspensions of homogeneous particles when polarization takes place at the surface of each particle provided the polarization resistance is low as compared with the impedance of polarization capacity. A method is given for measuring the capacities of suspensions between 800 and 4.5 million cycles. Measurements of the capacity of suspensions of red blood corpuscles of the dog showed that formula (2) is correct and that C_0 is independent of frequencies up to 4.5 million cycles and independent of the suspending liquid. This furnishes further evidence for the theory that C_0 represents the static capacity of the corpuscle membrane. From these data, the thickness of the corpuscle membrane is found to be 3.3×10^{-7} cm. A discussion of the polarization of electrodes is included. CHAS. H. RICHARDSON

The electric resistance and capacity of blood for frequencies between 800 and 4.5 million cycles. H. FRICKE AND S. MORSE. *J. Gen. Physiol.* 9, 153-67(1925).—A formula is derived for the sp. resistance of red corpuscles and serum. Calves' blood was used. CHAS. H. RICHARDSON

Some general properties of proteins. M. L. ANSON AND A. E. MIRSKY. *J. Gen. Physiol.* 9, 169-79(1925).—The processes of denaturation and coagulation of hemoglobin resemble those of other proteins. When proteins are denatured they are probably polymerized. Hemoglobin is probably depolymerized into hemochromogen. Native proteins can be regarded as aggregates of denatured proteins. Globins and histones should be regarded as denatured proteins rather than a distinct group of proteins. The denaturation of proteins is a reversible process but the flocculation of the denatured protein makes it appear to be irreversible. When proteins are denatured a non-polar group is uncovered. The 2 most sensitive tests for the specificity of proteins (absorption spectra and precipitin reactions) show that proteins are highly sp. only when they are in the native form. No new exptl. data are offered. There is a bibliography of 22 titles. CHAS. H. RICHARDSON

The effect of radioactive radiations and X-rays on enzymes. IV. The effect of radiations on solutions of invertase. R. G. HUSSEY AND W. R. THOMPSON. *J. Gen. Physiol.* 9, 211-5(1925).—The inactivation of invertase by β radiation is explained quantitatively in the same manner previously stated for pepsin and trypsin (cf. C. A. 17, 2590, 3681). C. H. R.

The effect of radiations from a mercury arc in quartz on enzymes. I. The effect of ultra-violet radiation on pepsin in solution. R. G. HUSSEY AND W. R. THOMPSON. *J. Gen. Physiol.* 9, 217-9(1925).—"Pepsin in soln. is inactivated by the radiations from a Hg arc in quartz. It would seem that the effective radiations are those in the ultra-violet region of the spectrum. The form of the curve describing the course of the inactivation is the same as that found for monomol. chem. change." C. H. R.

Formation of complexes between proteins and hydroxides of trivalent metals. Method of desalbumination by the alums. L. C. MAILLARD AND W. WUNSCHENDORFF. *Compt. rend.* 181, 941-2(1925).—Hydroxides of Al, Cr and Fe were studied. Two cc. of serum, 5 cc. H_2O and 25 cc. of 5% ordinary K alum are well mixed and 10 cc. of 0.5 N NaOH and 0.5 cc. of bromothymol (2 in 1000) are added. The NaOH is then added drop by drop until the liquid is yellowish orange. The mixt. is then filtered. The filtrate is colorless; its p_H is 7.0; it is entirely free from proteins and practically free from Al. The complex ppt. of serum and alum under these conditions does not absorb NH_4 salts, urea or uric acid when added to the mixt. L. W. RIGGS

Mineral elements associated with oxyhemoglobin in horse blood. A. DESGREZ AND J. MEUNIER. *Compt. rend.* 181, 1029-31(1925).—Following the first crystn. of hemoglobin the elements K, Na, Ca, Li and slight traces of Mn are found to be fixed in its mol. The spectrum shows K to be present in much the largest amt. A second crystn. diminishes the proportion of K without causing a sensible variation in Ca. The desiccation in the air of the product of the second crystn. transforms the pigment into 2 forms, one sol. free of Li and retaining Ca, the other insol. having fixed apparently all of the Li. K does not reappear in either of these portions. L. W. R.

Physicochemical properties of certain constituents of the serum. F. VLES AND A. DECLOUON. *Compt. rend.* 181, 1189-91(1925); cf. C. A. 18, 3067; 19, 3312.—A

further study of the displacement of the isoelec. point of normal and pathologic serums is reported.

L. W. RIGGS

Physiologic action of ultra-violet rays transmitted by the thin glasses in common use. J. RISLER AND FOVEAU DE COURMELLES. *Compt. rend.* 182, 173-4 (1926).—The skin injury caused by ultra-violet rays was tested under various conditions. The max. sp. action appears to be from rays of the length 2960-3050 Å. U. **Remarks on the preceding communication.** DANIEL BERTHELOT. *Ibid.* 175.—The findings of Risler and deCourmelles confirm the observations of Foucault in 1843. It is noted that at high altitudes the solar rays produce erythema with those unaccustomed to living at such altitudes.

L. W. RIGGS

Relationship between the albumins of different organs. KAKUZO SAKURABAYASHI. *Tohoku J. Exptl. Med.* 6, 427-9 (1925).—An intimate biological relation appears to exist between the albumins of the liver and kidney; but between the lungs and the spleen or between these and other organs no such biologic relation was found. Both normal and immunized serums react so definitely upon the antigens and anti-serums that their biological behavior is known. The liver and kidney have a common antigen

Methods in which viscosity data are combined with refractometric data are studied.

F. A. CAJORI

Determination of chlorine in small amounts of tissue. E. URBACH AND P. FANTL. *Wiener klin. Wochschr.* 38, 384-5 (1925).

E. J. C.

The occurrence of copratin and the identification of blood in feces. O. SCHUMM. *Z. physiol. Chem.* 151, 126-9 (1926).—Bile usually gives the pyridine-hemochromogen reaction which may be due to traces of α -hematin from contamination with blood. Copratin was not found. In the meconium copratin is found in about 1 case out of 20, while the pyridine-hemochromogen test is always positive. When a small amt. of blood enters the digestive tract, e. g., from occult bleeding, it is occasionally observed that the feces show the copratin spectrum in the $CHCl_3$ ext. when the hemochromogen test is negative. The benzidine test is too sensitive to be conclusive, except that a negative test is positive evidence of the absence of hematin. Thus far no food

plant has been found to contain copratin; hence the copratin test is more sp. than the hemochromogen test.

A. W. DOX

Determination of small amounts of lead in animal tissues. ROKURO NAKASEKO AND ISAMU NAKANO. *Kyoto Med. J.* Aug. 1925.—After the destruction of org. matter by concd. HNO_3 , concd. HNO_3 and H_2SO_4 or ashing, dissolve in HNO_3 , neutralize with NH_4OH and make 0.1 N with HNO_3 . Sat. with H_2S , filter, dissolve the ppt. in HNO_3 , neutralize with NH_4OH , acidulate with AcOH and ppt. with 1 drop of 10% K_2CrO_4 . Filter and treat the ppt. with 1 cc. 6 N HCl , 1 cc. of 5% KI and 1 cc. of starch. After 1 minute titrate with 0.001 N $\text{Na}_2\text{S}_2\text{O}_3$. From 2 N HNO_3 Pb can also be deposited as PbO_2 by a current of 0.05 ampere at 0.5 volt and the ppt. dissolved in 5 cc. of 5% KI and 1 cc. of AcOH . The soln. can then be titrated with thiosulfate.

W. T. H.

Phenolphthalol, its preparation and reaction toward oxidases and peroxidases. G. D. BUCKNER. *Am. J. Physiol.* 74, 354-8(1925).—Phenolphthalol was prepd. by the modified method of Baeyer. It is a sensitive reagent for oxidases and peroxidases but has no advantage over phenolphthalin. Human blood can be detected in a diln. of 5×10^{-6} . It is excreted unaltered after abdominal injection into the guinea pig or *Tapes decussatus*. Neither the blood nor the fresh or dried tissues of the latter gave an oxidase reaction, except the abdominal organs and their contents.

M. J.

The miostagmin reaction of malignant tumors. M. ASCOLI. *Ergebn. inn. Med. Kinderheilk.* 25, 944-87(1924); *Ber. ges. Physiol. explil. Pharmacol.* 29, 385.—Comprehensive review and detailed technic.

MARY JACOBSEN

Experiences concerning cholecystography. MAX EINHORN, W. H. STEWART AND E. J. RYAN. *Arch. Verdauung-krankh.* 36, 245-62(1926).—Graham's method of cholecystography has great diagnostic value. The intravenous injection of tetrabromophenolphthalein is often accompanied by reactions. In contrast to this tetraiodophenolphthalein is harmless in large doses. The latter is, therefore, to be preferred.

FRANCES KRASNOW

A new use for phosphotungstic and phosphomolybdic acids in the determination of uric acid in milk and blood. G. REIF. *Biochem. Z.* 161, 128-38(1925).—The blue color which appears in certain solns. of phosphotungstic acid is due to the presence of traces of molybdic acid. A soln. contg. 3.0 g. Na tungstate, 2.0 g. Na_3PO_4 , 0.05 g. MoO_3 and 25 g. H_2O is proposed as a uric acid reagent. The mixt. is warmed, and then neutralized to litmus with HNO_3 . It keeps indefinitely. In the detn. 10 cc. of unknown are treated with 0.5 cc. of 10% HCl and 1 cc. of reagent. The mixt. is quickly heated to boiling and then allowed to stand. Those substances in blood which interfere with the uric acid detn. may be extd. with CHCl_3 .

W. D. L.

Iron in nutrition. II. Quantitative methods for the determination of iron in biological materials. C. A. ELVEHJEM AND E. B. HART. *J. Biol. Chem.* 67, 43-51(1926).—Thompson's method (*J. Chem. Soc.* 48, 493) for the detn. of Fe may be used for materials relatively high in Fe and low in P. Walker's modification (*C. A.* 19, 2613) is satisfactory for materials somewhat rich in P. A new method is described for substances relatively low in Fe and high in P such as milk. The phosphate which interferes with the permanence of the color developed with KSCN is removed by pptn. with $(\text{NH}_4)_2\text{MoO}_4$, the Fe is then pptd. with KOH and the $\text{Fe}(\text{OH})_3$ dissolved in HCl and detd. colorimetrically.

A. P. LOTHROP

The quantitative determination of dihydroxyacetone. W. R. CAMPBELL. *J. Biol. Chem.* 67, 59-69(1926).—Dihydroxyacetone reduces boiling acid phosphate molybdate solns. directly while the reduction from an equal amt. of pure glucose is about $1/180$ as great. A colorimetric method is described and also a volumetric one which is considered preferable and in which the blue soln. is reoxidized by KMnO_4 . An empirical correction is made for the glucose and other reducing substances in the Folin-Wu blood filtrate. Examn. of several hundred samples of human blood failed to show any considerable amt. of dihydroxyacetone normally present in the blood. It is proposed to apply the method to the study of the metabolism of this substance.

A. P. LOTHROP

The tryptophan content of the important proteins found in foodstuffs and a new procedure for determining tryptophan. J. TILLMANS AND A. ALT. *Biochem. Z.* 164, 135-162(1925).—The Fürth-Nobel method for detg. tryptophan is unreliable as a quant. procedure, because pure tryptophan solns. yield a blue-violet, while protein solns. contg. tryptophan give a red-violet color, so that the direct color comparison is impossible. The tryptophan content of protein, even when the inequality of coloration is compensated by the use of proper glass filters, is too high. The methods of May and Rose and Folin and Looney have been found satisfactory but time consuming and difficult to carry out. The new method is based upon the reaction of protein with

formol and H_2SO_4 . This permits a direct detn. of the tryptophan in protein without the need of preliminary hydrolysis and at the same time the color produced is the same with pure tryptophan solns. as well as with protein. The yellow color reaction is obtained when the tryptophan-contg. material is treated with a little HCHO , then with an excess of 66% H_2SO_4 . The reaction is not given by any other known component of the protein mol. It is sensitive to at least 0.1 mg. tryptophan and the max. color develops in about 10 min. and remains unchanged for a considerable time. The best results are obtained with a single drop of a 2% HCHO soln.; the optimum concn. of the H_2SO_4 is 66–67% (by wt.). The H_2SO_4 must not be less than 60 nor more than 70%. Examd. by this method, human milk proteins show a higher tryptophan content than those of either cow or goat milk. The tryptophan content of cheese is not affected by the ripening process. Incidentally, it was found that the Fritzmann reaction for nitrates in milk is a specific tryptophan reaction. The tryptophan content of myosin from meat of various animals varies very little and the expectation that a method may be devised based upon the tryptophan reaction for differentiating between horse meat and beef was not realized. The tryptophan content of wheat protein is generally higher than that of oats, but the differences are not large enough to make a chem. differentiation possible. It was possible, however, to demonstrate that both of these vegetable proteins are made up of 4 distinct components. It has also been corroborated that zein lacks tryptophan and it is possible to detect adulteration of wheat flour with corn meal, since the tryptophan content of the alc.-sol. proteins of wheat flour should not be below 0.8%. The tryptophan content of various other cereals as well as legumes is not materially different from that of wheat or oats.

S. MORGULIS

A colorimetric micro-method for the determination of lactic acid in blood. BRUNO MENDEL AND INGEBORG GOLDSCHIEDER. *Biochem. Z.* 164, 163–74 (1925).—See C. A. 19, 3504.

S. MORGULIS

Phosphorus determination in small quantities of substance. KURT SAMSON. *Biochem. Z.* 164, 288–94 (1925).—The inorg. P in serum deproteinized with CCl_3COOH is pptd. with NH_4 molybdate, HNO_3 and NH_4NO_3 . The ppt. is removed by centrifuging and after washing is dissolved in NaOH . One cc. of $N/25$ NaOH corresponds to 0.0478 mg. P. Ppt. 0.5–1.0 cc. serum with 1 cc. 20% CCl_3COOH and after 10 min. centrifuge. Transfer the fluid to another tube, add 1 cc. of the acid to the ppt. and once more centrifuge. Ash the ppt. and dissolve in 0.5 cc. of 10% HNO_3 . To the soln. contg. the P add 1 cc. of 30% NH_4NO_3 soln., 0.4 cc. concd HNO_3 and 1 cc. 3% $(\text{NH}_4)_2\text{MoO}_4$ soln. with proper attention to thorough mixing. Place the tubes for 2–3 min. in boiling water until a definite yellowish green ppt. is formed. After complete cooling add 1 cc. abs. alc., which aids in settling the ppt. to the bottom, and centrifuge. Wash the ppt. 3–4 times with 1% KNO_3 soln., add abs. alc. and centrifuge. Repeat the washing until a drop of the fluid no longer reddens blue litmus paper. Dissolve the ppt. completely in $N/25$ NaOH and titrate the excess alkali with $N/25$ HCl using phenolphthalein. Microburets are used for the titration.

S. MORGULIS

A new method for the determination of cystine in protein (the iodine method). YUZURU OKUDA. *J. Biochem. (Japan)* 5, 217–27 (1925).—The principle of the method is the reaction of cystine with I after treatment with nascent H. Cystine alone among the amino acids reacts in this way, and therefore this procedure can be utilized for detg. the sum of cystine and cysteine. The reagents required are the same as those given in the cysteine method, but the KIO_3 soln. is standardized against a cystine soln. Dissolve 1.01 g. cystine in 50 cc. of about 5% HCl and add a few decigrams of zinc dust. Allow the reduction to proceed at room temp. for 30 min., shaking from time to time. Filter, wash and make up to 100 cc. with H_2O . Transfer 1 cc. of the fresh filtrate to a clean dry flask or test tube and mix with 19 cc. of an exactly 2% HCl soln., then add 55 cc. each of 5% KI and 4% HCl , and titrate with KIO_3 soln. until a permanent yellow color is produced. Take the temp. of the titration mixt. immediately upon completion of the reaction. Since the vol. of KIO_3 required varies with temp. 1-cc. portions (0.0101 g. cystine) should be titrated at several temps. and the results plotted in the form of a curve, from which the amt. necessary for any temp. can be read off directly. For detg. the cystine in protein 1–10 g. of the substance is boiled with 3 times its vol. of concd. HCl under a reflux condenser at first over a water bath, and later for 20 hrs. over a sand bath. Evap. under reduced pressure to remove all HCl , add a little H_2O and decolorize by heating for 30 min. with charcoal. To the cool filtrate add a little Zn dust and reduce at room temp. for 30 min., filter and make up to 100 cc. One-cc. portions are titrated to det. the concn. of the HCl , and the residual soln. is adjusted so that it contains exactly 2% HCl . Take a measured amt. of this soln. and make the vol. to 20 cc. with 2% HCl , then add the other reagents and titrate with KIO_3 as

before. If the original material contained both cysteine and cystine the former must be detd. separately, and the cystine calcd. from the difference between the total and free cysteine. Accurate results are obtained if the analyses are carried out under strictly comparable conditions of acid concn., cysteine concn., temp., etc. S. M.

Detection of carbon monoxide in the autopsy of corpses in an advanced stage of putrefaction. ETIENNE MARTIN. *Ann. méd. légale* 1, 20-3(1921).—CO which has caused death can be detected in the putrid exudations of cadavers. Even when there remains no blood in the heart and in the vessels, the putrid exudations which are present between the pleuras should be tested for CO. Spectral reactions and the 2.5% tannin soln. reaction have given positive results as much as 3 months after death. A. P.-C.

New process for the detection of sperm stains in medico-legal investigations. PELISSIER AND CORDONNIER. *Ann. méd. légale* 1, 64-8(1921).—The following technic is recommended for the detection of sperm in stains on fabrics: immerse about 0.25 sq. cm. of the fabric in 5% CH_2O for 24 hrs., wash, immerse 1 hr. in a 1:1 alc. (95%)—pyridine mixt., wash, immerse 6 hrs. in 3% AgNO_3 at 50° (with dense materials, e. g., wood, leave 12-24 hrs.), wash, reduce 6-7 hrs. in either (A) H_2O 100, formalin 5, pyrogallol acid 4, pyridine 8, or (B) H_2O 100, hydroquinol 1.6, Na_2SO_3 10, pyridine 8, wash in running water for 30 min., and let stand in distd. H_2O contg. a few drops of CH_2O . To mount, place a thread on the microscope slide in a drop of distd. H_2O , tease apart with a needle, evap. at moderate temp., add Canada balsam and cover. If a ppt. has formed during prepn remove by immersing in concd. NaOCl or $\text{Na}_2\text{S}_2\text{O}_3$ — Na_2SO_3 soln before mounting. If the spermatozoa have been bleached by the latter treatment, they can be intensified by treating 5 min. with 2% Au or Pt chloride soln. The fibers are practically colorless and the spermatozoa stand out as blackish brown, the head and tail being of different intensities owing to differences in the density of the protoplasm. The method has been tried out successfully on stains of known origin on silk, cotton, wool, burlap, linen which had been trampled and exposed to rain for several days, linen which had been heated to 80° , tissue paper, newspaper and wood shavings. A magnification of 250 diams. is amply sufficient for the examn. The advantages of this method of prepn. over the usual ammoniacal crythrosin method are discussed. When properly mounted the slide will keep practically indefinitely. A. P.-C.

Medico-legal examination of stains of fecal matters. HAZIME ASADA AND MATA-CHIRO KOMINAMI. *Ann. méd. légale* 2, 92-4(1922).—The stercobilin test can be applied to clothes stained with fecal matter as follows: if the stain is quite yellow, moisten with distd. H_2O , apply a piece of moistened filter paper, and when the latter has become colored add a drop of satd. HgCl_2 soln. In presence of stercobilin a brick-red color develops. If the stain is too light to transfer to paper, tease apart a small fragment of the cloth, divide into 2 portions, place side by side on a slide, moisten one portion with H_2O and the other with satd. HgCl_2 , and compare. The reaction may take a few min to develop. A. PAPINEAU-COUTURE

Diagnosis of asphyxiation by submersion by means of crystalline micro-particles from the water. E. STOCKIS. *Ann. méd. légale* 1, 43-8(1921).—The method is based on the passing of some of the asphyxiating water through the walls of the lung cells and capillaries and into the blood stream, together with the solid particles which it contains. The latter can be found in both sides of the heart. The constituent most generally selected for identification is SiO_2 ; but its detection is complicated by the presence of traces of SiO_2 in most of the usual reagents (including distd. H_2O) unless specially purified, and also of small quantities in normal blood and urine. Detn. of SiO_2 in the whole heart has given interesting results, but is delicate and tedious and prevents the use of the organ for other investigations. Preliminary autolysis of the heart at 37° requires more time, but facilitates subsequent incineration. Hearts of drowned corpses contained 10-20 mg. SiO_2 , while in other kinds of death it contained not over 5-6 mg. S. recommends withdrawing the liquid first from the left, then from the right side of the heart into a perfectly clean vessel (treated with H_2SO_4 and rinsed with filtered distd. H_2O), centrifuging, and examg. the deposit under a polarizing microscope on perfectly clean microscope slides kept in NH_3 aq. SiO_2 can also be detd. quant. in the centrifugal deposit. A blank should be run on the reagents used, and also, when possible, of the water in which the drowning occurred. A. P.-C.

Toxicological investigations on acute alcoholism in man. BALTHAZARD AND MARCELLE LAMBERT. *Ann. méd. légale* 1, 83-96(1921).—A detailed study of the Nicloux method (see Derome and Pepin, *C. A.* 19, 1391) from a toxicological and forensic standpoint. With pure alc. solns. the method is accurate to 1-2%, but in the analysis of blood, etc., the accuracy is about 5%, which is amply sufficient in forensic work. The amt. of alc. which can be normally present in blood during digestion is of the order

of 0.01 cc. per l., never over 0.04 cc., and quite negligible for legal work. Presence of AcOH, AcH and traces of fatty acids in the distillate does not affect the accuracy of the results. When the analysis is carried out before putrefaction has set in, the only oxidizable volatile substances which could introduce an error in the EtOH detn. are Et₂O and CHCl₃; and it is generally easily ascertained if the victim had taken any a short time before death. If putrefaction has set in, volatile oxidizable compds. are formed, which can be eliminated by distg. first from acid and then from alk. soln. In man, EtOH diffuses in all the humors and all the organs till its distribution is practically uniform, so that analysis of the blood is sufficient. The max. alc. content of the blood (in cc. per l.) represents exactly the quantity of alc. ingested (in g. per kg. of body wt.) within the preceding 2-3 hrs. Elimination from the blood is complete in 7-15 hrs. Presence of 3 g. per l., or over, of EtOH in the blood always corresponds to a condition of inebriety or drunkenness, even in confirmed alcoholics; while contents of 2-3 g. per l. can correspond to nervous troubles in subjects unaccustomed to alc. beverages.

A. PAPINEAU-COUTURE

The toxicological determination of alcohol. FLORENCE. *Ann. méd. légale* 2, 10-7(1922).—Critical discussion of the Nicloux method for detn. of EtOH in blood, urine, etc. F. considers that detn. is not sufficient but that EtOH should be identified qual., and outlines the various tests that can be applied, including the following: distil the suspected alc. liquid to half vol. from acid soln., redistil the distillate to half vol. from alk. soln., to 1-2 cc. add KMnO₄ soln. and a drop of H₂SO₄, warm very slightly, if decolorized add more KMnO₄ and repeat till the color remains permanently, neutralize with NaOH and add Nessler's reagent. An abundant (quant.) red ppt. indicates presence of EtOH. The Nicloux method is unreliable because of irregularities in the oxidation of EtOH. F. suggests adding an excess of K₂Cr₂O₇ and titrating the excess iodometrically; but even here there is some loss of AcH before the oxidation to AcOH is complete. Heating under a reflux condenser causes partial oxidation of the AcOH. With a doubly distd. liquid, the EtOH can be detd. from the surface tension by means of a Duclaux pipet, the accuracy of which is higher than 0.5 drop, corresponding to about 0.1% EtOH, when working with 5 cc. at 15°. The final result should be corrected for a loss of about 1% of the EtOH at each distn. NICLOUX. *Ibid* 18-9.—Reply to Florence's criticisms of his method. A. P.-C.

Examination of urine stains. V. BALTHAZARD AND N. ROJAS. *Ann. méd. légale* 2, 33-7(1922).—Richaud's reagent (Na phosphotungstate 25, concd. HCl 5, H₂O 250) is modified to Na phosphotungstate 1 g., H₂O 50 cc. Add a drop of reagent to the stain, and then a drop of NaOH soln. Urine gives a Prussian blue coloration, as strong as that obtained with the original reagent. A positive test is obtained after a 50:1 diln. of the urine, or with stains of known origin which had been previously washed. Pure saliva, blood serum, milk, gastric juice and fecal matters also give the reaction but with much slighter intensity, and not at all after diln. Blood, sperm, egg albumin and unstained fabrics do not give the reaction. The reaction is characteristic of uric acid and its derivs. alloxan and alloxantin. Prep. a concd. stock soln. of xanthrydrol in 95% EtOH, immediately before use mix a few drops with an equal vol. of AcOH, add 1-2 drops of reagent to the soln. of the stain or directly to a stained fiber on a microscope slide, cover with a coverglass, and seal the edges with paraffin to prevent evapn. In presence of urine characteristic xanthylurea crystals are formed, generally within 30 min., sometimes only after several hrs.; they are readily detected under low magnification. The reaction is characteristic of urea, and can be obtained to a slight extent with pure blood serum. Application of both tests with positive results is specific of urine stains, especially when the material was dild. before testing. A. P.-C.

Detection of wine in stomach contents. (MRS.) BALTHAZARD. *Ann. méd. légale* 2, 240-2(1922).—The most characteristic constituents are tartaric acid and coloring matter (for red wines only). The former can be detected by Denigès' reaction (2% resorcin with an equal vol. of H₂SO₄), by Pinerula's reaction (β-naphthol in H₂SO₄) or by identification of the crystals with a polarizing microscope. The coloring matter is identified by the green color it gives with NH₃, restored to wine-red by HCl or tartaric acid. The test can be applied to filter paper stained with the stomach contents and then dried. In doubtful cases, add a slight excess of NH₄OH to the stomach contents, sep. from the solid matter, add 50% alc., filter, ppt. the color with Hugoueney's aceto-tartaric reagent (*Bull. soc. chim.* 1891, 89), evap. off the alc., take up the color in dil. NH₄OH, and add HCl. The change from green to red, and inversely, can be obtained repeatedly. The reaction is given by red grape skins, violet plum skins, gooseberries, raspberries and blackberries. A. PAPINEAU-COUTURE

Determination of methemoglobin in blood. P. DUCOU. *Thesis*, Paris (1925); *Ann. méd. légale* 6, 84(1926).—Study of methemoglobin (I) showed that: (1) oxyhemoglobin (II) is converted into I *in vitro*, not only under the action of a large variety of chem. reagents, but also spontaneously when the blood is protected from putrefaction; (2) it is the latter condition that allows of its exptl. production in Nicloux's method, consisting in adding 10% of 90% alc. to the blood; (3) I contains 50% less O than II; (4) I is less stable than II; (5) I has an absorption band in the red portion of the spectrum, located at $\lambda = 633$ in acid medium, $\lambda = 601$ in alk. medium and $\lambda = 607$ in NaF soln.; (6) I does not form a compd. with CO; I can be detd. quant. either by Nicloux and Fontès' chem. method or by Balthazard and Philippe's phys. method; (8) acetanilide is a very active methemoglobinizing agent *in vivo*; (9) treatment for methemoglobinemia consists essentially in O inhalations.

Carbon monoxide in wounds from firearms. STOCKIS. *Rev. droit pénal intern. arch. méd. légale intern.* (Feb., 1922); *Ann. méd. légale* 2, 190(1922).—In most wounds from revolvers or automatic pistols, if the shot was fired from a distance of less than 20 cm., CO produced by deflagration of the powder or of the detonator can be detected in the blood in the immediate neighborhood of the wound, whether or not the skin was protected by clothes in this particular spot.

A. PAPINEAU-COUTURE

Microdetermination of lactic acid in blood. J. FREJKA AND K. VŠETEČKA. *Spisy Přírodovědeckou Fakullou Masarykovy Univ.* 1925, No. 60, 3-25.—A detailed investigation into the chief methods of detn. of lactic acid in physiol. fluids (urine, blood, muscle ext., etc.) with a view to devising a method for its microdetn. in blood. Detns. were carried out by the various methods before and after addn. of known amts. of lactic acid. The gravimetric method gave 83-84% of the amt. added to blood, and 88-90% in broth. The lactate sepd. contained about 14% impurities, reducing the actual lactic acid recovered to about 80%. In presence of β -hydroxybutyric acid the results are unreliable; comparison with the Mondschein method (C. A. 6, 2630, 2631) showed differences of 30-60%. Yoshikawa's polarimetric method (C. A. 8, 940) gave 99-100% in urine and 91-94% in liver ext.; but it is unsuitable for physiol. liquids which contain other optically active substances. Meissner's method (C. A. 9, 1188) gave 93-96% for broth, 95-100% for blood, 98-104% for urine and 80-92% for pure lactic acid. In presence of HCO_2H the results rose to 108-124%. The broth was prepd. by boiling without alkali to avoid, as far as possible, decompn. of sugars and other compds. to lactic acid. The high results obtained with urine are attributed to the presence of HCO_2H or other acids which can cause formation of lactic acid. Polonovsky's colorimetric method (C. A. 14, 3434) gave 90-97% and is recommended as a rapid routine method for the classification of samples. With pure lactic acid the Fürth-Charnass method (*Biochem. Z.* 26, 240) gave 86-92% with the theoretical factor 0.0045, and 96-102% with the empirical factor 0.0050. The modification using 0.02 N KMnO_4 (C. A. 5, 51) gave 95-98%, and the Schmidt-Oppenheimer modification 97-100%. The same method applied to broth extd. with Et_2O gave 95-96%, and to broth extd. with AmOH 89-95%. Detn. of lactic acid in presence of β -hydroxybutyric acid by the Mondschein method (C. A. 6, 2630, 2631) gave 93-96%. Detn. in urine *via* Dapper gave 87-88% and *via* Ishihara (C. A. 7, 2588) 93-96%. It was found that the ext. contg. the lactic acid was consistently contaminated by a small quantity of Et_2O , by aldehydes, ketones and other decompn. products of Et_2O , which can combine with SO_2 or with I if the Et_2O is removed by distn. Bellet's method (C. A. 7, 2531) gave 97.3-98.9% with blood and 98.4% with broth; with urine it gave 96.9-98% by the following modification: ppt. the urine with phosphotungstic acid, eliminate the excess of the latter with Ba(OH)_2 , and the excess of the latter in turn with Na_2SO_4 , acidify the concd. filtrate with H_3PO_4 , add anhyd. Na_2SO_4 , ext. with Et_2O and then proceed *via* Bellet. For microdetn. of lactic acid in blood, dil. 10 cc. with 10 cc. H_2O , ppt. with 8 cc. of freshly prepd. $\text{Hg(NO}_3)_2$, after 5 min. filter and wash, ppt. the excess of $\text{Hg(NO}_3)_2$ with KOH , neutralize the filtrate with HCl , filter, evap. on the water bath, add 1.5 cc. H_3PO_4 , sat. with anhyd. Na_2SO_4 , triturate with sand, ext. for 2 hrs. with a weighed amt. of boiling Et_2O , evap. a weighed aliquot of the ext. in presence of a little NH_3 , dil. with 50 cc. H_2O , evap. about 30 cc., acidify the residue with H_2SO_4 , and then oxidize *via* Bellet with 0.01 N KMnO_4 . The min. quantity of blood which should be taken is 5 cc. With 1 mg. lactic acid, the method gave a recovery of 97.3-102% on the pure acid, and 96-101% recovery in blood, which is sufficiently accurate for clinical work.

A. PAPINEAU-COUTURE

The estimation of small quantities of bismuth in the urine. C. A. HILL. *Lancet* 1925, II, 1281.—Org. matter is destroyed by low heat with HNO_3 . To the aq. soln. contg. HNO_3 , add 0.3 g. urea and 0.5 g. phenazone and, while shaking, add about 0.05 g.

KI crystals one at a time until the max. color develops. Compare with a standard contg. 0.62 g. BiCO_3 in 10 cc. HNO_3 (sp. gr. 1.4) made to 1 l. and then dil. 10 cc. of the to 1 l. For comparison take 10 cc. of this standard soln., contg. 0.05 mg. Bi, + 1 drop HNO_3 , made to 50 cc. and add reagents as specified above. F. B. SEIBERT

New method for the determination of the molecular weight of the proteins. TH. SVEDBERG AND ROBIN FAHRÆUS. *J. Am. Chem. Soc.* **48**, 430-8(1926).—A method is described for the detn. of the mol. wt. of proteins based upon the measurement of sedimentation equil. in a protein soln. exposed to a centrifugal force. Preliminary measurements are reported for CO-hemoglobin and methemoglobin, which indicate that hemoglobin solns. are built up of mols. contg. 4 groups of mol. wt. 16,700; that is, the mol. wt. of hemoglobin in aq. soln. is probably 68,000. C. J. WEST

Identification of creatine. R. J. WILLIAMS AND P. A. LASELLE. *J. Am. Chem. Soc.* **48**, 536-7(1926).—Creatine decomps. with marked effervescence at about 291 (cor.); it forms thin, tabular, monoclinic prisms, which, when observed perpendicular to the 100 face, appear orthorhombic; observed perpendicular to the clino-pinacoid (010) they show a max. extinction angle of 45° . Four out of 5 persons pronounced it tasteless, but a dry burning sensation was produced in the back of the mouth which was not noticeable for a min. or two but persisted for some time afterwards; the fifth described it as bitter. C. J. WEST

Measurements with the quinhydrone electrode (LINDERSTRØM-LANG) 7.

C—BACTERIOLOGY

A. K. BALLS

Pigment formation by fungi. A. N. DANILOV. *Ber. deut. botan. Ges.* **43**, 27-33(1925).—The fungus *Isaria virescens*, Elenk. et Danil., growing on suitable media is able to produce a range of pigments. The formation of these pigments depends on light, temp. and the nature of the medium. For instance, a culture in the dark may be colorless, but on exposure to light rose, orange and red tints develop; increase in temp. favors the formation of dark brown colors. Mg stimulates, while Li suppresses pigment formation; Na is practically without effect. B. C. A.

The effect of the electric current on microorganisms. Electrical food conservation. MAX. KLEIBER. *Biochem. Z.* **160**, 312-24(1925).—An a. c. of 3-4 v. and 7-8 milliamps. did not diminish fermentation in beer wort or must. D. c. of the same strength and voltage, however, diminished yeast fermentation. The thermal death point of yeast was not altered by the elec. current. The action of the current is on the medium rather than on the cells themselves. These results apply to problems of *elec. silage*.

F. A. CAJORI

Lactic acid fermentation. II. A. I. VIRTANEN, H. KARSTRÖM AND R. BÄCK. *Z. physiol. Chem.* **151**, 232-41(1926); cf. *C. A.* **19**, 1878.—Glyceraldehyde, dihydroxyacetone, methylglyoxal and pyruvic acid are not utilized as sources of C nor fermented by the typical lactic acid bacteria, *Str. lactis* and *B. casei* etc. Dry preps. of the bacteria produce no lactic acid from these 3 C compds. On the other hand, the 3 trioses lose their power of reducing Fehling soln., much more rapidly in the presence of the dry prepn. Lactic acid bacteria contain no carboxylase. The presence of CaSO_4 does not influence lactic acid fermentation. A. W. DOX

Some results of the study of the metabolism of bacteria. H. BRAUN. *Krankheitsforschung* **1**, 251-6(1925).—If bacteria are grown upon meat exts. one does not usually recognize the intermediate products. Cultures grown on plain artificial media are hardier but not less virulent; they may lack several less essential chem. substances of the ectoplasm. Some species, as the human tubercle bacillus, may live upon air, ob-

taining N and C from impurities in air. While some bacteria can assimilate N from ammonia, others of the same culture, even sister cells, may lack this power. In synthetic media, if ammonia is the source of N and org. acids of C, much O_2 must be present. Study of the metabolism of bacteria offers a solution to many problems of the physiology of fermentation.

P. Y. JACKSON

The variation in the amount of soluble protein contained in old broth cultures of *B. typhosus*. J. W. CORNWALL. *Indian J. Med. Research* 13, 483-90(1926).—"The amt. of sol. protein in broth cultures of *B. typhosus* rises continuously to a max. which is reached after 7 to 12 weeks of incubation and then falls. This protein is derived from a soln. of parts of the bodies of dead bacilli. . . . The rise in the sol. protein curve indicates that a larger amt. of protein derived from the soln. of bacterial bodies is being added to the fluid than is being abstracted by degradation of protein." The fall in the sol. protein curve indicates the reverse.

FRANCES KRASNOW

Observations on Castellani's phenomenon. J. M. FIALLOS. *J. Trop. Med.* 28, 426-8(1925).—F. confirms Castellani's observation: That "2 bacilli, neither of which causes production of gas in certain C compounds, may do so when artificially mixed together, provided one of them is capable of producing simple acidity (never gas) in those C compds. and the other though inert on these compds. (*viz.*, does not produce either acid or gas) is capable of producing gas in glucose."

FRANCES KRASNOW

The behavior of pyrimidine derivatives in organisms. II. The action of *B. coli* on uracil and cytosine. AMANDUS HAHN AND L. SCHÄFER. *Z. Biol.* 83, 511-4(1925).—By means of *B. coli* activity, cytosine is deaminized to uracil; uracil is not acted upon. This behavior is analogous to that of yeast which likewise changes cytosine to uracil and does not attack uracil.

FRANCES KRASNOW

The antiseptic action of copper chloride in solvents of different dielectric constants. N. KLISSIUNIS. *Biochem. Z.* 159, 107-9(1925); cf. *C. A.* 19, 2354.—The antiseptic action of $CuCl_2$ in iso-AmOH, PrOH, iso-PrOH, EtOH, MeOH, $(CH_3)_2CO$, glycol, glycerol and H_2O is studied. Antiseptic action is shown only in EtOH, MeOH, glycol and H_2O .

W. D. L.

Acid agglutination of *Bacillus coli*. FR. SARTORIUS. *Z. Immunitäts.* 45, 478-92 (1926).—Freshly isolated strains of *B. coli* increase steadily in agglutinability. The optimal reaction for agglutination lies between 0.01 and 0.002 N HCl. Other mineral acids act similarly to HCl. Small concns. of salt in general increase agglutination in the presence of acid, while large concns. inhibit it.

E. R. LONG

The formation of fat by yeast. IDA S. MACLEAN AND D. HOFFERT. *Food Investigation Board, report for the year 1924. Dept. Sci. Ind. Research* 1925, 66-8; cf. *C. A.* 18, 998; 19, 1288.

D—BOTANY

B. M. DUGGAR

The salt requirements of *Lupinus albus*. C. H. ARNDT. *Soil Science* 21, 1-6 (1926).—*Lupinus albus* was grown in sand and soln. cultures using standard methods, and the results were analyzed graphically by the triangle method. A total salt concn. of 0.0084 N with respect to cations was most favorable for growth. The ratios of 5:3:4 for K, Ca and Mg and 5:9:4 for NO_3 , PO_4 and SO_4 ions, resp., gave the best returns. A soln. composed of 0.0035 N KNO_3 , 0.6021 N $CaH_4(PO_4)_2$ and 0.0028 N $MgSO_4$ produced good growth even when the p_H value was less than 3.6. High concns. of PO_4 tended to produce chlorosis. No evidence was found which justified the application of the term "calciphobe" to the plant.

R. BRADFIELD

A brief note on the biochemical reactions of certain fungi, *viz.*, *Monilia krusei*, *M. macedoniensis* and *M. tropicalis*. E. C. SPAAR. *J. Trop. Med.* 29, 47-8(1926).—The investigation shows that the reactions are const. and agree with the findings of Castellani.

FRANCES KRASNOW

Extra feeding of carbon dioxide to plants. ANTONIN ROLET. *Rev. gen. sci.* 36, 541-6(1925).—A general review.

H. R. KRAYBILL

"Forcing" plants by means of hydrogen cyanide. G. GASSNER. *Ber. deut. bot. Ges.* 43, 132-7(1925).—Exposure to low concn. of HCN stimulates growth in a number of trees and shrubs. Species that are normally dormant during the winter may be forced into growth by regular treatment with the gas. The optimum concn. varies

for different species but in general an exposure of 1 hr. daily to an atm. contg. the equm of 11.3 g. liquid HCN per cu. m. gives satisfactory results. W. NEWTON

Supposed poisonous action of carbon monoxide on green plants. C. WEHMLER. *Ber. deut. bot. Ges.* 43, 184-8 (1925).—Seedlings of cress and barley are not injured when grown for 10 days in atms. contg. up to 50% CO. In contrast, seedlings wilt within 3 days in the presence of small amts. of H₂S, C₆H₆, CS₂, HCN and other poisonous gases. W. NEWTON

The seeds of Mercurialis species. P. GILLOT. *J. pharm. chim.* [8], 2, 129-31 (1925); cf. *C. A.* 20, 479.—Chem. analysis of the seeds of *Mercurialis annua*, *M. perennis* and *M. tomentosa* gave, resp.: H₂O 6.8, 9.58, 6.72%; fat 38.05, 26.45, 35.62%; protein 13.55, 19.43, 15.25%; cellulose 31.91, 39.55, 33.13%; reducing sugar 0.09, 0.30, 0.07%; hydrolyzable sugar 1.29, 1.49, 0.97%; starch 0.39, 0.10, —; ash 7.92, 4.10, 8.24%. The characters of the oil, obtained by cold pressure or extr. with petroleum ether, closely resemble those of linseed oil: d_{15}^4 0.934-0.937, n_D^{15} 1.4840-1.4861, I no. (Wijs) 201.5-215.5; Br no. (Hehner and Mitchell) 52-80. The possible uses of this oil as a siccative, notably in *art painting*, are pointed out. S. WALDBOTT

Effect of the concentration of K salts in soil media upon the carbohydrate metabolism of plants (ENGLIS, LUNT) 15.

I:—NUTRITION

PHILIP B. HAWK

Crystals of vitamin B from the mung bean. H. H. M. BOWMAN AND M. A. YEE. *Proc. Soc. Exptl. Biol. Med.* 22, 228-31 (1925).—Dry ground meal was thrice extd. in a reflux condenser with 80% CH₃OH and 2% HCl. The filtrates were freed from CH₃OH by evapn. at low pressures; fats and org. acids were removed by ether; the soln. was then acidified with H₂SO₄ and a ppt. obtained with phosphotungstic acid. The ppt. was then extd. with acetone and Ba(OH)₂, and the filtrate successively treated with H₂SO₄, Pb acetate and H₂S. The soln. was then evapd. and needle-shaped crystals were obtained; these were recrystd. from 80% C₂H₅OH. The pure crystals m. 320° were not identified as uric acid, amino acids or protein. They gave a yellow ppt with aq. Br and a blue color with Folin-McCallum reagent. Doses of 3 mg. intramuscularly cured pigeons of polyneuritis. C. V. B.

The experimental production of lack of carbohydrates, and the carbohydrate metabolism of the central nervous system. L. ASHER AND K. TAKAHASHI. *Proc. Soc. Exptl. Biol. Med.* 22, 238-40 (1925).—The method applied to rats consisted of feeding Witte peptone for a few days, followed by thyroid gland preps., the injection of phlorhizin by the Coolen method, and finally work on a treadmill. The carbohydrate of the liver was lowered 96%, of the muscle 85%, and the blood sugar to the low level of insulin hypoglycemia. The above method depleted the glycogen of the brain 20%. Convulsions in the rabbit following the injection of picrotoxin caused an 80% reduction in brain glycogen. C. V. B.

What is the saturation point? C. B. MORISON AND R. H. SHAW. *Baking Tech.* 5, 49-53 (1926).—The purpose of the investigation was to note the effects of a selected diet contg. various amts. of bread made from a known formula on the growth of lab. animals. Exptl. diets were prepd. from mixts. of the basic diet and dried ground milk bread contg. (1) 75% of the total calories as basic diet and 25% as the dried milk bread, (2) 50% of the basic diet and 50% as dried milk bread, (3) 25% of the calories as basic diet and 75% as milk bread. Graphs shown indicate good growth for diets 1 and 2 but not so good on 3. Results reported are based on a relatively short period of observation and are being continued to include a longer time. RUTH BUCHANAN

Mineral elements in nutrition with special reference to calcium and phosphorus. H. C. SHERMAN, et al. *Am. J. Pub. Health* 14, 513-7 (1925); *Expt. Sta. Record* 53, 161; cf. *C. A.* 19, 2691.—This rept. of the comm. on nutritional problems of the American Public Health Assoc. deals with the requirements of the human body for Ca and P and the importance of these elements as factors in nutrition and health. H. G.

The variations in the excitability of the vagus and vaso-motor apparatus, and the physiology of inanition. P. ALBERTONI. *Arch. sci. biol.* (Italy) 6, 439-61 (1924); *Physiol. Abstracts* 10, 175.—The blood of thyroparathyroidectomized dogs contains

toxic substances capable of lowering the av. blood pressure of normal ones. In the operated animals this is not observed because of a hyperactivity of the adrenals and pituitary body. Iodothyron (thyron) and endothyronin increase the pulse rate. The blood of hypermegalic subjects has sometimes a lowering effect on blood pressure. The active principles of the thyroid increase the excitability of the inhibitory center of the heart, but do not modify the action of adrenaline on the tonus of blood vessels. Inanition has *per se* no influence on blood pressure, but the increase due to adrenaline is smaller in fasting than in normal dogs. The increase caused by injections of glucose is the same in both sets of animals. In inanition the vaso-motor reactions due to asphyxia are weaker and the excitability of the vagus is greater than normally. In protracted inanition, however, the excitability of the vagus diminishes and finally disappears. The bilateral section of the vagus in fasting dogs is followed by an increase in the blood pressure somewhat greater than normal. The action of atropine on the vagus is not influenced by inanition, while that of pilocarpine may completely fail in advanced inanition. The vaso-motor response to elec. stimuli of the sympathetic is weaker in fasting than in normal animals. When the vagus or the sympathetic is stimulated, a modification in the distribution of the electrolytes in the cell membranes appears to occur.

H. G.

Effect of ultra-violet light on protein metabolism. S. YOSHIE. *Strahlentherapie* 18, 201-11(1924); *Ber. ges. Physiol. exper. Pharmacol.* 29, 579.—One hr.'s irradiation during 8 consecutive days caused in dogs a slight increase of the positive N balance with a slight decrease of amino acids in the urine. A further daily irradiation of 2 hrs. produced no change, a daily 4-hr. irradiation a negative N balance. Prolonged irradiation was followed by inhibited absorption of N compds. by the intestine and disturbance of health.

MARY JACOBSEN

The relation of calcium and phosphorus in the diet to the absorption of these elements from the intestine. W. J. ORR, L. E. HOLT, JR., L. WILKINS AND F. H. BOONE. *Am. J. Diseases Children* 28, 574(1925); cf. *C. A.* 18, 105.—Excessive amts. of Ca in the diet tend to increase the total absorption and retention of Ca, but tend to impair P retention. Excessive amts. of P in the diet exercise an unfavorable influence on the Ca metabolism, and are accompanied by an increase in the Ca lost in the feces. Formation of $\text{Ca}_3(\text{PO}_4)_2$ explains this behavior.

I. NEWTON KUGELMASS

Light and vitamin A. C. E. BLOCH. *Am. J. Diseases Children* 31, 315-22(1926).—Exposure to either C arc light or to sunlight does not cure xerophthalmia. Light cannot replace vitamin A nor supply it to the animal organism. Ultra-violet radiations are absorbed either by direct exposure or through articles of diet (cod-liver oil, yolk of eggs, milk, etc.).

I. N. K.

The effect of fermentation with specific microorganisms on the vitamin C content of orange and tomato juice. S. LEFKOVSKY, E. B. HART, E. G. HASTINGS AND W. C. FRAZIER. *J. Biol. Chem.* 66, 49-56(1925).—Attempts to det. the cause for the disappearance of vitamin C from fermented corn (silage) and fermented cabbage (sauerkraut) have been made. The actions of several organisms occurring in silage have been studied but it has not been shown that they destroy vitamin C. The destructive action of O_2 was eliminated in the expts. by excluding air from the fermenting mixts. by the use of vaseline plugs from $\frac{1}{2}$ to $\frac{3}{4}$ in. in thickness covering the inoculated juice. It is very probable that the destruction of vitamin C in fermenting plant tissues is to be referred to the O_2 still retained in the mass.

A. P. LOTHROP

Potassium in animal nutrition. III. Influence of potassium on total excretion of sodium, chlorine, calcium and phosphorus. H. G. MILLER. *J. Biol. Chem.* 67, 71-7(1926); cf. *C. A.* 17, 1272.—"The effect of high K on the total excretion of Na, Cl, Ca and P in mature rats receiving a ration of casein, dextrin, agar, yeast and milk has been studied over periods of 2 weeks duration. The introduction of K salts into the diet caused an immediate increase in total Na and Cl excreted, after which the amts. of these elements excreted were only slightly greater than on the basal ration. During certain periods of high K feeding the total Ca and P excreted increased a small amt. compared to a like period on the basal ration; however, the av. daily excretion of Ca and P was slightly increased over the low-K period. Considering the abnormally high level (0.1-0.2 g. daily) at which K was fed in this expt. and results obtained in previous expts., there is no reason to believe that K occurring in natural foodstuffs will cause an increased excretion of other elements when they are needed for normal physiol. development."

A. P. LOTHROP

Diabetic diets in grams per kilogram of body weight. H. GRAY. *J. Am. Med. Assoc.* 84, 14(1925).—In 140 diabetic children receiving an av. of 20 units of insulin per day the g. per kg. of body wt. were 2.6 for carbohydrate, 2.1 for protein and 4.1

for fat per 24 hrs. The total calories were 55 per kg. of body wt. A tabulation of the diets recommended by other authorities is given which is based on 120 cases. The av. of G.'s cases shows less protein intake and fewer calories than in the other clinics reviewed.

F—PHYSIOLOGY

ANDREW HUNTER

Liberation of phosphoric acid after fatiguing work of frog muscles. GUSTAV EMBDEN AND HERBERT HENTSCHEL. *Z. physiol. Chem.* 151, 167-202(1926).—Each stimulation of the isolated frog muscle (gastrocnemius and semimembranosus) brings about a residual increase in PO_4 after termination of the work period. The cleavage of PO_4 was not observed regularly after 275 individual stimuli at a definite frequency, but was noted invariably after 550 stimuli, and in general it gradually increased with increasing no. of stimuli. Under otherwise uniform conditions the liberation of PO_4 is greater in the more heavily loaded muscle. In long-continued tetanic stimulation, as well as in a sufficiently prolonged period of individual stimuli, the cleavage of PO_4 is regularly observed. With the semimembranosus, but not with the gastrocnemius, a brief tetanic stimulation, on the contrary, led to a distinct decrease in PO_4 . This is referred to a synthesis-promoting action of the lactic acid formed in tetanus. If the stimulation has not been too greatly prolonged, the liberated PO_4 is partially re-synthesized to lactacidogen or a similar substance during subsequent recovery in O. The synthesis can also take place when the stimulated muscle is placed in H, but the result is less uniform than with O. By the subsequent re-synthesis of the liberated PO_4 the results of expts. are brought into correlation where under otherwise uniform conditions a slower stimulation led to a smaller PO_4 cleavage than a more rapid stimulation. With uniform tempo of stimulus, muscles which were directly comparable showed immediately after the stimulation a greater liberation of PO_4 in air and in H than in O.

A. W. Dox

The influence of temperature on the formation of phosphoric acid during fatiguing muscular work. MANFRED ALTMANN. *Z. physiol. Chem.* 151, 203-8(1926).—Long-continued uniform stimulation of the 2 gastrocnemii of the frog showed that the PO_4 cleavage at the end of the stimulation period is largely dependent on the temp. At 25° a much greater increase in PO_4 occurs than at 5°.

A. W. Dox

The course of lactic acid formation in tetanus. G. EMBDEN, H. HIRSCH-KAUFFMANN, E. LEHNARTZ AND H. J. DEUTICKE. *Z. physiol. Chem.* 151, 209-31(1926).—With brief tetanic stimulation of isolated frog muscle, the lactic acid formation does not cease directly after termination of the stimulation and relaxation of the muscle, but continues during the next 5-30 seconds. The increase is often extraordinary, the rate frequently exceeding that of rest anaerobiosis by several hundred times. The lactic acid increase is, therefore, not dependent on the state of contraction, but can progress much further after cessation of the contraction. If these relations hold also for shorter tetani, as appears probable, the total lactic acid formation during a more extended period of work should no longer be referred to the actual time of contraction. If, therefore, a very considerable portion of the lactic acid is not formed until after the contraction, the energy liberated by exothermic lactic acid formation from carbohydrate, in addn. to the related exothermic processes (heat of neutralization with alkalis and proteins), is not sufficient as a sole source of energy, and it becomes necessary to seek other sources for the energy output during the moment of contraction. These sources might exist either in unknown exothermic chem. reactions or might be of a physicochem. (non-chem.) nature. The demonstration of colloid changes proceeding with positive heat tone during the contraction would be of the greatest significance. In fatiguing muscular activity, changes occur in the biol. behavior of the musculature and these are probably referable to a colloid change in the intrafibrillary proteins. It is conceivable that in the moment of contraction colloid changes occur and the energy discharged is of a physicochem. nature. Perhaps the exothermic chem. reactions, whether oxidative or fermentative, then serve to re-charge a sort of physicochem. accumulator which discharges in the moment of contraction. Rigor mortis may be regarded as a process similar to contraction, since it may be accompanied by a decrease in lactic acid without increase in PO_4 .

A. W. Dox

The effect of environmental temperature on metabolism. S. MORGULIS. *Am. J. Physiol.* 71, 49-59(1924); *Physiol. Abstracts* 10, 233.—The metabolism of dogs was

recorded by means of a Benedict closed circuit app. If the animal remains quiet, there is no change in the metabolic rate with rise of temp.; increase in heat rate and muscular tone may raise the metabolism, apart from actual movements (restlessness, shivering). This increase is produced reflexly; there is no special mechanism of chem. regulation of metabolism. An animal with its hair clipped is more sensitive to cold, and its metabolism is at a min. at a higher temp. Hence in metabolic studies the heat-regulating mechanism of the subject must be in equil.; this introduces an additional factor which must be controlled.

Metabolism of cattle during standing and lying. J. A. FRIES AND M. KRISS. *Am. J. Physiol.* 71, 60-83(1924); *Physiol. Abstracts* 10, 233.—In previous expts. no account was taken of the storage of heat by the platform on which the animal lay, with its subsequent radiation out when the animal assumed the standing posture. The amt. of this heat can be calcd. if it is assumed that the ratio of the CO₂ to the heat production is the same during the 2 periods. The true increase in heat production on standing as compared with lying is about 26 cal. an hr. for a cow of 400 kg.; the increase is proportional to the $\frac{2}{3}$ power of the weight of the animal. The day's heat production can thus be adjusted to a standard day of 12 hrs. standing and 12 hrs. lying. H. G.

The transformation of energy in the muscles. VII. **Origin of heat during muscular contraction.** O. MEYERHOF. *Arch. ges. Physiol.* (Pflüger's) 204, 295-331(1924); *Physiol. Abstracts* 10, 214; cf. C. A. 19, 3299.—The true heat value of water-free glycogen is 3815 cal., that of C₆H₁₀O₆·H₂O being 3799 cal., and that of glycogen in soln. 3790 cal.—i. e., 188 cal. more than the corresponding quantity of lactic acid. Fermentative hydrolysis of 1 g. glycogen hydrate to maltose + glucose liberates 10 cal. The heat of neutralization of lactic acid in muscle is about 185 cal. per g. At least 70 cal., perhaps as much as 120 cal., of the heat of contraction of muscle have yet to be accounted for. H. G.

Action of pituitary extracts on the respiratory center. U. G. BIJLSMA. *Arch. néerland. physiol.* 9, 422-3(1924); *Physiol. Abstracts* 10, 220.—Small doses stimulate, large doses inhibit, respiration in the decerebrate cat; the effect occurs after the use in blood pressure. H. G.

Creatinine tests for renal function. R. H. MAJOR. *Missouri State Med. Assoc. J.* 22, 54(1925); *Physiol. Abstracts* 10, 227.—The creatinine test consists in the estn. of the creatinine excretion before and after the introduction of creatinine into the circulation. In normal subjects the kidneys, in the hr. following the injection, excrete from 2 or 3 times as much creatinine as was excreted before injection. During the second hr. after injection 50-100% more is excreted than during the preinjection hr. In chronic nephritis the creatinine excretion the hr. after injection showed, as a rule, only a slight rise over that of the preinjection period. In some cases of severe nephritis the curve of creatinine excretion showed a fall. This type of curve is apparently of some prognostic import. It has also been found in exptl. U nephritis when the creatinine test is carried out every day; it appears in animals during the second and third day after administration of U, at the time when the nephritis reaches its max. intensity. H. G.

Contribution to the physiology of the stomach. Influence of experimental changes in blood sugar level on gastric hunger contractions. I. BALATAO AND A. J. CARLSON. *Pavlov's Jubilee Vol.* 1925, 125-32; *Physiol. Abstracts* 10, 160.—Hyperglucemia produced by intravenous injection of glucose inhibits gastric hunger contractions. Insulin hypoglucemia increases gastric tonus and the hunger contractions when the blood sugar concn. falls to 0.08 to 0.07%. As the blood sugar falls towards convulsion level the stomach shows alternate periods of atony and tetany. Glucose inhibits the gastric tetany of hypoglucemia. In diabetic dogs insulin produces a depression of gastric tonus and contractions, followed by increased tonus and contractions when the initial stage of hypoglucemia is reached. Intravenous injection of glucose does not inhibit gastric tonus and contractions in diabetic dogs except when hypoglucemia and gastric tetany are induced with insulin. It is suggested that gastric tonus and contractions increase with the reduction of the tissue glycogen. None of these effects can be produced by injections of lactose or NaCl. H. G.

The importance of the harderian gland in cholesterol metabolism. I. MOISSEJEFF. *Z. ges. exptl. Med.* 47, 359-68(1925).—In contrast to the adrenal, the harderian gland of the rabbit shows no accumulation of cholesterol or cholesterol esters, even with an increase in the cholesterol content of the organism. This gland is to be considered as a true excretory organ for cholesterol and presumably for other lipids and not as a storage place for cholesterol like the adrenal. HARRIET F. HOLMES

Studies of salivary amylase in infants in the first months of life. CESARE COCCHI.

Riv. clin. pediatr. **22**, 449-76(1924); *Ber. ges. Physiol. explil. Pharmacol.* **29**, 463.—An exhaustive critical review of the former studies and a detailed investigation of a large material. Salivary secretion was stimulated by a saccharine soln. After 2 hrs' incubation with sterile starch maltose was detd. by the method of Fehling-Arthus. Infantile saliva is always alk. The amylolytic power is already pronounced in the new-born and shows considerable variations independent of the age. One relation, however, is const. enough to serve as a diagnostic means. In children gaining in wt. the amylolytic power is increased after meals; in those not gaining or losing wt. the reverse is the case. With regard to starch there is no difference between the amylolytic power of infant and adult saliva. The latter, however, attacks compact lumps, e. g., boiled potato, more energetically than the former. Addition of boiled adult saliva to fresh infantile saliva increases its digestive power for potato lumps. The effect is independent of the reaction of the saliva and is apparently not due to activation by CNS compds, which are also present in infant saliva.

Muscle fatigue. V. The lactic acid content of muscle during prolonged activity under physiological conditions. FRITZ BÜRGEL. *Z. Biol.* **81**, 253-62(1294); *Ber. ges. Physiol. explil. Pharmacol.* **29**, 226.—Unlike the isolated muscle the active muscle *in situ* does not show any accumulation of lactic acid. This is attributed partly to diffusion into the blood, partly to carbohydrate formation.

MARY JACOBSEN

Energy metabolism of normal new-born babies with special reference to the influence of food and of crying. J. R. MURLIN, RUTH E. CONKLIN AND M. ELIZABETH MARSH. *Am. J. Diseases Children* **29**, 1-27(1926).—234 observation periods on fifty new-born infants, from 6 hrs. to 15 days, have been made with a respiration app. with a max. error in the measurement of oxygen of 5%. The basal metabolism of resting infants averaged 6.67 cal. per hr., or 2 cal. per kg. and 29.16 cal. per sq. m. per hr. The respiratory quotient ranged from 0.66 to 1.16. The av. of all quotients is from 0.79 the first 24 hrs. to 0.75 the fourth, thence gradually upward to 0.85 on the ninth. The basal heat production is highest in the second 24 hrs. From this point it falls gradually on the basis of the surface to the sixth day, from which point it again rises steadily. Statistically, the surface area is a better measure of basal metabolism than body wt. There appears to be no correlation between heat production and pulse rate. Active healthy crying requires just as much again expenditure of energy as the basal (sleeping) metabolism. The accurate respiratory quotient is an index of the state of nutrition. The dynamic action of ordinary feedings or of supplementary feedings within the first eight days is very small. The largest recorded was 12% from a feeding of 10% lactose or dextrose.

I. NEWTON KUGELMASS

The respiratory metabolism in infancy and childhood. S. Z. LEVINE AND J. R. WILSON. *Am. J. Diseases Children* **31**, 324-34(1926).—The minimal energy requirement in 5 normal children was found to be within about 6% of the standards established by Benedict and Talbot. Body surface and body wt. were equally good standards for predicting the basal metabolism in these normal children of normal stature. In one overweight girl, the body surface was a better criterion for prediction than the body wt. In one diabetic boy, the lowering of the basal requirement was proportional to the degree of malnutrition. In one girl, the basal metabolism was not increased five hrs. after a light meal.

I. N. K.

The respiratory metabolism in infancy and childhood. II. Ketosis and the respiratory exchange in children. J. R. WILSON, S. Z. LEVINE AND HELEN RIVKIN. *Am. J. Diseases Children* **31**, 335-56(1926).—The results are based on data derived from measurements of the respiratory exchange of six children during the ketosis induced

by fasting and by high-fat and low-carbohydrate diets. A significant ketonuria appears in children at consistently lower metabolic fatty acid-glucose ratios than in adults. Children excrete a relatively greater quantity of ketone bodies at a given metabolic ratio above the threshold of ketosis. This fact may explain the more rapid development and the greater severity of ketosis in children than in adults. Children do not necessarily oxidize foods in the proportions contained in the diet; hence dietary data are unreliable in correlating the ketogenic balance with ketone body excretion. Normal children oxidize a higher proportion of carbohydrate and a lower proportion of fat than they receive in their diets. Sugar and CO_2 content of the blood fall during fasting and during the ingestion of low-carbohydrate, high-fat diets. The tendency of children to develop ketosis may be counteracted by giving diets high in carbohydrates and low in fat, especially in conditions associated with an elevated metabolism. I. N. K.

Blood as a physicochemical system. III. Deductions concerning the capillary exchange. L. J. HENDERSON AND C. D. MURRAY. *J. Biol. Chem.* 65, 407-17(1925); cf. *C. A.* 18, 2368.—Curves are given, constructed from known data, which give the specific diffusing capacities of the lung and tissue capillaries at different points of the arterio-venous cycle. It is assumed that the gaseous exchange between alveolar air and blood and between blood and the tissues is a simple diffusion process, that the rate of O_2 diffusion is detd. by the difference in its tension in the alveoli and the blood and that the tension of O_2 in the tissues is zero. It is calcd. that during moderate work the number of physiologically active capillaries in the lung are increased at least 5 times and those in the tissues to a still greater extent. This opening of the capillaries is accompanied by a like increase in the total flow of blood; this readjustment, however, will involve but little change in the blood flow per capillary and, therefore, in the compn. of the blood and in the physicochem. conditions of the environment of the cells.

A. P. LOTHROP

Oxygen exchange, blood and the circulation. A coördinated treatment of the factors involved in oxygen supply on the basis of the diffusion theory. C. D. MURRAY AND WM. O. P. MORGAN. *J. Biol. Chem.* 65, 419-44(1925).—The process of O_2 exchange is a system of 6 variables: (1) metabolic rate, (2) O_2 capacity of the blood, (3) O_2 satn. of arterial blood, (4) O_2 satn. of venous blood, (5) p_{H} of the serum, and (6) tension of O_2 in alveolar air or tissues. Curves are given, constructed from known data, showing the relationships between the 1st 4 variables which result from certain combinations of the last 2. The "specific diffusing capacity" [$\text{SDC} = \text{DC}/(\text{BF} \times \text{Hgb})$] is defined as the diffusing capacity of a capillary region, per l. of flow per min. (BF) of a blood of a certain total O_2 capacity (Hgb). Its reciprocal is called the "specific hemoglobin flow." This latter new term has been introduced to emphasize the important physiol. adjustment of the product, blood flow times O_2 capacity, to capillary area. "In that the discussion and the treatment of the various factors aim at giving a fairly complete description of the conditions for the diffusion and transport of O_2 in the body, it is hoped that this description may afford a basis for testing the physiol. role of the diffusion process and the distribution of physiol. function among the various factors under all sorts of environmental and pathol. states."

A. P. LOTHROP

The carbon dioxide excreted in one minute by one centimeter of nerve fiber. G. H. PARKER. *J. Gen. Physiol.* 9, 191-5(1925); cf. *C. A.* 20, 230.—One cm. of nerve fiber from the lateral-line nerve of the dogfish excretes about 4.2×10^{-4} mg. CO_2 per min. av.

C. H. R.

The shape of the mammalian erythrocyte and its respiratory function. E. PONDER. *J. Gen. Physiol.* 9, 197-204(1925).—A math. analysis of the form of the erythrocyte is given and the effect of form on respiration discussed.

C. H. R.

The form of occurrence of uric acid in urine. P. FLEURY. *J. pharm. chim.* [8], 2, 194-203(1925).—A succinct résumé of the facts made known by Ducung (1892), Rangier (*C. A.* 18, 1309), Maillard (*C. A.* 18, 2716) and Chelle and Rangier (*C. A.* 19, 850), enabling a rapid and exact detn. of uric acid in urine. The nature of the group combined with uric acid and rendering it sol. in normal urine is still unknown.

F. A. CAJORI

The metabolism of the healthy and the diseased organism after parenteral injections of milk. W. BUOMO. *Arch. Gynäkol.* 126, 291-309(1925).—The parenteral injection of milk in normal dogs increased the elimination of N, proportional to the amt. of milk used. The elimination of P in the urine was slightly increased. The same results are obtained in animals with slight infections not accompanied by an increased elimination of N and P before the injection. In infected animals in which there was an increased elimination of N, the milk injections were followed by a decrease in N and P elimination. Most gynecologic patients reacted to the milk injections with a marked persistent lowering in N and P elimination accompanied by clinical improvement. When the milk injections were not followed by a lowering of N and P elimination, there was no clinical improvement and in 1 case there was an aggravation of the condition.

HARRIET F. HOLMES

The importance of chemico-physical changes in the blood and blood sugar content curve in the female organism during pregnancy and outside. 1. In physiological conditions. 2. Hyperemesis gravidarum. E. FREY. *Arch. Gynäkol.* 126, 383-487 (1925).—A chem. study was made of the blood of women in various stages of pregnancy and during and after the puerperium. The sugar content of the blood was detd. before and after the oral administration of 20 g. glucose and compared with the findings in non-pregnant women. Many tables and graphs are presented. In the first months of pregnancy there is a low sugar content of the blood at the level of the lowest normal values. Administration of glucose is followed by slighter hyperglucemia, with a delayed return to normal glucose content. This indicates only a slight store of reserve glycogen. In the last months of pregnancy there is a disturbance of intermediary metabolism with a decreased breaking up of amino acids, leading to a high amino acid content in the blood and a decreased amt. of urea. The findings with regard to amino acids and urea indicate a relative insufficiency of the liver. As pregnancy advances there is a decreased hemoglobin content. At delivery the changes of the last months of pregnancy are increased. Soon after delivery, residual N and its components return to normal values. The serum globulins, however, are still more increased than at delivery and the sinking of the red blood cells is also increased. While hyperemesis gravidarum is probably a neurosis rather than a toxemia of pregnancy or a disturbance of metabolism, the glucose test gives a good indication as to whether a dangerous functional disturbance threatening life is present. Residual N value over 60 mg. and a hyperglucemia lasting over 175 min. after the administration of 20 g. glucose indicates a severe and dangerous hyperemesis.

HARRIET F. HOLMES

Further study of basal metabolism in pregnant women. E. KLAFFEN AND L. STECHER. *Arch. Gynäkol.* 126, 541-52(1925).—Detns. of basal metabolism in pregnant women indicated normal O consumption in most multigravidae and normal primi gravidae, and a lowering of the sp. dynamic protein quotient in too young or too old primigravidae and also in cases showing the dropsy or nephropathy of pregnancy.

HARRIET F. HOLMES

The relation of ovarian function to the calcium content of the blood serum. A HEYN AND K. HAASE. *Arch. Gynäkol.* 126, 646-70(1925).—Detns. were made of the Ca content of the blood in 89 women. Ca values higher than normal were found in cases of ovarian insufficiency, reaching the greatest height in functional amenorrhea. The natural menopause was followed by a lowering of the Ca content. Castration was followed by a lowering of the Ca content, which, however, regained the normal height within a year. It is improbable that the ovary has a direct influence on the Ca content of the blood.

HARRIET F. HOLMES

Physicochemical changes in the blood after experimental fever. H. BRUNETTI AND L. ELEK. *Z. ges. expil. Med.* 47, 265-75(1925).—A study was made in 21 patients of the physicochem. changes in the blood plasma after large doses of unspecific vaccines. There was no parallelism between the amt. of vaccines injected and the degree of fever. The greatest febrile reaction was observed in cases of splenomegaly, indicating the important role of the reticulo-endothelial app. in the immunobiological protective reactions. Especially high fibrinogen values were found in 2 cases of lymphogranuloma. The albumin values in percentage of total protein showed a decrease in diseases of the liver and an increase where the liver was normal. The H-ion concn. remained const. in 2 cases with a fever reaction and in 7 other cases rose from p_H 0.03 to 0.09.

HARRIET F. HOLMES

The behavior of protein and its fractions and also the chlorides and viscosity in venous and arterial plasma. H. BRUNETTI AND L. ELEK. *Z. ges. expil. Med.* 47, 277-84 (1925).—Comparative study of venous and arterial plasma showed in the venous blood a 1.59% higher protein content, a 3.57% higher albumin content as expressed in %

of total protein and higher specific viscosity of 11.06. The fibrinogen values were the same in both venous and arterial blood. In the arterial blood there was a higher chloride value of 12.36 mg. %.

HARRIET F. HOLMES

The effect on yeast fermentation of sugar of constituents of the urine and alcohol-free extracts of organs. A. GIGON AND H. ODERMATT. *Z. ges. expil. Med.* 47, 294-308 (1925).—The fermentation of a glucose-yeast mixt. is increased by the addn. of small quantities of human urine. Urine loses this activating power on heating, indicating that it is due to substances of a vitamin-like nature. The fermentation is increased also by glycocoll, sulfates and NaH_2PO_4 , is not affected by blood and is delayed by NaCl , urea, uric acid, phosphoric acid, phosphates, CaO and alc. Glucose added to the urine decreases its activating action, while an addn. to the urine of olive oil, casein or levulose has no effect. After the use of alc. in excess the enzyme-activating power of the urine is increased and is most marked 1-2 hrs. after taking alc. It is probable that in alcoholism the elimination of certain vitamin-like substances from the body by the alc. is the cause of various symptoms such as polyneuritis. Protein-free exts. from the motor nerve roots both in man and the dog have more effect in accelerating fermentation than protein-free exts. from the sensory nerve roots, indicating that the supply in vitamin-like substances is smaller in the sensory than in the motor roots.

HARRIET F. HOLMES

Water metabolism in diabetes mellitus and the effect on it of insulin. III. O. KLEIN. *Z. ges. expil. Med.* 47, 309-24(1925); cf. C. A. 19, 1597.—In severe diabetes the administration of large amts. of H_2O causes a retention of H_2O with hydremia. The administration of NaCl and carbohydrates with H_2O causes no retention of H_2O , while carbohydrates with H_2O cause a mobilization of H_2O with diuresis. In severe cases of diabetes that have been under insulin treatment for some time the administration of large amts. of H_2O leads to H_2O and NaCl diuresis and a concn. of the blood. When carbohydrates or NaCl is given with the H_2O , there is a retention of H_2O .

HARRIET F. HOLMES

The peptidase content of the paralytic with experimental malaria and other infections. H. PFEIFFER, F. STANDENATH AND R. WEEBER. *Z. ges. expil. Med.* 47, 386-405 (1925).—The peptidase content of the serum of a paralytic does not differ from that of a healthy individual of the same age. If a paralytic is infected with malaria the peptolytic index of the serum rises to 10-20 times the former value. Other febrile conditions such as erysipelas and advanced pulmonary tuberculosis also increase the peptolytic index of the serum. These changes in peptolytic index are not dependent on changes in H-ion concn. brought about by fever. The antitryptic titer of the serum follows the peptolytic index but the variations are not so great. The peptidases of the serum rise with the fever, and there is a decreased elimination of them in the urine at this time; the peptolytic index of serum and urine vary in the inverse direction. H. F. H.

The displacement of ions in the blood and its relation to kidney functions in pregnancy. D. ADLERSBERG AND F. KANDERS. *Z. ges. expil. Med.* 47, 466-86(1925).—In 25 normal pregnant women the CO_2 tension of the alveolar air and the alkali reserve of the blood were slightly decreased at all stages of pregnancy. The p_{H} of the blood, while within normal values, was displaced to the side of acidity. A displacement of the normal equil. was noted in the direction of hyperchloremia with hydremia or hypocarbonatemia. The kidney of pregnancy shows a tendency to a retention of chlorides and an increased excretion of carbonates.

HARRIET F. HOLMES

The content of the blood in amino acids and polypeptides in pregnancy at delivery and after delivery. H. SCHLOSSMANN. *Z. ges. expil. Med.* 47, 487-502(1925).—In pregnancy and in the puerperium there is an increase in the blood of residual N, amino acid N and polypeptide N. In the first days after delivery all of these N values increase, the polypeptide N to the greatest extent. In the toxemias of pregnancy the amino acid N is not increased but the polypeptide N increase in the blood parallels the severity of the clinical process. After venesection in severe toxemias of pregnancy there is an increase of polypeptide N in the blood, indicating that in toxemias the content of polypeptic N in the edematous fluids and tissues is higher than that in the blood stream. The same is true of residual N. It is undecided whether the increase of the polypeptide N in the blood is a cause or a result of the toxemia of pregnancy.

HARRIET F. HOLMES

The demonstration of pancreatic lipase in the serum in diseases of the pancreas. V. JEDLIČKA AND V. KREISINGER. *Z. ges. expil. Med.* 47, 513-33(1925).—While serum does not inhibit the action of pancreatic lipase, the erythrocytes exert a certain inhibition, perhaps through their lipid stroma. It is improbable that pancreatic lipase can enter the blood stream from a functional disturbance of the pancreas without

anatomical lesion. The diastase content of the blood is more sensitive than the lipase content, but the impossibility of a quant. differentiation of serum and pancreas diastase makes the detn. of diastase of no special diagnostic value for the clinician in diseases of the pancreas.

So-called "melanosis" of the colon. G. O. E. LIGNAC. *Krankheitsforschung* 2, 162-74(1925).—This consists of a deposit of amorphous pigment in the mucous membrane of the large intestine, appendix, etc., apparently following the presence of blood in the intestinal tract. Analysis shows no metal in the pigment; it is insol. in HCl, HNO₃, or H₂SO₄. It is resistant to post-mortem decay. In fuming HNO₃ it loses color like melanin of the skin, but it is less easily oxidized and absorbs Ag from AgNO₃ less readily, so "melanosis" is a misnomer. It is related to the blood pigments but is distinct from all now known.

The influence of calcium salts on the action of porphyrin in the animal body. G. O. E. LIGNAC. *Krankheitsforschung* 1, 177-93(1925).—Paramecia, treated with hematoporphyrin, die if exposed to light; erythrocytes similarly treated hemolyze. If 2.5 mg. hematoporphyrin-HCl is injected into white mice, they become very uneasy if exposed to sunlight and die in about 3 hrs. There is hyperemia of ears, nose and tail; the lungs are gorged with blood and there are pathological changes in the heart. If they are kept in the dark these changes do not occur. This suggests the liberation of poisons in the skin by the action of light. If the hematoporphyrin is followed by an injection of CaCl₂, death may not occur and all symptoms are milder. L. suggests that hematoporphyrin forms a metallic complex with Ca, which ppts. in the blood or tissues; or else the poisoning effect of the Ca is antagonistic. Ca may be used for congenital porphyrinuria, etc.

Changes in the reaction of skin after repeated treatment of the same spot. L. TÖRÖK, E. LEINER AND F. URBÁN. *Krankheitsforschung* 1, 371-406(1925).—If small quantities of morphine, horse serum, caffeine, etc., are injected into the skin and the injection is repeated as soon as the swelling has disappeared, the first 2 or 3 injections produce a progressive increase in swelling and inflammation, followed by a sudden decrease in sensitiveness to the treatment. Chemicals which cause inflammation have at first a greater and then a diminished effect, if time is allowed between applications for the swelling to disappear. Heat, cold, pain, or other phys. treatment have analogous effects. Injections of blood, washed blood cells, hemolyzed blood, or 4% oxy-hemoglobin cause no swelling; but if they are injected before morphine or histamine they diminish the swelling caused by these. Most of the expts. were on normal human skin.

Poisoning produced by protein decomposition products. H. PREIFFER. *Krankheitsforschung* 1, 407-44(1925).—The products (proteoses) may be absorbed from the intestine in cases of intestinal intoxication; or may be produced in the body by the decay of cells or tissues, as in malaria, abscess, bacteriolysis, etc.; by anaphylactic shock; or by the effects of radiant energy. The various sources and effects are reviewed in detail.

Changes produced by syphilis in the distribution of serum lipoids. E. K. WOLFF AND K. FRANKENTHAL. *Krankheitsforschung* 1, 445-56(1926).—A Wassermann negative serum has 87% of the cholesterol in the globulin fraction and 13% in the albumin; a positive serum has 79% in the albumin and only 21% in the globulin; (NH₄)₂SO₄ was used to ppt. the fractions. Pptn. with ZnSO₄, slightly acidified, shows practically 100% cholesterol in the globulin for a negative serum, 86% for a positive. Lipoid P is mainly in the albumin fraction for a positive serum, but largely in the globulin for a negative. Tables are given showing the results of a series of expts. and the results of other investigators are compared with these.

The action of ammonium hydroxide and ammonium chloride on the movement of the stomach. W. W. PRĄDZICZ-NEMINSKI. *Z. Biol.* 83, 454-62(1295).—NH₄OH and NH₄Cl soln. when poured into the stomach of a dog with a fistula calls forth movements. There is an increase in the amplitude of the periodical movements of the empty stomach and a change in the time for their appearance. When a sufficient amt. of these stimulants is applied, the stomach is put in a state refractive to succeeding impulses. The organ attempts, at the same time, to maintain normality. The similarity of the action of the 2 salts indicates that the effect depends on the cation, NH₄, and not on the anions, OH or Cl.

Coagulation of protein in drops. VII. Study of precipitation reactions by means of the drop method. V. MORAŠKO. *Biochem. Z.* 159, 280-5(1925); cf. Bečka and Simánek, *C. A.* 19, 2213.—In an attempt to classify the serum used in a precipitin reaction according to the species from which it came, the nature of the ppt. obtained is

compared with the ppt. formed in a drop of the serum by reagents, such as phenols, mineral acids, organic acids, HgCl_2 , CuSO_4 and FeSO_4 . These ppts. seem to be characteristic enough in appearance properly to classify the serum. W. D. L.

Physicochemical aspects of hemolysis. IV. The relation of the acidity of phosphate buffers to biologic hemolysis. REED ROCKWOOD. *J. Immunol.* **10**, 741-75 (1925); cf. *C. A.* **19**, 317.—Red cells have a strong power of altering acidity, even in isotonic buffer solns. In solns. satd. with CO_2 change in H-ion concn. due to the cell is much less marked. The effective range of H-ion concn. for biologic hemolysis is from about 6.0 to 8.3, with a broad optimum near neutrality. No significant change in the morphology of the cell occurs except in extremely acid solns. The effect of acid on amboceptor is similar to that of hemolysis as a whole. The hemolytic power cannot be restored entirely by changing acidity. Too strong acid destroys, not merely inactivates, part of the amboceptor. Complement is partly destroyed, but more largely merely inactivated. The point of max. combination of cell and amboceptor is well toward the acid side, and the amt. of combination gradually decreases as neutrality is approached. In extremely acid or alk. medium the complement is not present, either in the cell or in the supernatant fluid in a form in which it can be reactivated by neutralization. Complement can be split by HCl over a range of at least p_H 5.8-6.4. The addn. of alkali in the standard method makes it strongly alk., but keeps it in the range of optimal hemolysis. The complement can still be split, however, if less alkali is used. Filtration of the split complement increases the final alky., because of the acid mixt. which remains on the filter paper. The mixt. of mid piece and end piece which have been reunited is distinctly more alk. than a mixt. neutralized before centrifuging and washing the globulin. The results of complement splitting by CO_2 are variable, depending more on the heaviness of the protein cloud than on actual acidity. Failure is frequent at acidities which cause splitting in the case of HCl. Splitting of complement by dialysis was successful in only 1 case. In all the attempts there was no great change in the reaction of the solns. An attempt to split complement by acid phosphate solns. in the presence of an excess of amboceptor was not successful. A group of expts. based on those of Bronfenbrenner and Noguchi (*C. A.* **7**, 150) on complement splitting was carried out. With the use of HCl the acidity in the different tubes is similar, whether complement is split or not. Bubbling CO_2 through for 2 min. does not increase acidity. Reactivation of the HCl end piece depends on sp. factors, not on changes of acidity. The same is true of the end piece split by CO_2 . F. R. LONG

Antigenic character of heated protein. J. FÜRTH. *J. Immunol.* **10**, 777-89 (1925).—Heating blood serum or cryst. egg albumin to 100° creates a new antigenic specificity. Heating serum to 70° partly transforms it into this new antigen. Antisera obtained by injecting serum heated to 100° ppt. the antigen used strongly, but cause weak pptn. of unheated protein. Anti-cocto-serum of rabbits or guinea pigs prepd. with the serum of 1 species, heated to 70 – 100° , ppts. serums from other species. Antibodies are not produced by rabbits and guinea pigs when directly injected with their own heated serums. The ppt. formed by cocto-antigen and its cocto-precipitin fixes complement. Heterologous cocto-antigen does not fix complement in the presence of cocto-precipitin. There is a close parallelism between the severity of Arthus reaction with cocto-antigen and the cocto-precipitin content of the serum. Serum heated to 100° for 5 min. produces anaphylactic shock and incites uterine contraction in guinea pigs sensitized to cocto-antigen. E. R. LONG

Temperature increase from products of bacterial autolysis. JOSÉ CARRA. *Z. Immunitäts.* **43**, 464-9 (1925).—At the beginning of autolysis of staphylococci hyperthermic substance alone is produced. With the progress of autolysis, increasing amts. of substance causing a decrease in temp. are produced. E. R. LONG

The action of Röntgen, radium and ultra-violet rays on the components of the Wassermann reaction. GÜNTHER BRANN. *Z. Immunitäts.* **44**, 27-32 (1925).—Röntgen rays are practically without action on negative or positive serums in the Wassermann reaction. Occasionally a slight weakening of positive serums is caused. Röntgen irradiation has no effect on cholesterolized beef heart ext. or on complement, as far as the Wassermann reaction is concerned. Ra irradiation of complement (guinea-pig serum) weakens or destroys it. It has no action on human serums, either positive or negative. Irradiation by quartz lamp rays destroys complement, but has no effect on cholesterolized antigens or Wassermann negative or positive human serum. E. R. LONG

The problem of artificial complement. J. BORN. *Z. Immunitäts.* **44**, 33-43 (1925).—The artificial complement of Liebermann (MeOH soln. of Na oleate and CaCl_2) can replace natural complement in the hemolytic system. E. R. LONG

The theory of the colloid reactions in the cerebrospinal fluid. H. A. KREBS. *Z. Immunitäts.* **44**, 75-104(1925).—Negative suspensoids in the presence of cerebrospinal fluid proteins form an adsorption compd. with the globulin. This compd. acts as an amphoteric electrolyte. Its flocculation depends on the H-ion concn. at the isoelec. point. The isoelec. point is higher the smaller the globulin content of the compd. All conditions modifying the globulin content or the H-ion concn. of the medium modify flocculation. E. R. LONG

Investigations on lysocithin. I. The significance of lysocithin in the pathogenesis of intoxications and infections. S. BELFANTI. *Z. Immunitäts.* **44**, 347-63(1925).—Lysocithin (the product obtained from the action of lecithinase on lecithin) from egg or brain is a strongly toxic substance which dissolves erythrocytes and leucocytes and injures the brain and its capillary endothelium, with the production of edema and hemorrhage. Another group of lysocithins, in the pancreas, salivary glands and other tissues are inactive in the body, because held in check by antagonistic substances, particularly cholesterol. It is possible that the endogenous or exogenous enzymes, from bacteria, e. g., are capable of making this group of lysocithins toxic. **II. The action of lysocithin in vivo on animal tissues.** GUIDO GUERRINI. *Ibid* **45**, 249-68.—Lysocithin, from the poison of *Crotalus terrificus*, the substance "Y" of Belfanti and the poison of *Lachesis*, all have the same action on animal tissues. They are capillary poisons, causing extensive hemorrhage wherever injected, reminding one of the hemorrhagic septicemias. E. R. LONG

Influence of benzoin on the serologic activity of lipoids, with particular reference to the serum diagnosis of syphilis. T. OHASHI. *Z. Immunitäts.* **44**, 377-402(1925).—Mixts. of lecithin and benzoin increase the speed of serologic flocculation. Sensitiveness in the reaction with human serum is inversely proportional to the amt. of lecithin. Too small lecithin content is to be avoided in the serum diagnosis of syphilis. The best mixt. is 1 cc. 2% lecithin and 0.3 cc. 10% benzoin. This mixt. is diluted first with 3 parts physiol. salt soln. and after 10 seconds with 16 parts more. The activity of the mixt. decreases on standing. Increasing the benzoin increases sensitiveness, but decreases specificity. The addn. of cholesterol to lecithin decreases or increases activity according to the concn. Excess of cholesterol increases sensitiveness without avoiding non-specificity. Suitable quantities of cholesterol act as protective colloid, in relation to benzoin flocculation, while in stronger concns. cholesterol acts as a flocculating agent. E. R. LONG

Active immunization with non-toxic culture filtrates. II. Dysentery bacillus Shiga Kruse. R. KRAUS, T. AWOKI AND B. KOVACS. *Z. Immunitäts.* **45**, 42-8(1925). cf. Kraus and Imai, *Wien. klin. Wochschr.* 1925.—In the formation of dysentery toxin intermediate substances are produced, which are non-toxic, but on injection lead to sp. antitoxic immunity. E. R. LONG

Immunization with non-toxic bouillon culture filtrates of diphtheria and tetanus bacilli. MIZUHO NAKATA. *Z. Immunitäts.* **45**, 402-5(1925).—It was not possible to develop diphtheria and tetanus antitoxin by the use of non-toxic bouillon culture filtrates from a number of strains of tetanus and diphtheria bacilli. The results were in sharp contrast to those obtained by Kraus, *et al.* (preceding abstract) with non-toxic filtrates from dysentery bacilli. E. R. LONG

Dry complement and its use in the Wassermann reaction. V. I. ROMANOV. *Z. Immunitäts.* **45**, 74-80(1925).—Fresh guinea-pig serum dried at reduced air pressure retains its complementary action at least 1 month. The better it is dried the better it retains its activity. The titer of the dried complement, however, is somewhat weaker than its titer before drying. Weakly positive serums may fail to react with the dried complement. E. R. LONG

Active immunization against diphtheria by the use of toxoids. II. St. BÄCHER. R. KRAUS AND E. LÖWENSTEIN. *Z. Immunitäts.* **45**, 86-92(1925).—By treating formal toxoids with weak AcOH, preps. are obtained which retain their capacity to unite with antitoxin and incite immunity, but lead to little infiltration. Toxoids treated with alc. also retain their antigenic activity, but the reactions in guinea pigs are not appreciably lessened. E. R. LONG

Toxoids. III. Active immunization against venom. STEFAN BÄCHER, RUDOLF KRAUS AND ERNST LÖWENSTEIN. *Z. Immunitäts.* **45**, 93-6(1925).—Combined action of formalin and high temp. on venom (*Lachesis jararaca*) produced non-toxic toxoids which retained antigenic activity. The component of the poison causing hemorrhage and necrosis is little influenced by this treatment, and immunization with toxoids confers no protection against this effect. E. R. LONG

The Wassermann tuberculosis antigen. HANS RITTER AND HEDWIG KÖSTER.

Z. Immunitäts. 45, 111-24(1925).—Pinner (*Z. Tuberkulose* 41; cf. *C. A.* 19, 2979) is not correct in his statement that the activity of the Wassermann tuberculous antigen resides in the alc.-sol. fraction. It is true that alc. extn. injures the antigen, but the complement-fixing reaction obtained with the ext. is unspecific and does not depend on the active substance of the Wassermann antigen. E. R. LONG

Antigenic function of the Forssman lipoids and other lipid haptenes. R. DOERR AND C. HALLAUER. *Z. Immunitäts.* 45, 170-90(1925).—Rabbits immunized with a mixt. of alc. horse kidney ext. and foreign serum furnish 2 different antibodies, the Forssman amboceptor and a precipitin for foreign protein which are completely independent and can be sepd. from the immune serum by sp. combination with 1 of the 2 antigens. Activation of the Forssman lipoids with the production of complete antigen is not brought about through foreign serums, but occurs completely with aq. extn. of organs of the same species. Activation does not occur with intact foreign erythrocytes, but does occur with the dissolved protoplasm of such cells. Dissolved erythrocyte protein from erythrocytes of the same species is also active. E. R. LONG

Metal salt therapy. L. E. WALBUM. *Z. Immunitäts.* 43, 433-64(1925).—There is a relation between at. wt. and the action of metallic salts on the formation of agglutinins and amboceptor and bacteriocidal substances and blood lipase. The injection of small quantities of Mn salts facilitated the destruction of toxins. Injection of Cs and Ir protected mice against infection with certain bacteria of the paratyphoid group, but was ineffective against streptococci. Animals infected with tubercle bacilli and later injected with metal salts of many varieties died of tuberculosis intoxication but not of tuberculous infection. Al and Mn were most active in this manner; Au was less active and Cs least active. Studies on tuberculous guinea pigs showed that the concn. of metal salts required for therapeutic action is lower than that required to stimulate bacterial growth, and coincided with the optimum concn. for the stimulation of antibody production. Larger doses of the metallic salts favored the growth of the bacteria in the body, and decreased antibody production. E. R. LONG

Metal salts and antibodies. S. SCHMIDT. *Z. Immunitäts.* 45, 305-22(1925).—The results of Walbum (cf. preceding abstr.) are confirmed. $MnCl_2$ stimulates antibody production in the anti-diphtheria immunization of horses and goats. The injection of Ba and Pb favors antitoxin production in anti-diphtheria immunized sheep. All metals of the Ca and Mg groups favor the production of diphtheria antitoxin in horses, except Sr. The metals probably act by setting free antibodies already formed, rather than by stimulating the formation of new ones. E. R. LONG

The influence of organ extracts on complement fixation brought about by antigen-antibody reactions. KAZUO HOTTA. *Z. Immunitäts.* 45, 323-33(1925).—Alc. organ exts. favor sp. complement fixation brought about by antigen-antibody reactions. Increase in hemolysis is caused by alc. alone, but alc. organ exts. act more energetically. Alc. and alc. organ exts. are effective through their protein-pptg. power. They favor anticomplementary action in general by favoring globulin alteration. These investigations lend no support to the theory that the blood changes in syphilis consist in the simultaneous presence of spirochete antigen and antibody in syphilitic blood, and that the addn. of organ ext. leads to their reaction. E. R. LONG

The use of benzochol extracts in the Wassermann reaction. KAZUO HOTTA. *Z. Immunitäts.* 45, 442-52(1925).—The addn. of benzoin to cholesterolized beef heart exts. increased the activity of the latter, so that the reaction occurred with smaller amts. than are ordinarily used. These benzoin-cholesterol exts. (benzochol exts.) must be dild. 10-20 times before use. Although spontaneous flocculation occurs, such ext. dilns. are suitable for use for weeks. The reactive capacity in these flocculated specimens is bound with the ppt. The use of benzoin in the manner described is recommended for the Wassermann reaction, in view of its action in promoting sensitiveness. E. R. LONG

Experiments on the promotion of hemolysis. KAZUO HOTTA. *Z. Immunitäts.* 45, 453-60(1925).—The addn. of organ exts. to a mixt. of sheep blood, amboceptor and complement under certain conditions furthers hemolysis. This effect is particularly noticeable in those tubes into which the contents are blown, rather than allowed simply to run in. Blowing air through the tubes has the same effect. The promotion of hemolysis in these instances is probably to be attributed to the CO_2 content of the air blown in. Small amts. of HCl have the same action. Apparently organ exts. exert an enhancing effect on hemolysis when the medium is acid. E. R. LONG

Some effects on the flocculation and turbidity reactions used in the serum diagnosis of syphilis. ALFONS HILPERT. *Z. Immunitäts.* 45, 461-77(1926).—The addn. of guinea-pig serum in the Sachs-Georgi reaction usually weakens the reaction, but occa-

sionally strengthens it. The addn. of CaCl_2 has in general the same effect. The addn. of guinea-pig serum usually inhibits the reversible early flocculation. This is significant in view of the fact that the Wassermann reaction may be negative in spite of intense flocculation reaction. Inactivated serums are less sp. than active serums in turbidity reactions. The non-sp. reaction with inactivated serum can be prevented by the addn. of soda in 10% salt soln. Soda-salt addn., however, weakens or prevents the reactions characteristic for syphilis. Ten % salt soln. alone weakens reaction capacity to some extent.

E. R. LONG

Precipitin of hemoglobin. TETSURO ISHIKAWA AND KAKUZO SAKURABAYASHI. *Tôhoku J. Exptl. Med.* 6, 395-8(1925).—The hemoglobin precipitin is formed exclusively from the protein part of the hemoglobin.

ALFRED N. RICHARDS

Bismuth in the treatment of syphilis. R. J. G. PARNELL. *J. State Med.* 34, 49-57 (1926).—Observations of treatment are made over periods of one and two years, respectively. Injections of metallic Bi cream were given into the buttock, care being taken not to inject into the blood stream, for metallic Bi is very toxic if introduced into the circulation. Metallic Bi cream is not a substitute for drugs of the arsphenamine type. It would appear to occupy a half-way position between Hg and neoarsphenamine. Compared with Hg it is far less toxic and of greater clinical therapeutic value; it appears to affect the serum Wassermann to a greater extent. It is valuable in cases unsuitable for arsenical therapy. Where prodromal treatment is desirable before establishing arsenical therapy Bi is safe and efficacious. Bi appears to have especially beneficial effects in glossitis and chronic leucoplakia of the mouth. It is tolerated well by cerebrospinal cases, and is given safely in cases with arsenical jaundice. In latent syphilis it appears to be the equal of arsphenamine and neoarsphenamine in its influence on the Wassermann reaction. In adjuvant treatment Bi should replace the use of Hg.

GEO. R. BANCROFT

Variations in physiological action of morphine derivatives with diverse substituent groups. A. ZAMPARO. *Loll. chim. Farm.* 64, 385-90(1925).—A crit. review of the physiol. action of morphine and its Me, Et, benzyl and Ac derivs. Substitution in a group (such as hydroxyl) modifies or suppresses its contribution to the general properties of the substance. The group in question functions either by attaching the mol. to the tissue, or else by producing a sp. effect after such attachment has been brought about by another group.

B. C. A.

Investigations of the action of narcophine on the digestion of meat in dogs. ED GARD ZUNZ. *Arch. intern. pharmacodynamie* 30, 1-63(1925); cf. *C. A.* 17, 1074, 2004 - Narcophine, which contains 29.28% morphine and 42.58% narcotine, was tested for possible synergistic effect on the digestive tract of the dog. Narcotine distinctly diminishes the emetic and purgative action of morphine in dogs. The general condition of the animals was more like that produced by opium minus morphine than by either complete opium or morphine-HCl. The contents of fundus, pylorus and duodenum were collected separately and the simple proteins detd. in each part of the stomach; N in the following forms was detd. in all 3 regions: NH_3 , amines, albumin, proteoses pptd. by half satn. with ZnSO_4 in acid medium, other proteoses (peptones) pptd. by phosphotungstic acid but not by ZnSO_4 , material pptd. by neither of these reagents. The biuret test was performed on the end-filtrates. The av. time required for complete emptying of the stomach in normal dogs was 11 hrs. The times corresponding to doses of 4, 8, 12 and 16 mg. narcophine were 21, 24, 26 and 30 hrs., resp. Twenty-five hrs. was required after 5 mg. of morphine meconate, which had an actual morphine content of 3.31 mg., the morphine content of 12 mg. of narcophine being 3.53 mg. One of the most striking actions of narcophine is its prolonged closure of the pyloric sphincter. The stomach retains cooked meat for periods longer than normal, in proportion to the dose of narcop. $1\frac{1}{4}$ - $1\frac{3}{4}$ hrs. elapse, for 4-16 mg. doses, between the ingestion of meat and its initial entrance into the pylorus. The chyme enters the duodenum immediately

thereafter. The evacuation of the stomach into the intestine is retarded in proportion to the dose of narcophine. The action of the digestive juices is retarded. The av. metaprotein content of the various portions of the digestive tract is increased in proportion to the dose. The stomach averages less proteoses and more peptones and peptides than normally. The reverse holds for the intestine; these changes become more marked with increasing doses of narcophine. There is a tendency to increased formation of NH_3 and aliphatic amines in the stomach.

T. B. GRAVE

The action of the hypno-anesthetics on the electrocardiogram. HENRIJEAN AND R. WAUCOMONT. *Bull. acad. roy. med. Belg.* [5], 5, 300-10(1925).— CHCl_3 and chloral produce atrioventricular block and "nodol" rhythm; with artificial respiration the intoxication is very much slower. Ether leaves the original rhythm undisturbed, until the heart is nearly dead.

R. BEUTNER

Does insulin possess a cardiovascular action antagonistic to adrenaline? PLUMIER-CLERMONT AND L. CAROT. *Bull. acad. roy. med. Belg.* [5], 5, 554-64(1925).—Insulin, injected intravenously, does not influence the arterial pressure nor the heart beat; it does not change the action of adrenaline, in any respect.

R. BEUTNER

Clinical and pharmacological investigations on dismenol, a new preparation against dysmenorrhea. J. A. VAN DONGEN. *Nederland. Tijdschr. Geneeskunde* 69, II, 1520-5 (1925).—Dismenol, a mixt. of *p*-sulfamidobenzoic acid and pyrimidone, has been tried in 31 cases of menstrual pain; in 14 cases no result was seen; in the other cases some relief was obtained, but not more than with other analgesic drugs. In expts. on the isolated uterus of cats suspended in Ringer soln., according to Magnus' method, *p*-sulfamidobenzoic acid relaxed the uterus when in the state of contractions after secacornine was added.

R. BEUTNER

The treatment of furunculosis with stannoxyl. S. POLIAKOFF. *Nederland. Tijdschr. Geneeskunde* 69, II, 2524-7(1925).—Stannoxyl, a mixt. of Sn and Sn oxide, gives relief in cases of multiple pyogenic abscesses. The dose is 0.5 to 1 g. by mouth per day.

R. BEUTNER

New observations on the question of the effect of "thyreoidins" on alcoholic fermentation. II. L. P. ROSENOW. *Biochem. Z.* 160, 269-71(1925); cf. C. A. 20, 929.—Com. thyroid exts. *Bacteriology* (thyreoidin) were found to contain substances that stimulate the fermentation of sugar by yeast.

F. A. CAJORI

Habituation to alcohol in man. K. HANSEN. *Biochem. Z.* 160, 291-7(1925).—The EtOH content of the blood of men was detd. at intervals after the taking of 0.5 g. of EtOH per kg. body wt. The peak of the curves obtained tended to be lower as the individual became habituated, through daily use, to the dose of EtOH.

F. A. C.

The action of santonin on blood sugar. A. STASIAK. *Biochem. Z.* 160, 298-306 (1925).—Daily doses of 0.2 to 0.4 g. of the Na salt of *santonin* by mouth produced in rabbits a hypoglucemia, hypotonicity and muscular weakness. Histological examn. showed degenerative changes in the liver and to these changes is ascribed the hypoglucemia and other effects of the drug.

F. A. CAJORI

Pharmacological investigations on some new proteinogenous cholines. T. GORDON-OFF. *Biochem. Z.* 160, 451-63(1925).—Alanineacetylcholine, $\text{MeCH}(\text{NMe}_2\text{I})\text{CH}_2\text{OAc}$, leucineacetylcholine, $\text{Me}_2\text{CHCH}_2\text{CH}(\text{NMe}_2\text{I})\text{CH}_2\text{OAc}$, and other acetylated derivs. of choline and amino acids produced similar pharmacol. action on the isolated frog heart, rabbit intestine and guinea-pig uterus as acetylcholine. Non-acetylated derivs. did not show pharmacol. activity and neither acetylated nor non-acetylated derivs. produced pharmacol. effects when injected into the intact animal.

F. A. CAJORI

Calcium metabolism and adrenaline. TAKEO INOUE. *Tokyo Ig. Kw. Z.* 36, 544-85(1922); *Japanese J. Med. Sci.* 2, 14-5(1924).—Subcutaneous injection of adrenaline in normal man caused an increase in the hourly excretion of Ca. Later there was a diminished Ca excretion. P excretion was usually increased following adrenaline, whereas NaCl excretion was diminished.

F. A. CAJORI

The chemotherapy of local suppuration: acriflavine and boric acid compared. J. G. GRAHAM. *Brit. Med. J.* 1925, II, 826.—A case with extensive burns was partly treated with both agents. Such better effects were obtained with the former, that the boric acid was discontinued.

A. T. CAMERON

The strength of insulin preparations. G. A. HARRISON, R. D. LAWRENCE AND H. P. MARKS (with introduction by H. H. DALE). *Brit. Med. J.* 1925, II, 1102-7.—Rabbits were prepd. for test by withholding food (but not H_2O) for 24 hrs. The av. reduction in the blood sugar was detd. over a period of 5 hrs. following injection (hourly detns.) and expressed as a percentage of the initial blood sugar. Six animals are desirable, but the hourly samples (0.2 cc.) can be added and 1 detn. made. In this way different samples can be accurately compared. Clinical tests on diabetics with different

samples standardized by the above procedure gave results in good agreement, the sugar curve following injection being used as criterion.

A. T. CAMERON

The thyroid and manganese treatment. Its influence on abnormal blood pressure. (Interim report.) H. W. NORR. *Brit. Med. J.* 1925, II, 1209-12; cf. *C. A.* 19, 3113.—Chiefly clinical.

A. T. CAMERON

The effect of pancreas preparations by the mouth upon carbohydrate metabolism. P. J. CAMMIDGE. *Brit. Med. J.* 1925, II, 1216-8.—Rats fed raw fresh pancreas showed no fall in blood sugar, and unchanged respiratory quotient in 5 to 6 animals (that in the 6th was doubtful). No effects were obtained with a no. of com. pancreas preps. fed by mouth.

A. T. CAMERON

Action of pituitary extract administered by the alimentary canal. H. H. KNAUS. *Brit. Med. J.* 1926, I, 234-5.—No pressor effect was observed in the cat when the ext. was given by mouth, stomach, small intestine or rectum. No influence on uterine muscle was found when the ext. was given by stomach or small intestine, but given by mouth, after a latent period of 8 min. there was marked influence on the uterus increased tone and automatic movements. The oxytocic compd. is, therefore, absorbed by mouth; there was also slight absorption by rectum.

A. T. CAMERON

A comparative study of the effect of two different preparations of iodine upon the preoperative basal metabolic rate in exophthalmic goiter. R. R. FITZGERALD. *Can. Med. Assoc. J.* 16, 159-61 (1926).—Lugol's soln. was compared with I in HI. Lowering of the basal metabolic rate was effected in nearly all cases, with either soln., each producing the same diminution in about the same length of time, but nearly 4 times the amt. of I in HI was necessary for the same clinical effect as with Lugol's soln.

A. T. CAMERON

The use of insulin in surgery and obstetrics. F. N. G. STARR AND A. G. FLETCHER. *Surgery, Gynecol., Obstetrics* 42, 194-5 (1926).—A clinical paper indicating the value of insulin and intravenous glucose in surgery and pregnancy with diabetics.

A. T. C.

Anatomic alterations in experimental poisoning by cocaine with special reference to the glands of internal secretion. G. FALCO. *Arch. farm. sper.* 40, 164-219 (1925).—Acute exptl. poisoning by cocaine produces, in the dog, guinea pig and rabbit, lesions in the organs concerned in 3 fundamental functions: those of the central nervous system already studied by other investigators, those of the vital organs (kidney, liver and heart) and those of the testes. The last are characterized by a diminished spermatogenic activity with increase in interstitial tissue. The mode of action in this case is probably similar to that of EtOH.

A. W. DOX

Histological investigations on some organs of rabbits after death from acute and subacute poisoning by disodium methylarsenate (arrenal). P. TESTONI AND STEFANO CASTAGNA. *Arch. farm. sper.* 40, 257-68 (1925).—Degenerative changes were noted, particularly in the liver, kidney and intestine, after subcutaneous injection of the drug. In acute poisoning the lesions were exclusively hemorrhagic.

A. W. DOX

Anatomo-pathological investigations on some organs of rabbits after death from acute and subacute poisoning from sodium cacodylate. P. TESTONI AND P. BISSIRI. *Arch. farm. sper.* 40, 269-82 (1925).—Degenerative and hemorrhagic lesions were observed in the kidney, liver, intestine and suprarenals, and mainly hemorrhagic lesions in the lungs, bone marrow and spleen. More damage was done by subcutaneous than by intravenous injection, probably because of less opportunity for elimination by the lungs.

A. W. DOX

Therapeutic use of caustic soda. GEORGES DENIGÈS. *Bull. soc. pharm. Bordeaux* 63, 313-4 (1925).—D. employed a 4% soln. of NaOH, administered by stomach tube, in the treatment of gastric ulcer. Contrary to what would be expected, this strongly caustic soln. does not produce vomiting or hemorrhage, except in rare cases.

A. G. DU MEZ

Bryonia alba: a typical animal proving. T. G. MITCHELL. *J. Am. Inst. Homeopathy* 19, 105-6 (1926).—Administration of alc.-free tincture of bryonia to guinea pigs for a period of several weeks, either by mouth or hypodermically, produced loss of body wt., congestion of the brain, cervical glands, lungs, pleura and synovial membranes, anemic kidneys and blood in the contents of the stomach, cecum and urinary bladder.

JOSEPH S. HEPBURN

Arnica montana. H. S. STIMPSON. *J. Am. Inst. Homeopathy* 19, 213-5 (1926).—Guinea pigs were killed by administration of lethal doses of arnica; they were subjected to autopsy immediately after death, and then exhibited a tendency to hemorrhage, disintegration of the intestinal mucosa and cloudy swelling. Administered to anesthetized rabbits, arnica increased the respiratory rate and the rate of beating of the left ventricle, and decreased the blood pressure and the tonus of the cardiac muscle.

Applied to the isolated intestine in Tyrode soln., arnica produced a cessation of contraction, and first an increase, then a decrease in tonus; this action was not antitided by camphor. In the Langendorff perfusion method, arnica produced a definite slowing of the heart.

JOSEPH S. HEPBURN

Effects of ultra-violet radiation upon involuntary muscle, and the supposed physiological interference of visible rays. Y. AZUMA AND LEONARD HILL. *Proc. Roy. Soc. (London)* 99B, 221-9(1926).—Ultra-violet rays antagonize the action of adrenaline, but not that of emetine, upon involuntary muscle. The increased tone, produced by these rays, is dependent upon the presence of Ca in the nutrient fluid.

J. S. H.

The action of secretin from nettles on the secretion of bile. M. DOBREFF. *Z. ges. expil. Med.* 46, 243-62(1925).—Secretin isolated from the leaves of the nettle, *Urtica dioica*, is an active cholagog and increases the secretion not only of H₂O but also of solid constituents. Young leaves give a more effective secretin than old leaves. The strength of the secretin does not alter on standing. Another nettle, *Urtica urens*, gives a secretin which is less powerful as a cholagog, resembling in its action the secretin from spinach. It is probable that the same substance in plant secretins is responsible for the increased secretion of both stomach and liver.

H. F. H.

The influence of vagotropic substances on the concentration of hydrogen and hydroxyl ions in the saliva in man. J. LUKOMSKY AND M. GURARY. *Z. ges. expil. Med.* 47, 285-93(1925).—The H-ion concn. of the saliva is decreased by subcutaneous injection of pilocarpine and increased by subcutaneous injection of atropine.

HARRIET F. HOLMES

The behavior of intravenously introduced bismuth in the body and its excretion. A. MEMMESHEIMER. *Z. ges. expil. Med.* 47, 151-65(1925).—The intravenous injection of an adsorption combination of Bi with As, known as Salluen, brings about a marked shock to the stability of the colloids of the blood as shown by changes in refractive index, viscosity and surface tension. Bi is demonstrable in the blood chiefly in a dialyzable form in the serum and in a non-dialyzable form in the plasma. Small quantities of Bi are found in the liquor cerebri in man. The colloidal combination splits off Bi slowly and the Bi is taken up to a considerable extent by the reticulo-endothelial system. Excretion of Bi through the kidneys and intestine is slow, so there is a long-continued action of the Bi.

HARRIET F. HOLMES

Influence of radiotherapy on uric acid excretion. SEBASTIANO DI FRANCESCO. *Actinoterapia* 4, 193-20(1924); *Ber. ges. Physiol. expil. Pharmacol.* 29, 410. —No increase of uric acid was found in urines during or immediately after Ra or Röntgen irradiation. In 24-hr. urines examd. on several consecutive days an increase was found in 3 cases of carcinoma and 2 of myoma. It is attributed to the destruction of tumor cell nuclei.

MARY JACOBSEN

The effect of histamine on cerebrospinal fluid pressure. F. C. LEE. *Am. J. Physiol.* 74, 317-25(1925). A definite fall in cerebrospinal fluid pressure was produced by 0.02-2 mg./kg. histamine, with a slight rise after the min. It was closely paralleled by the arterial pressure which after the min. rose above its original value. The venous pressure curve presented the mirror image of the arterial pressure curve. While the blood capillaries of the viscera are markedly dilated in histamine shock the blood capillaries of the brain do not dilate, as was confirmed by direct observation and histological examn.

MARY JACOBSEN

A note on differences of capillary activity. F. C. LEE. *Am. J. Physiol.* 74, 326-33(1925); cf. preceding abstr. —Histamine and 30% NaCl lowered arterial and cerebrospinal fluid pressure while lymph flow and pressure were increased. These as well as previous expts. establish a fundamental difference in behavior between the capillaries of various organs. The passage of particles of India ink from lymph vessels to the liver indicate a high degree of permeability of the blood vessels of the liver.

MARY JACOBSEN

The regulation of the flow of bile. G. E. BURGET. *Am. J. Physiol.* 74, 583-9(1925).—The pressure in the bile duct is increased by pilocarpine and physostigmine and reduced to a min. by adrenaline and atropine. Since these drugs act on the tonus of the intestinal musculature it is concluded that the flow of bile is regulated mainly by intraabdominal pressure and by tonicity and peristalsis of the duodenum.

M. J.

Studies of response to continuous intravenous injection of large amounts of glucose. J. D. BOYD, H. M. HINES AND C. E. LEESE. *Am. J. Physiol.* 74, 656-73(1925).—Dogs received injections of glucose extending over 2-4 hrs. at a rate of 4 g./kg. per hr. The injection was assoc. with a rapid rise of blood sugar in the first few mins. tending to assume a plateau, a 50% increase in heat production, slight rise in body temp. and a slight decline in plasma p_H and CO₂ content, the latter being independent of the p_H

of the injected soln. The degree of hyperglucemia is not an index of the assocd. glucosuria. About 20% of the injected glucose is excreted. The respiratory quotient indicates predominant sugar combustion but there is no positive evidence of fat formation. After the injection is completed blood sugar and heat production rapidly return to normal. Qualitatively the effects are similar in different dogs, but quantitatively they differ considerably. MARY JACOBSEN

The effect of insulin on the morphological blood picture, with a note on the relation of diet to the convulsions induced by insulin. V. E. LEVINE AND J. KOLARS. *Am. J. Physiol.* **74**, 695-707(1925); cf. *C. A.* **19**, 3315.—Rabbits fed on alfalfa (base-producing) invariably fell into convulsions; those fed on oats and cabbage (acid-producing) did not. These and the results of other authors suggest that insulin convulsions are due not to hypoglucemia but to a state of inadequate nutrition resulting in nervous instability. The latter becomes manifest under the action of insulin. MARY JACOBSEN

The influence of alcohol. I, II. H. L. HOLLINGWORTH. *J. Abnorm. Psychol. Soc. Psychol.* **18**, 204-37(1924); *Ber. ges. Physiol. expll. Pharmacol.* **29**, 448.

Therapy of infantile leishmaniasis. S. CANNATA. *Pediatrics (Riv.)* **33**, 1309-11(1925).—Na Sb tartrate is an anti-*Leishmania* specific and effects relatively rapid improvement and recovery even in cases resistant to Sb tartrate. The tolerance even for high doses is good. MARY JACOBSEN

Excretion of mercurochrome given intravenously. R. L. COWEN. *Am. Med.* **31**, 732-4(1925).—The excretion of the dye from the normal kidney starts within 3 min after intravenous administration. It is excreted as rapidly by the diseased kidney; hence it is not an index of renal function. Thirty % or more is excreted within 24 hrs. In one case the dye was seen in aural secretions. None was noticed in the spinal fluid. Excessive doses are followed by excretion into the lacrimal and intestinal secretions. None is excreted into the seminal vesicles; hence it has no therapeutic value. F. K.

Treatment of frambesia with novasurol. W. FISCHER. *Arch. Schiffs-Tropen Hyg.* **29**, 339-42(1925).—F. reports great success in curing frambesia by the injection of novasurol. FRANCES KRASNOW

Behavior of "yatren" in the organism. ADOLF KESSLER. *Arch. Schiffs-Tropen Hyg.* **29**, 380-7(1925).—"Yatren" cannot be administered by inunction. I is split off in the organism. The elimination of I and "yatren" in the urine is greater after intravenous or intramuscular injection. When "yatren" is administered *per os* there is a delay and decrease in the amt. excreted by the urine. FRANCES KRASNOW

A case of ulcer tropicum cured with neoarsphenamine and cupric sulfate solution. A. TERDSCHANIAN. *Arch. Schiffs-Tropen Hyg.* **29**, 449-50(1925).—Report. F. K.

Mechanism concerning the therapeutic action of bismuth in syphilis after intravenous injection. S. SEI AND W. WEISE. *Arch. Schiffs-Tropen Hyg.* **29**, 554-9(1925). The Bi soln. is rapidly distributed to all organs and hence also to the syphilitic tissues. Much is lost through the kidneys. Small doses act more effectively. F. K.

Chemotherapeutic studies on antimony. PAUL UHLENHUTH, PHILALETHES KUHN AND HANS SCHMIDT. *Arch. Schiffs-Tropen Hyg.* **29**, 623-50(1925).—Aromatic Sb compds. are classified and their action on trypanosomes is discussed. F. K.

Pulmonary hemorrhage after acute carbon tetrachloride poisoning. T. TAKASAKA. *Deut. Z. ges. ger. Med.* **6**, 488-99(1925).—In cases of acute CCl_4 poisoning there is always pulmonary hemorrhage. The greater the dose the more severe is the bleeding and the more hasty is death onset. The blood is hemolyzed. No rupture of vessels is observed. In addn. there appears often a fatty degeneration of liver, kidney and heart. F. K.

Chemotherapy of antimonial compounds in kala-azar infections. XVIII. Further observations on certain derivatives of *p*-aminophenylstibinic acid continued. U. N. BRAHMACHARI AND JUDHISTHIR DAS. *Indian J. Med. Research* **13**, 693-4(1926). cf. *C. A.* **20**, 591.—Condensation of acetamide with *p*-aminophenylstibinic acid: To 4 g. of *p*-aminophenylstibinic acid, treated with an aq. soln. of NaOH until dissolved and made alk. with a slight excess, is added 1 g. dichloroacetamide. The mixt. is heated at 60-70°, the soln. kept alk. by small addns. of NaOH, filtered and the filtrate cooled on ice. Dil. HCl is added in excess, the ppt. thus formed washed 2 times in dil. HCl and 5 times in water and dissolved in NaOH. The soln. is made neutral, filtered and concd. Abs. alc. gives a ppt. which is dried over CaCl_2 . FRANCES KRASNOW

Critical tests of tetrachloroethylene, new anthelmintic, with special reference to its use in puppies. A. S. SCHLINGMAN. *J. Am. Vet. Med. Assoc.* **68**, 225-31(1925).—"Tests on 31 puppies and dogs indicate that C_2Cl_4 is as effective as CCl_4 for the removal of hookworms, the drug removing all of these worms present..... The effectiveness of C_2Cl_4 against whipworm was variable..... No effect on tapeworms was noted. The

safety of C_2Cl_4 for puppies is higher than CCl_4" Trial in cases of human hookworm diseases is recommended.

Neosarsphenamine in the treatment of amebic dysentery. P. T. LANTIN. *J. Philippine Islands Med. Assoc.* 5, 269-75(1925).—Eleven cases were treated. Neosarsphenamine "shows signs of considerable therapeutic value against chronic amebic dysentery."

FRANCES KRASNOW

A summary of recent developments in the chemistry of leprosy therapy. G. A. PERKINS. *J. Philippine Islands Med. Assoc.* 5, 369-73(1925).—Chemotherapy in leprosy depends on the chaulmoogra group of oils and fixed vegetable and animal oils not in the chaulmoogra group. The distinguishing characteristic of the former is that they contain a large % of chaulmoogric acid. The therapy may be administered orally using the oil-bearing seeds or subcutaneously using pure oil. Ethyl esters of chaulmoogric acid are more active than the oil. The Na salt of the acid is still more active and may be used intravenously. Of the oils not in the chaulmoogra group, cod-liver oil is the most important. Soy-bean oil has been reported as favorable. It is believed that the effects produced by these oils, when administered intramuscularly or subcutaneously, are due to their unsatn. Ingestion has no apparent effect. In this respect the latter 2 oils differ from the oils of the chaulmoogra group. These act, although to a lesser extent, when ingested. Olive oil has practically no effect. F. K.

The effect on leprosy of certain oils not in the chaulmoogra group. BONIFACIO DE VERA. *J. Philippine Islands Med. Assoc.* 5, 374-8(1925).—Four groups of oils are considered, depending on the degree of unsatn.: highly unsatd. oils as cod-liver oil; moderately unsatd. oils as soy-bean oil and its esters; slightly unsatd. ones as olive oil and its esters; and practically satd. ones as coconut oil and its esters, ethyl stearate and ethyl margarate. In general, the greater the unsatn. the greater the curative value.

FRANCES KRASNOW

Phosphorus in the treatment of various diseases. ALDO CASTELLANI. *J. Trop. Med.* 28, 377(1925).—Discussion.

FRANCES KRASNOW

A note on the treatment of amebic dysentery with stovarsol. F. M. JOHNS AND CHAILLE JAMISON. *J. Trop. Med.* 28, 378-9(1925).—Stovarsol gives results which compare favorably with other means for the treatment of amebic dysentery. F. K.

Bilharzia treatment. Experience gained from more than 3000 tartar emetic injections. Precautionary measures. Results obtained. P. H. J. LAMPE. *J. Trop. Med.* 29, 4-10(1926).—"The tartar emetic injection, when applied with the necessary discernment and tactfulness, will in the long run enjoy the popularity indispensable in combating the diseases, bilharziasis and filariasis."

FRANCES KRASNOW

A cured case of quinine idiosyncrasy. F. HAPKE. *Arch. Schiffs-Tropen Hyg.* 29, 343-4(1925).—Report.

FRANCES KRASNOW

The action of sodium and calcium ions on the frog heart and their influence on the heart tone. ERNST HOLZLÖHNER. *Z. Biol.* 83, 107-19(1925).—The work of Sakai is confirmed. By means of lowering the NaCl in a bathing soln. the sp. action of Na ions becomes recognizable. The action of the inorg. ions is detd. by the ratio: $(\text{K}-\text{Na})/\text{Ca}$. The optimum value of this ratio varies for the upper and lower heart. The effect of a decrease in NaCl is not dependent on the hypothetical disson. of dextrose. Contrasting effects between 6% and 1% NaCl is independent of the p_H of the 2 solns. A rise in the contraction accompanies a decrease in Na. This is also a sp. action of Ca increase uncompensated by increase in K or Na.

FRANCES KRASNOW

Hypertensive hyperglucemia. G. FRITZ AND B. PAUL. *Biochem. Z.* 157, 263-70(1925).—Hypertension produced in cats and rabbits by means of strychnine preceded by curare, BaCl_2 and strophanthin is compared by measurement of blood pressure and sugar, with hypertension produced by compression of the aorta. W. D. L.

Influence of the ions calcium, potassium and magnesium upon the mechanism of secretion by the gastric glands. Y. MUKOYAMA. *Biochem. Z.* 157, 303-32(1925).—After intravenous injection of salts, such as CaCl_2 , MgCl_2 or KCl into dogs with Pavlov blind sacs, the gastric secretions into the sacs were collected. While MgCl_2 and KCl stimulated, CaCl_2 depressed the flow of gastric juice. W. D. L.

The diuretic action of chlorophyll. T. GORDONOFF AND T. AMAKAWA. *Biochem. Z.* 157, 333-8(1925).—After the intravenous or peroral application of Na chlorophyllin to rabbits, the urine excretion increased to a max. in 2 hrs. The increase was not uniform, and in many cases was not great. The chlorophyll was largely excreted in the urine, which became green in color. W. D. L.

Influence of insulin upon the sugar exchange of the isolated rat's liver. I. F. BERNHARD. *Biochem. Z.* 157, 396-413(1925).—To det. whether or not insulin has an effect upon the sugar metabolism of the isolated warm-blooded liver, rat's liver was

perfused with Ringer or Tyrode soln., with and without the addn. of glucose and of insulin to the perfusate. Reducing sugar was detd. every 0.5 hr. Glycogen was detd. at the beginning and at the end of the expt. With sugar present in the perfusate, a sugar deficit was found, which deficit increased as the sugar present increased. A synthesis of glycogen could not be demonstrated, but with increasing amts. of glucose, the hydrolysis of glycogen was repressed. The addn. of insulin doubled the amt of glucose which disappeared. The concn. of sugar in the liver was directly proportional to the concn. of sugar in the perfusate. W. D. L.

The extra-hepatogenous bile pigment formation in surviving organs. IV. The surviving spleen of dogs treated with collargol and with colloidal iron. Z. ERNST AND J. FÖRSTER. *Biochem. Z.* 157, 492-500(1925).—See C. A. 19, 1006. W. D. L.

The glycogen content of the liver. I. The behavior of blood sugar and liver glycogen under the influence of morphine. N. FRANK AND J. FÖRSTER. *Biochem. Z.* 159, 48-52(1925).—The hyperglucemia, and the decrease of liver glycogen in rabbits under the influence of morphine occur simultaneously, the max. change being noted in 2.5 hrs. These changes are, within limits, independent of the amt. of morphine used W. D. L.

Hormonal regulation of intermediary carbohydrate metabolism. II. Demonstration of the insulin-adrenaline antagonism in the living frog. A. GOTTSCHALK. *Biochem. Z.* 159, 502-6(1925); cf. C. A. 19, 3302.—Frogs with adrenaline injected show less marked insulin convulsions than similar frogs without adrenaline. Likewise, frogs in insulin convulsions may be relieved by injection of adrenaline. Therefore, insulin and adrenaline are antagonistic. W. D. L.

The problem of distribution. I. Organic lead compounds. R. EHRENBERG. *Biochem. Z.* 161, 337-8(1925).—The distribution of injected Et_3PbCl and Ph_3PbCl in the various organs of the body is not uniform. The lungs and kidney retain none, but the blood and brain retain a considerable amt. W. D. L.

Influence of the cations of Ringer solution upon the smooth musculature of guinea-pig uterus. M. KOCHMANN. *Biochem. Z.* 161, 390-400(1925).—Certain ions are omitted from Ringer solns. and replaced by others, so that the soln. is again isotonic with blood, and the effect of the modified soln. upon the uterus muscle observed. The effect of ions depends not alone on the ratio of K to Ca, but also upon the amt. of Na present W. D. L.

Adsorption of protein decomposition products by the form elements of guinea in vivo and in vitro. V. Influence of quinine upon the adsorption of diphtheria toxin by erythrocytes. B. SBARSKY AND L. SUBKOWA. *Biochem. Z.* 161, 406-15(1925). cf. C. A. 19, 3108.—Quinine *in vitro* is strongly bound by blood corpuscles and diminishes the power of the cells to adsorb protein hydrolytic products. By detg. the effect of injected quinine in prolonging the life of rabbits inoculated with diphtheria toxin, no such decreased adsorption of the toxin occurs. The difference is due to the fact that blood *in vivo* is in circulation. W. D. L.

Use of organic mercurials particularly mercurochrome. E. C. WHITE. *Am J. Pub. Health* 16, 153-5(1925). H. B. LEWIS

The effect of histamine on the blood chlorides. T. G. H. DRAKE AND F. F. TISDALL. *J. Biol. Chem.* 67, 91-100(1926).—Histamine has been suggested as the possible toxic agent in the intoxication of intestinal obstruction; a marked decrease in blood chloride has also been observed after the exptl. production of high intestinal or pyloric obstruction. Expts. performed to det. whether subcutaneous injection of histamine produces a reduction of the concn. of blood chlorides give evidence of a definite reduction which, however, bears no relation to the degree of intoxication. The reduction does not appear until the intoxication has been present for some hrs. and is not the result of a loss of Cl in the gastric secretion. A. P. LOTHROP

The antagonistic action of insulin and hypophyseal hormone on water content. I. SEREBRYSKI AND H. VOLLMER. *Biochem. Z.* 164, 1-8(1925); *Klin. Wochschr.* 4, 2256-7.—In expts. on urine secretion carried out according to Volhard's procedure both the pituitary hormone and insulin have an antidiuretic action. The combination of the 2 hormones, however, causes not a summation of their effects but a mutual inhibition so that pituitary and insulin together lead to a smaller water retention than pituitary alone. It is assumed that insulin inhibits centrally the blocking influence exerted by the pituitary on the kidney. S. MORGULIS

Quinine distribution in the organism of the dog. L. M. TCHAPKEWITCH. *Biochem. Z.* 164, 53-60(1925).—The essential feature of these expts. is the fact that by a special operative technic canulae were permanently inserted in the blood vessels leading to various internal organs and samples of blood could be painlessly collected at any time.

The quinine was detd. directly in the blood by the method of Giemsa and Schaumann. The liver and spleen were found to retain the largest amt. of quinine. Quinine leaves the organism in an unchanged state through the kidneys (30%) and this excretion commences a few min. after parenteral administration.

S. MORGULIS

The curve of the disappearance of bilirubin injected intravenously into dogs. J. P. BOUCKAERT AND R. APPELMANS. *Compt. rend. soc. biol.* 93, 843-5(1925).—Fifteen mg. of bilirubin injected intravenously into dogs causes a sudden rise of the bilirubin of the serum which disappears after 1-2 hrs. Following, however, mild P poisoning for several days, or ligation of the bile duct, the excretion of the bilirubin seems to be blocked.

S. MORGULIS

Studies of partial bromination of phlorhizin. III. KEIZO MISAKI. *J. Biochem.* (Japan) 5, 287-91(1925); cf. *C. A.* 20, 422.—The glucosuric effect of phlorhizin is greatly reduced by bromination. 0.2-1 g. of dibromophlorhizin in 5% Na_2CO_3 or in suspension in olive oil was injected into rabbits or dogs, the urine being collected after 6 hrs. by catheterization. The blood sugar was also studied. The expts. show that the blood sugar level remains unaffected by the administration of the dibromophlorhizin.

S. MORGULIS

A study of animal tissue respiration and the effects of insulin, adrenaline, thyroxin and hypophyseal preparations. GUNNAR AHLGREN. *Skand. Arch. Physiol.* 47, Supplement, 266 pp.(1925); cf. *C. A.* 19, 1901.—This extensive monograph is prefaced by a detailed description of the methylene blue method for the study of tissue respiration, and a general discussion of the various factors. From the study of the effect of insulin on tissue respiration it is concluded the utilization of glucose without the intermediate step of lactic acid depends upon the intactness of a triple system consisting of insulin + $\alpha\beta$ -glucose + glycomutin. The absence of insulin, as in pancreas diabetic condition, leads to acidosis; absence of glucose results from insulin intoxication; inactivation of the glycomutin occurs in phlorhizin poisoning where acidosis appears in spite of the presence of glucose and of insulin. The $\alpha\beta$ -glucose is not a direct H-donor, and for oxidative processes in the organism it is attacked either by preliminary splitting to lactic acid (without the aid of insulin) or through conversion to a highly reactive α -glucose under the combined influence of insulin and glycomutin. Glycogen and other polymers of glucose, fructose and galactose can be oxidized in the tissues without passing through the lactic acid intermediate stage and without the aid of insulin. Adrenaline like insulin also increases the rate of tissue oxidation. But the 2 hormones act as physiol. antagonists, probably because they affect differently the glucose transformation by glycomutin, thus: Insulin accelerates the change $\alpha\beta$ -glucose \rightarrow α -glucose, while adrenaline accelerates the change α -glucose \rightarrow $\alpha\beta$ -glucose. The exact nature of this chem. change is, of course, not understood, as is also the considerable stimulation of tissue oxidation by a small concn. of adrenaline. Thyroxin influences the respiration of muscle from thyroidectomized animals to the extent of increasing this to the level of normal muscle tissue. The smallest effective doses of the 3 hormones were as follows: for insulin, approx. 10^{-16} ; for adrenaline, 10^{-15} and for thyroxin 10^{-17} - 10^{-18} . Pituitrin, like thyrosin, also stimulates tissue oxidation. Unlike thyroxin, however, it loses its effect completely when the tissue has been preserved aseptically at room temp. for 2 hrs. In this respect pituitrin behaves like insulin; unlike insulin, its effect does not depend upon the presence of $\alpha\beta$ -glucose. Pituitrin concns. of 10^{-8} - 10^{-9} produce a rise of 25-30% in tissue respiration; at concns 10^{-4} - 10^{-5} inhibition instead of acceleration takes place; while the min. effective concn. is 10^{-11} - 10^{-12} . The study of the combined effect of 2 hormones gives the following result: insulin and adrenaline, insulin and thyroxin, adrenaline and thyroxin, adrenaline and pituitrin are invariably antagonistic to each other; insulin and pituitrin are synergic; while the combination of thyroxin with pituitrin produces sometimes antagonistic and sometimes synergic effects.

S. MORGULIS

Lethal poisoning by barium carbonate. DUFOUR. *Ann. méd. légale* 1, 29-33 (1921).—D. describes in detail the results of an autopsy performed after BaCO_3 poisoning, of interest on account of the rarity of such occurrences.

A. P.-C.

Elimination of alcohol from the organism of dogs accustomed to ingestion of alcohol. BALTHAZARD AND LARUE. *Ann. méd. légale* 1, 291-2(1921).—Contrary to Pringsheim (*C. A.* 3, 917) B. and L. found that in a dog which had been accustomed to take alc. its elimination took place in the same manner and required the same length of time as in a dog which had not been so accustomed.

A. PAPINEAU-COUTURE

Action of experimental alcoholism on testicles: histological and chemical study. ALEXANDRE KROSTITCH. *Thesis*, Strasbourg, 1921; *Ann. méd. légale* 2, 196(1922).—Chem. investigation showed that the testicle fixes more EtOH than the other important

organs. K.'s histological investigation shows that the seminal epithelium is particularly sensitive to the action of EtOH, which destroys the seminal cells in inverse order of their generation, the spermatogonia being the last to remain. The persistency of the generative layer renders possible the regeneration of the epithelium; but the seminal cells may suffer from alc. degeneracy, which may account for hereditary blemishes in the children of alcoholics. The interstitial gland resists alc. intoxication better than the seminal epithelium. Alcoholism can thus induce sterility without incapacity.

A. PAPINEAU-COUTURE

The localization of arsenic in acute experimental intoxication. A. LOPÈS D'AN DRADE. *Ann. méd. légale* 2, 229-30(1922).—The bulb and cerebellum retain the largest proportion of As and then, in decreasing order, the brain, the kidneys, the liver and the digestive organs (stomach and intestines). No appreciable difference was found when the poison was administered *per os*, hypodermically or intravenously. A. P.-C.

Elimination and fixation of therapeutic neoarsphenamine. E. KOHN-ARREST AND J. A. SICARD. *Ann. méd. légale* 2, 70-91(1922).—Examn. in 1911-18 of the viscera of 116 corpses taken at random from those which were sent to the morgue, but excluding those where death might have been due to As poisoning, showed: 99 contained not over 0.3 mg., 13 contained 0.3-0.8 mg., 3 contained 1-2 mg. and 1 contained 2.4 mg. As, in the whole of the viscera. Results are given of the examn. of the viscera of a no. of patients who had been given neoarsphenamine treatment, the exact history of which in each case was known, of the examn. of cerebrospinal fluid of patients undergoing treatment, and of the examn. of the viscera of rabbits after subjecting them to the treatment. *Conclusions:* (1) elimination of neoarsphenamine injected intravenously is very rapid, as much so as that of other arsphenamine preps., but when injected subcutaneously it is only about half as rapid; (2) the following organs contain As in increasing order of magnitude, lungs, intestines, spleen, kidneys, liver; the brain contg. practically none (not over 0.0002 g.) after intense intravenous treatment and somewhat more (0.0002-0.00075) after subcutaneous treatment; (3) presence of several mg. of As in the brain is an indication of As intoxication. In the interpretation of toxicological analysis, presence of up to 1 mg. of As in the whole of the viscera is of no importance; presence of 1-3 mg. would indicate a therapeutic As treatment; presence of 3-7 mg., with due regard to its distribution, may be merely an indication of a neoarsphenamine treatment dating back 2-25 days, the As being in the course of natural elimination; presence of 0.1 g. or more indicates poisoning. A. PAPINEAU-COUTURE

Clinical experimenting with intarvin. STERN. *Med. Klin.* 21, No. 26(1925). *Bull. soc. hyg. aliment.* 13, 524(1925).—Clinical tests on 5 diabetic patients did not prevent aggravation of the disease: in every case there was an increase in the acetone compds. in the blood. Intarvin was found to be disagreeable to the taste, and some of the patients could not tolerate it. A. PAPINEAU-COUTURE

Action of the base tropine (tropanol) on the circulation. RENÉ HAZARD AND L. J. MERCIER. *Compt. rend.* 181, 934-6(1925).—Tropine injected intravenously into the dog in doses of 0.01 to 0.05 g. per kg. produces a marked lowering of the blood pressure, a const. slowing of the cardiac rhythm and an increased amplitude of the cardiac pulsations. L. W. RIGGS

Double hyposulfite of gold and sodium in the treatment of syphilis. L. FOUYNIER AND P. MOLLARET. *Compt. rend.* 181, 943-5(1925).—Au Na hyposulfite has a strong antisyphilitic action when given in frequent doses of about 1 g. Its administration is followed by a disappearance of treponemes, the rapid cicatrization of sp. lesions and an attenuation or even disappearance of the Bordet-Wassermann reaction. In doses of 0.5 g. or less its action is slower and sometimes doubtful. L. W. RIGGS

Action of yohimbine and of the active alkaloids of ergot on the vaso-motor sympathetic innervation of the kidney. RAYMOND-HAMET. *Compt. rend.* 182, 170-3(1926).—Apart from yohimbine the active alkaloids of ergot (ergotamine, ergotoxine, ergotinine) are alone in different degrees, able to cause the paralysis of the renal vaso-constrictor and this action is proposed as a physiol. measure of the activity of the exts. of ergot. L. W. RIGGS

Effect of nicotine upon the adrenaline output from the suprarenal glands. TADASHI SUGAWARA. *Tôhoku J. Exptl. Med.* 6, 430-58(1925).—Cats were used in all the expts. Nicotine, intravenously injected in doses of 0.025 to 0.5 mg. per kg., caused a briefly continued increase of the adrenaline output. This increase, which continued not longer than 2 min., was followed by a depressant stage which lasted many min. At the time of max. depression no adrenaline could be detected in some cases. The effect of nicotine subcutaneously administered in doses of 0.4 to 1.0 mg. per kg. is of the same nature but inferior and the duration of the accelerating stage is somewhat longer. The ad-

renaline output of the cats, the splanchnic nerves of which were then or previously divided, showed the same tendency toward nicotine. Nicotine acts on the supranrenal medulla itself.

L. W. RIGGS

Gas metabolism and minute volume. II. Vegetative nervous system. TSUROMU ODAIRA. *Tôhoku J. Exptl. Med.* 6, 523-33(1925); cf. C. A. 20, 241.—Rabbits were used in all these expts. Intravenous injection of 0.2 to 0.55 mg. per kg. atropine sulfate was followed by no change in O consumption, but the minute volume (m. v.) was quite strongly increased. From 1.0 to 2.0 mg. pilocarpine per kg. given intravenously reduces the gas exchange and to a much greater degree the m. v. Thus the diminution of the gas exchange by pilocarpine is secondary to the lowering of the blood circulation. The action of pilocarpine upon gas exchange and m. v. is completely neutralized by atropine. Intravenous injection of choline in doses of 2-5 mg. per kg. reduces the gas exchange alone, but doses of 10 mg. per kg. reduced both gas exchange and m. v. Atropine neutralizes the action of choline. **III. Gas metabolism and minute volume during heat-puncture hyperthermia; and the influence of antipyretics, inner secretions and vegetative nerve poisons on both.** *Ibid* 534-65.—Heat-puncture hyperthermia is accompanied by an increase of gas metabolism and m. v. The administration of quinine to rabbits previously subjected to heat-puncture caused a lowering of body temp., gas metabolism and m. v.; atropine caused a similar but less pronounced lowering. Na salicylate caused a fall in body temp. but acted only slightly on the other factors. Adrenaline in doses of 0.025 to 0.5 mg. per kg. caused a pronounced decrease in gas metabolism and m. v. Atropine, which had no effect on the gas exchange of the normal rabbit, caused an increase in the gas exchange and m. v. in the heat-punctured animal. Pilocarpine and choline lower the gas exchange, body temp. and m. v. of heat-punctured rabbits. Pituitrin lowered the temp. and gas exchange more in heat-punctured than in normal rabbits. On the contrary the m. v. is less changed than with normal animals. Insulin lowered the temp. of heat-punctured rabbits, but had less effect on the gas exchange and m. v. than was the case with normal animals.

L. W. RIGGS

Non-volatile aliphatic compounds in general anesthesia. R. K. LAMBERT. *Lancet* 1925, I, 121-3.—Non-volatile aliphatic compds. in general and more particularly a mixt. of isopral and hedonal are recommended as anesthetics. The completion of anesthesia by gases may be facilitated and the duration of their use reduced by a preliminary use of these anesthetics.

F. B. SEIBERT

The therapeutic properties of stovarsol (acetylaminophenylarsinic acid "190"). C. LEVADITI. *Lancet* 1925, II, 593-5.—Administration by mouth proved successful in syphilis, yaws, spirillary infections in general, ameboid dysentery, intestinal lamblia-sis, blastocystic diarrheas and malaria.

F. B. SEIBERT

The efficacy of tryparsamide in the cure of African sleeping sickness. C. C. CHESTERMAN. *Lancet* 1925, II, 965-7.

F. B. S.

Experimental and clinical investigations of mercurochrome. A. T. TODD. *Lancet* 1925, II, 1017-19.—Mercurochrome is a powerful antiseptic of low toxicity, rapid and deep penetrability and causes little irritation. It does not ppt. albumins and is stable for long periods in normal NaCl soln. Its antiseptic properties are augmented by acidity and are diminished by increased density of solvent and are, therefore, relatively feeble and unlikely to be of value in general infections where acidities are near to normality.

F. B. SEIBERT

Novasurol: a new diuretic. A. R. GILCHRIST. *Lancet* 1925, II, 1019-21.—It is a diuretic of great value in cardiac failure.

F. B. S.

Margosa oil in the treatment of cancer. K. K. CHATTERJI. *Lancet* 1925, II, 1063-5.—The ethyl ester of margosic acid and Cu margosate with or without irradiation are recommended in the treatment of cancer.

F. B. S.

Borocaine: a new local anesthetic. E. WATSON-WILLIAMS. *Lancet* 1926, I, 16-7.—Exptl. methods of estg. toxicity and efficiency showed 3 drugs to be in the proportion—cocaine-HCl, 1; novocaine, 0.15; borocaine E, 0.09. The efficiency of the drugs as measured by the production of deep anesthesia in the nose, after application to the mucous surface, is in the proportion—cocaine-HCl, 1; novocaine, 0.11; borocaine, 0.09.

F. B. SEIBERT

Methemoglobin restitution. III. Experiments in the living animal. KYUICHI SAKURAI. *Arch. exptl. Path. Pharm.* 109, 214-32(1925); cf. C. A. 20, 442.—In fatal aniline intoxication of cats the administration of thiosulfate has a favorable influence upon the symptoms accompanying the disturbance, and the formation of methemoglobin is reduced. Nevertheless the treated animals die, probably because of an effect on the central nervous system. In nitrite intoxication of cats the intravenous injection of thiosulfate has an unquestioned favorable effect on the non-narcotized animal.

The number of animals which survive a lethal dose are greatly increased. In narcotized animals thiosulfate injected intravenously markedly reduces the percentage of methemoglobin in the blood. With large doses of nitrite (0.035 g. per kg.) thiosulfate therapy is of no value. In rabbits no comparable therapeutic effects can be observed.

G. H. S.

Action of strontium ions on the heart in cold-blooded and warm-blooded animals. S. HIRSCH AND ALB. OPPENHEIMER. *Arch. expl. Path. Pharm.* **110**, 89-102(1925).—The frog heart arrested by NaCl soln. regains its activity by substituting a Sr-contg. soln. Ringer soln., in which the Ca is replaced by equimol. amts. of Sr, is less effective than is a normal Ringer soln., or a K-free Sr soln. The diminished effectiveness of Sr under these conditions, as compared with Ca, is in part due to the fact that Sr exerts a weaker antagonistic effect toward the paralyzing action of K than does Ca. Doubling the Sr content of the soln. renders it more effective. As regards the duration of activity of the frog heart no Sr combination is equiv. to normal Ringer soln. Continued perfusion of the rabbit heart with a Sr soln., in which Sr is substituted for Ca, causes a reduction in amplitude, a lengthening of systole, a shortening of diastole, a marked retardation of pulsation and often arrhythmia. Prolonged perfusion with K-free Sr-Locke soln. leads to the same changes, but they are abolished by injections of Ca. The reduction of frequency caused by Sr is apparently due to the action of the Sr on the heart muscle itself. When Ca or Sr is introduced directly into the canula through which normal Locke soln. is flowing it appears that about 2 times as high a concn. of Sr as of Ca must be injected to obtain the same systolic effect upon the normally beating heart. Continued perfusion with a Locke soln. contg. Sr causes a marked contraction. Expts. on both the frog and the rabbit heart clearly indicate the Sr is in no way superior if it is equal, to Ca in the effects produced.

G. H. S.

Effect of choline and some choline esters on the blood pressure after extirpation of the adrenals. S. GLAUBACH AND E. P. PICK. *Arch. expl. Path. Pharm.* **110**, 212-24 (1925).—Cholazyl (a chloroacetylcholine chloride-urea compd.) induces a fall in blood pressure in a concn. which is $1/10$ that of the choline necessary to exert a comparable effect. After treatment with atropine an increased blood pressure can be produced with $1/4$ to $1/6$ as much cholazyl as choline. In most instances where a bilateral adrenalectomy has been performed cholazyl fails to cause an increased blood pressure or if it occurs it is much weakened, while after a like surgical treatment choline as a rule causes the characteristic increased pressure. Even unilateral adrenalectomy reduces the pressor property of cholazyl. After adrenalectomy the amt. of cholazyl necessary to increase blood pressure is 4 times the normal effective dose, the effect resembling a nicotine-like stimulation of the sympathetics. A reaction of this type is not induced by choline nor by a normally active dose of cholazyl. In both normal and adrenalectomized animals ergotamine reverses the action of cholazyl as to its power to increase blood pressure; as is also the case with adrenalectomized animals which have undergone nicotine paralysis.

G. H. S.

Point of attack of insulin. E. FRANK, M. NOTHMANN AND A. WAGNER. *Arch. expl. Path. Pharm.* **110**, 225-40(1925).—In the animal with pancreatic diabetes, also under the influence of insulin, the tissues, particularly the muscle, withdraw increased amts. of sugar from the blood. This indicates a peripheral effect of insulin, rendering it highly probable that in the diabetic animal the sugar balance in the muscle is impaired.

G. H. S.

Analysis of the vascular effects of medicinal substances. I. G. GANTER. *Arch. expl. Path. Pharm.* **110**, 317-38(1926).—Detn. of the relative size of the vessels was made by detg. the rapidity of the fall in pressure in an arterial bed by compression for a few secs. of the chief artery leading in from the general circulation. The pressure due to closure of the vascular bed falls only to a fixed point if the test is made during the period of increased pressure consequent to adrenalectomy.

G. H. S.

Thoracic duct lymph of dogs. IV. Effect of oral administration of sugar and the intermediary water and ion movement. ROBERT MEYER-BISCH AND FRANZ GÜNTHER. *Arch. ges. Physiol.* (Pflüger's) **210**, 763-80(1925); cf. *C. A.* **19**, 3544.—The thoracic duct lymph and the blood were studied in dogs after the oral administration of dextrose and levulose. Changes in both blood and lymph occurred regularly, referable in large part to reduction in water, being revealed in the blood by an increase in hemoglobin, red cells and serum albumin, in the lymph by a reduced flow of lymph with a coincident increase in its content of protein, K and Ca. The Cl content of the lymph remained unchanged or slightly decreased. In the animals to which sugar had been given the infusion of hypertonic NaCl solns. altered the flow and compn. of the lymph in a manner entirely unlike its normal effect. The increased lymph flow, as well as the diln., is

lacking, despite the fact, as shown by the Cl values, that a very considerable hyperosmosis occurred. The factors increased by the sugar are restored to normal. In the blood, however, a diln. occurs just as in an untreated animal. Obviously the distinctive lymphagog action of intravenously administered hypertonic NaCl is prevented by the ingestion of sugar. G. H. S.

Relations between chemical constitution and irritation. E. G. PRINGSHEIM AND F. MAINX. *Naturwissenschaften* 13, 1090(1925).—It was previously found that the flagellate *Polytoma wella* occurring in decaying protein solns. lives on bacterially deaminized fatty acids. It was now found that many aromatic and aliphatic compds. (acids, alcs., oxyacids, aldehydes and ketones) also attract it by chemotaxis, even though they are in several cases undigestible. Maximal attraction was observed for compds. with 4 C atoms in every homolog series independent of ramification of the chain. Substitution of H by Cl influences the chemotaxis only slightly; OH instead of H causes it to decrease considerably. Polyvalent acids and alcs. are inactive (e. g., sugars). No relation between this phenomenon and the phys. properties (state of ionization, soly.) of the substances could be found. B. J. C. VAN DER HOEVEN

I—ZOOLOGY

R. A. GORTNER

Induction of melanism in the Lepidoptera and its subsequent inheritance. J. W. H. HARRISON AND F. C. GARRETT. *Proc. Roy. Soc. (London)* 99B, 241-63(1926).—Melanism may be induced (1) by introduction of non-melanic strains of insects from unaffected into melanic areas and feeding upon the local food plants, or (2) by feeding insects in non-melanic areas with food plants artificially charged with certain metallic compds. such as $Pb(NO_3)_2$ or $MnSO_4$. Melanism of the most pronounced type, which is thus induced, is then inherited as a simple Mendelian unit character. J. S. H.

New study on natural and cultural pearls. L. BOUTAN. *Ann. sc. nat. (Zool.)* 6, 1-91(1923); *Physiol. Abstracts* 10, 205-6.—Pearls are formed of an org. framework secreted by epithelial cells (ectodermal), permeated by a deposit of Ca carbonate secreted by migratory cells of mesodermal origin. There is no difference in the mode of formation, compn. or surface structure between natural and cultural pearls. H. G.

The action of ions present in sea-water on certain invertebrates. C. HEYMANS. *Arch. intern. pharmacodynamie* 29, 123-40(1924); *Physiol. Abstracts* 10, 143.—It is shown that in the medusa, *Pelagia noctiluca*, there is a balanced action of Ca, Mg, Na and K on the rhythmic pulsations and on the luminescence. Similar investigations on ion balance in other invertebrates are also described. H. G.

Adaptation of tadpoles to the chemico-physical conditions of their surroundings. A. CLEMENTI. *Atti accad. Lincei* 38, II, 427-30(1924); *Physiol. Abstracts* 10, 143.—Tadpoles die out if kept in hypertonic solns. of saccharose, while they survive in hypertonic solns. of urea or Ringer's fluid of the same mol. concn. In establishing the conditions under which tadpoles may live in solns. of crystalloids, besides the osmotic pressure, the chem. properties of the substances dissolved in the medium should also be taken into account. The present observations have an analogy with those of Overton on the neuro-muscular prepn., and of Baglioni on the isolated central nervous system of amphibia, the excitability of which disappears sooner in isoosmotic solns. of glucose or saccharose than in isoosmotic solns. of NaCl. H. G.

The oxygen requirement of certain aquatic animals and its bearing upon the source of their food supply. W. J. DAKIN AND C. M. G. DAKIN. *Brit. J. Exptl. Biol.* 2, 293-322(1925); *Physiol. Abstracts* 10, 231.—Expts. on goldfish did not support Putter's well-known hypothesis that fish under approx. natural conditions can and do obtain $1/2$ or more of their food requirements by the absorption of dissolved org. matter in the external medium. Addn. of asparagine and glycerol to tap water did not make any difference to the duration of life of goldfish deprived of particulate food, nor was the O consumption (detd. by Winkler's method) affected. Similar expts. were performed

on fresh-water mussels and axolotls. Putter's hypothesis of the nutrition of marine animals is criticized. H. G.

Studies on the comparative physiology of digestion. III. Secretion, digestion and assimilation in the intestine of *Ciona*. C. M. YONGE. *Brit. J. Exptl. Biol.* 2, 373-88(1925); *Physiol. Abstracts* 10, 221.—The histology of the alimentary tract in the tunicate *Ciona* is described in detail. Exts. digest starch, glycogen and sucrose, but not raffinose, cellulose, lactose or maltose. The optimum temp. of the amylolytic enzyme is between 42° and 43°, and it is destroyed at 64°. A lipolytic enzyme, and an enzyme which digests salicin and amygdalin, are present. Proteolytic digestion was only obtained in alk. and neutral medium with formation of albumoses, and no trace of amino acids was obtained after 14 days' digestion. Absorption mainly occurs in the mid intestine. Fat and glycogen are the principal storage products. H. G.

Temperature of heart rate in *Pterotrachea* and *Tiedemannia*. O. GLASER. *J. Gen. Physiol.* 9, 269-84(1925).—The thermal increment (μ) for intermediate temps. was 11,200 μ for *P. coronata* and 16,200 μ for *T. neapolitana*. At high temps., the values were 7300 and 7400, resp., whereas at lower temps. they were 22,000 and 23,000, resp. The theoretical application of the exptl. facts is discussed. C. H. R.

Variations in the internal p_H of the sea urchin egg during fertilization and division. P. REISS. *Compt. rend.* 181, 936-8(1925); cf. *C. A.* 19, 862.—The egg was crushed in a soln. of bromocresol purple while under view with the microscope. Tests with the unfertilized egg of *Paracentrotus lividus* Lk. showed an increase in the acidity from p_H 5.57 to 5.4. Upon fertilization the acidity diminished in a rhythmic manner, the max. points of acidity coinciding with the 1st, 2nd, 3rd and 4th divisions. L. W. RIGGS

Biologic action of X-rays of different wave lengths. A. DAUVILLIER. *Compt. rend.* 181, 1130-2(1925).—A criticism is made of Dognon's paper (cf. *C. A.* 19, 3326) particularly the method of measurement of the rays. L. W. RIGGS

The genesis of urates in the cells of orthopteracridians. CH. HOLLANDE. *Compt. rend.* 181, 1175-6(1925).—It was shown in 1914 that the urates in the adipose cells of Lepidoptera at the time of metamorphosis form around the nucleus and are not in the blood of the insect. The urates in Orthoptera are found in the protoplasm of cells specifically called *urate cells*, which are in intimate relation to the adipose cells. Injection of Na or NH_4 urate into the blood of the insect does not increase the urates in the urate cells, from which it is concluded that like the Lepidoptera, Orthoptera does not deposit urates from the blood, but that the urates are elaborated within the cell. L. W. RIGGS

Action of aqueous extracts and salts of eggs of the species on the spermatozooids of the russet frog (*Rana fusca*). H. BARTHÉLÉMY. *Compt. rend.* 181, 1183-6(1925). In no case was the presence of lysine or other substance of female origin found harmful to the male elements. Except in the cases in which the excess of NaCl, of salts or of KCN and the gang manifested their action, the exts. of the eggs were clearly favorable to the activity of the spermatozooids and to the prolongation of their life. The concn. in mineral and org. materials in the perivitellin liquid is the cause of the monospermia of normal eggs of the russet frog. L. W. RIGGS

Salinity of inshore oceanic waters of Australia, in relation to fishes. W. J. PHILLIPS AND F. J. T. GRIGG. *Proc. Linn. Soc. N. S. Wales* 50, 432-7(1925).—Analyses for the chloride content of samples of sea water from the shores of Australia and of New Zealand are given. Fresh water from rivers or rain destroys or retards the growth of certain marine organisms which help to form the ultimate food of fishes. The percentage of fishes which enter brackish water from choice is very small. The largest fishing grounds are away from the mouths of large rivers. L. W. RIGGS

Present pigmentary problems. II. Relation of pigmentation to digestion. Interpretation of cases of homochromia. JEAN VERNE. *Rev. gen. sci.* 36, 705-11(1925). cf. *C. A.* 20, 928.—A review of the work of others and some exptl. results of V. on various lower organisms are given. L. W. RIGGS

Action of dyes used in paper making on the animal life of streams (HAEMPEL) 14.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Food Investigation Board, report for the year 1924. *Dept. Sci. Ind. Research* 1925.—The titles and authors of the principal studies of the year 1924 are given in this abstract. A few of the papers have appeared in scientific journals and many of them refer to in-

completed research work. The theory of freezing: I. Effect of the rate of cooling and thawing upon the final distribution of water in a gelatin gel. T. MORAN AND H. P. HALE. 5-12. II. The velocity of ice crystallization through supercooled gelatin gels. F. H. CALLOW. 12-4. III. Changes of state in white and yolk of hens' eggs which have been frozen, and the effect of temperature upon the life of the egg. T. MORAN. 14-5. IV. Osmotic pressure of solution of protein. G. ADAIR. 16. Preservation of eggs and meat. I. The preservation of eggs. T. MORAN AND J. PIQUE. 16. III. The lactic acid production in muscle. D. L. FOSTER. 16-7. IV. Succinic acid in muscle. D. M. The problems of flour milling chemistry. R. J. CLARK. *Northwestern Miller* 145, 572(1926).—It is necessary that the successful mill chemist have exact knowledge of his raw material, its conversion into flour, and the proper way to handle the flour to produce the max. results. The wheat kernel contains starch, fat, potash, soda, lime, magnesia, proteins, moisture, enzymes, vitamins, various acids, cellulose, sugars and lecithin. Any one of these subjects offers a topic for research, also a chemist must test commodities used by the mill such as lubricating oil, soap, paint, water and coal. Upon flour the chemist tests for moisture, ash, protein and frequently viscosity and hydrogen-ion determinations are also made. Some quick test is needed to furnish information on the quality of wheat before it is milled. L. H. BAILEY

Irrigation as a factor in modifying the composition of grain. J. E. GREAVES. *Northwestern Miller* 145, 658(1926).—Expts. conducted at the Utah Agr. Expt. Station show that wheat, oats and barley grown on irrigated land contain less protein than those grown on non-irrigated, but the ash content is the reverse. The P, K, Ca and Mg contents of grains grown on the irrigated lands are increased. Considering the extent to which irrigation water has modified the mineral elements in these grains, it is easy to see how a ration of irrigated grain would carry sufficient Ca and P if fed to swine to produce strong normal bones, which is not the case with corn alone. L. H. BAILEY

Effect of fine grinding upon flour. C. L. ALSBERG AND E. P. GRIFFING. *Cereal Chemistry* 2, 325-44(1925).—Over-fine grinding of flour reduces the baking quality. The authors sought an explanation of this by detg. the effect on cold water ext. of the flour, the rate of diastatic conversion of starch in flour, the effect on quantity and quality of gluten washed from flour, and the extent to which overgrinding injured the baking strength. They found that overgrinding injures the starch granules so that a part of the starch swells and disperses when the flour is doughed. Cold H₂O ext. is increased because of the dispersed starch. There is increased diastatic starch inversion and consequently an increased initial rate of fermentation follows. Severe overgrinding injures flour for baking purposes despite increased absorption due to swelling of starch granules. Evidence is presented that it also injures the gluten. Moderate overgrinding may injure the starch granules without much affecting the gluten. In 1 flour examd., absorption was appreciably increased without a material effect upon the baking strength. RUTH BUCHANAN

Correlation of test weight per bushel of hard spring wheat with flour yield and other factors of quality. C. E. MANGELS AND T. SANDERSON. *Cereal Chemistry* 2, 365-9(1925).—The use of the test wt. per bushel as a grading factor is justified by its relation to flour yield and to a lesser extent by the relation of test wt. to color of flour or bread. Test wt. and flour yield show a high positive correlation. Test wt. and color of bread show a positive correlation. But the coeff. varies with different crops. No significant correlation is found between test wt. and loaf vol. on water absorption of flour and test wt.

RUTH BUCHANAN

Comments on the use of calcium acid phosphate as an improver of soft wheat biscuit flour. G. L. ALEXANDER. *Cereal Chemistry* 2, 370-9(1925).—Four flours were divided into 4 portions and stored for 3 months. In 1 portion of each flour was incorporated 0.5% of CaHPO_4 and in the other 3 portions of each flour were incorporated resp., 1.00% and 1.50% acid phosphate and a standard leavening formula. Portions of the plain flours were used as controls. At the end of 3 months it was found that in the bleached flours contg., resp., 1.0% and 1.5% of added phosphate, a slight disagreeable odor prevailed. The unbleached flours contg. 1.5% added phosphate had a slight odor. All other samples were sweet. Tests indicate that sound flours under normal conditions of storage will not deteriorate in a reasonable time if treated with not over 1.0% of CaHPO_4 . Unbleached flours can carry the action of somewhat more added phosphate than bleached flours. Baking tests with flours contg. 0.5% added phosphate and 1% added phosphate were found to improve the dough quality, biscuit vol., crumb texture and color. One % added phosphate showed more improvement than 5% but principally on crumb color. Lactic acid was found to improve biscuits also. Lactic acid does not increase the adsorption of dough as phosphate. Effect of phosphate is believed to be due to increase of H-ion concn.

RUTH BUCHANAN

Wheat and flour studies. V. Plasticity of simple flour in water suspensions. P. F. SHARP. *Cereal Chemistry* 3, 40-55(1926).—An app. much more simple and less costly than the usual app. for detg. plasticity is described. A particular flour-in-water suspension was found to be plastic when it contained 9% or more of flour by weight on the dry basis. A bibliography is given.

RUTH BUCHANAN

Detection of minute amounts of naphthalene in flour. A. K. EPSTEIN AND B. R. HARRIS. *Cereal Chemistry* 3, 60-2(1926).—A reliable method is described for the detection of naphthalene in flour in concn. as low as 1.5 to 1.0 parts of naphthalene per 100,000 parts of flour. This is based on a 50-g. sample of flour. By using larger sample, smaller quantities of naphthalene might be detected.

RUTH BUCHANAN

(Flour) ash. H. L. THOMPSON. *Am. Miller* 54, 160(1926).—The ash of a patent flour contains approx. P_2O_5 50, K_2O 35, CaO 7, MgO 7, Na_2O $\frac{3}{4}$ and Fe_2O_3 $\frac{1}{2}$ %. The Mg increases in the lower grades while the Ca decreases. The other constituents remain almost const. The percentage of ash is only indicative of flour grade. Usually a flour with high ash content is low in grade. There is no close correlation between the ash content and baking quality. Ash detn. is of great value in the control of the operation of a mill. Ash content of flour depends on (1) the ash content of the wheat (2) the cleaning of the wheat, (3) tempering, (4) grinding, (5) bolting or sifting, (6) operation of the purifiers, (7) proper sepn. and blending of the mill streams. A method is given for making an ash detn. of flour.

L. H. BAILEY

(Flour) ash—its determination and significance. C. O. SWANSON. *Am. Miller* 54, 70-1(1926).—There is an annual variation in the ash content of wheat. Light test weight wheat has more ash than heavy. As wheat ripens the kernel fills out decreasing the proportion of bran to endosperm, and since this has less than one-tenth as much ash as the bran, the percentage as a whole decreases. High ash in flour may be traced to two sources: first, the bran specks which are made fine enough to pass the flour bolting cloth; and second, the fine invisible material high in ash. This latter does not seem to affect the color value, while the former does. The effect on color is no doubt the greatest objection to high ash. A high-ash flour is dark colored compared with a low-ash flour. The dark specks or dark color are associated with lack of purity in flour. Proper humidity control maintains toughness in the bran and prevents its pulverization, and hence produces a flour with low ash content. The same mineral elements present in wheat are present in flour only in smaller amts. Wheat is deficient in Ca, one of the important mineral elements needed by the body.

L. H. BAILEY

Determination of the ash content of flour. A. GOSKE. *Z. Nahr. Genussm.* 50, 428-9(1925); cf. *C. A.* 19, 3327.—1.5 g. of finely powd. pumice is calcined in a small Pt dish, cooled, and 0.8-1.0 g. flour is added. After moistening and stirring, the mixt is heated over a low flame, then over a stronger flame and finally in a muffle furnace. The dish is cooled, weighed, and may be used for a second detn.

W. J. H.

The nutritional deficiencies of whole wheat flour. E. M. NELSON AND W. H. STROWD. *Northwestern Miller* 145, 896(1926).—Authorities are quoted showing that wheat and other seeds are deficient in Ca, P, Na and Cl as well as vitamins. It is scarcely practicable for a man to eat enough leafy foods to enable him to succeed with a strictly vegetable diet. Lack of sufficient Ca is one of the most important deficiencies in such a diet, and a great abundance of leaf is necessary to supply this element in adequate amounts. Self-rising flour contains approx. 9 times as much Ca and 2.25 times as much P as entire wheat flour. Foods prepd. from self-rising flour will help eliminate deficiencies in the American diet.

L. H. BAILEY

Some factors influencing the strength of wheat and flour. J. S. REMINGTON. *Ind. Chemist* 2, 35-8(1926).—The writer's methods for detg. wet and dry gluten and method of testing stretch of gluten are given. Method of testing the flour by making a dough of flour, H₂O and yeast is described.

RUTH BUCHANAN

The nutritive value of Philippine cereals. I. The vitamin B content of glutinous rice, dead rice and adlay. F. O. SANTOS AND E. G. COLLADO. *Philippine Agr.* 14, 473-7(1926).—The compn. of the dead rice, glutinous rice and adlay was H₂O 13.65, 13.27 and 12.92; ether ext. 0.60, 0.33 and 1.46; ash 0.91, 0.30 and 1.15; protein 9.34, 5.66 and 10.46; crude fiber 0.38, 0.20 and 0.51; and carbohydrates 75.14, 80.24 and 73.50 %, resp. Glutinous rice and adlay supplied sufficient vitamin B for the growth of rats and dead rice did not. Six citations are appended.

A. L. MEHRING

Residual sugar of bread. C. B. MORISON. *Baking Tech.* 4, 328-30; *Cereal Chemistry* 2, 315-7(1925).

RUTH BUCHANAN

Some variable factors of bread production. C. G. HARREL. *Cereal Chemistry* 3, 1-18(1926).—Trouble in bread making is due not to the flour but to certain variables not properly controlled. Absorption, correct panning, time and speed of mixing and temp. of the finished dough are factors to be watched carefully. Fermentation is the most important single factor in bread production. Factors affecting fermentation vary according to whether there is a straight or sponge dough. A scientific discussion of fermentation of both doughs is given. The action of acids in the dough is of great importance. From a bread-producing standpoint this necessitates a classification of the dough ingredients into (1) factors resisting an increase in acid formation, the buffer value of the dough; (2) forces tending to overcome this buffer value, chiefly the yeast and acid accelerating salts. Measurements of these factors are given.

RUTH BUCHANAN

Organic acids in doughs. A. H. JOHNSON. *Cereal Chemistry* 2, 345-64(1925).—The factors involved in the increase of the acidity of flour-water suspensions, cracker sponges, and bread doughs fermented with yeast are (1) CO₂ produced by yeast, (2) acid phosphate salts produced by phytase-phytin phenomena, and (3) org. acids produced by the yeast or other organisms present in the media. CO₂ produced by yeast and acid phosphate salts resulting from phytase acidity have very slight effect on the final acidity of flour-water suspensions and cracker sponges fermented with yeast. CO₂ present in a bread dough is the most important single factor affecting its H-ion concn. and titratable acidity. Lactic and acetic acids are the only org. acids found in flour preps. fermented with yeast. Lactic acid occurring in the flour-water suspensions represents 70-96% of the org. acid present, the remainder being acetic acid. The proportion of acetic acid appears to increase with increase of fermentation period. Lactic acid varies from 78 to 95% of the org. acid of a cracker sponge and acetic acid constitutes the remainder. A bibliography is given.

RUTH BUCHANAN

A study of the determination of the neutralizing value of monocalcium phosphate. HOWARD ADLER AND G. E. BARBER. *Cereal Chemistry* 2, 380-90(1925).—The present methods of detg. the neutralizing value of monocalcium phosphate have been studied with a view to estg. their merit in calcg. the proportions of phosphate and carbonate to be used in baking. Titration methods can be used for these requirements. The method which involves the detn. of the ion concn. of the baking powder residue does not give applicable results and further does not take into consideration the nature of the reacting substances. Exptl. evidence has been advanced to show that the reaction between monocalcium phosphate and soda does not stop at a p_{H} of 7.0 nor at the dicalcium stage. It is shown that dicalcium phosphate can be used as a baking acid, giving satisfactory products when constituting up to 25% of the baking powder. Within the limits of baking practice residual CO₂ does not indicate undecomposed soda and is not directly related to the p_{H} of the residue. Residual CO₂ is present to a large extent in an insol. form.

RUTH BUCHANAN

Method for a graphic record of texture, volume and contour of cakes. ALICE M. CHILD AND DAISY I. PURDY. *Cereal Chemistry* 3, 57-60(1926).—Mix together thoroughly.

equal parts of mimeograph ink, glycerol and H_2O . Cut a piece of blotting paper slightly larger than the piece of cake of which a print is to be made. Allow the blotter to absorb all the ink mixt. Place this, ink side up, on a board and work the ink into the blotter with a camel's hair brush. By means of thumb tacks stretch tightly a piece of thin, soft, smooth, even-textured cloth over this. Allow it to stand 5 or 10 min. to absorb ink. All excess ink should be wiped off. Cut a piece of cake, $\frac{1}{2}$ to $\frac{3}{4}$ in. in thickness, with a clean cut surface. Using the slice of cake as a stamp and the blotter as a pad press lightly with the tips of fingers over the whole surface in order that every cell may have a film of ink. Transfer the cake to the paper on which the print is to be made. Illustrations are given.

RUTH BUCHANAN

The standardization of the methylene blue test for milk control work. E. G. HASTINGS. *13th Ann. Rept. Intern. Assoc. Dairy Inspectors 1924*, 268-75.—H. compares foreign and American tablets. H. recommends tablets of $\frac{1}{2}$ and $\frac{1}{4}$ strength of foreign to prevent loss by spoilage of soln. H. classifies milk according to time of reduction

GEORGE R. GREENBANK

The use of eosin methylene blue culture medium in milk examination. MRS. EDITH L. MOORE. *13th Ann. Rept. Intern. Assoc. Dairy Inspectors 1924*, 186-8.—M finds this medium differentiates the colon bacillus from lactis aerogenes. The colon bacillus gives a fluorescence around colonies and the lactis aerogenes brownish centers

GEORGE R. GREENBANK

A critical investigation into the thermal death point of *Bacillus tuberculosis* in milk with special reference to pasteurization. F. W. C. BROWN. *13th Ann. Rept. Intern. Assoc. Dairy Inspectors 1924*, 67-73.—No difference was found in the thermal death point of human and bovine strains. 60° for 20 min. was sufficient to kill most all strains. Twenty-five different strains were studied.

GEORGE R. GREENBANK

Copper in milk and its relation to vitamin potency. *13th Ann. Rept. Intern. Dairy Inspectors 1924*, 37-51.—Following the work of Hess and Weinstock the comm. finds that the Cu in milk averages 2.5 parts per million. This is not sufficient to cause alarm, but should be a warning against equipment in poor condition. Several biologists report only the usual effects of heavy metals but not Cu as specific.

G. R. G.

The practicability of the Coolidge p_H test in the improvement of city milk supply. H. R. ESTES. *13th Ann. Rept. Intern. Assoc. Dairy Inspectors 1924*, 212-4.—E. detcs. the p_H developed by using a neutral broth contg. bromothymol, adds 1 cc. milk and incubates for 8 hrs., then compares it with standards. This method is more rapid than bacterial count.

GEORGE R. GREENBANK

Interpretation of certain empirical standards in their application to Irish butter. G. BROWNLEE. *Sci. Proc. Roy. Dublin Soc.* **18**, 49-58(1925).—Examn. of 127 samples of butter confirmed B.'s earlier contention that a Reichert-Wollny value of 24 is too high to be taken as the limit below which it is to be assumed that the butter has been adulterated. It is suggested that the general adoption of the practice of winter dairying would prevent the occurrence of abnormal Reichert-Wollny figures for pure Irish butter, for the effect of advancing lactation in causing depression of the Reichert-Wollny value can, to some extent, be counteracted by liberal treatment of the cows as regards feeding and shelter. No other tests (e. g., Polenske value, Koettstorfer test, Avelle-Lallemand test, or Zeiss butyrefractometer reading) could be considered as giving any more reliable information than the Reichert-Wollny value.

B. C. A.

Phytin content of foodstuffs. H. P. AVERILL and C. G. KING. *J. Am. Chem. Soc.* **48**, 724-8(1926).—The phytin contents of 57 samples of foodstuffs have been estd by the method of Heubner and Stadler (*C. A.* **8**, 3569). It was found preferable to use 2% HCl for extrn. Heating, soaking and steaming brought about a very perceptible decrease in the amt. of phytin as estd. by titration. The course of purification of phytin when sepd. by Anderson's method was studied to show the effect of the various steps on the loss and purity of the different fractions.

C. J. WEST

Variations in the mineral content of cabbage and sauerkraut. W. H. PETERSON, C. A. ELVEHEJEM and L. A. JAMISON. *Soil Science* **20**, 451-7(1925).—Eighteen samples of cabbage from New York, Ohio, Illinois and Wisconsin showed the following variation in compn., Ca 0.029-0.056, P 0.017-0.057, Fe 0.00017-0.00059, sugar 2.91-4.20 and N 0.15-0.24%. Samples high in Ca were also high in Fe. No relationship was found between the variation in these elements and P. Early samples contained more sugar and less N than the late samples. Sauerkraut made from this cabbage showed similar variations in compn. The kraut juice contained approx. the same percentage of food constituents as the kraut itself. The loss in minerals in making kraut ranged from 10 to 20%.

R. BRADFIELD

Relationship of incubation temperature to viability, rate of growth and toxin produc-

tion of *Cl. botulinum* in different vegetables. W. B. STARIN. *J. Infectious Diseases* 38, 106-14(1926).—Temps. of 20° and 25° are equally suitable for the growth of *Cl. botulinum* and for the production of toxin in such vegetables as corn, string beans, peas and spinach. The rate of development is somewhat more rapid at 25° than at 20°, although in each case the toxicity eventually reaches the same level. A temp. of 10-12° is not suitable for growth of *Cl. botulinum* nor for the production of a potent toxin, even when incubation is extended to 5 mos. Death of the organism does not occur at any temp. used, even after 3 mos. incubation. Even in those media in which no evidence of growth or toxin production could be detected, transplants to a suitable medium, such as beef heart, resulted in abundant growth of the organism with normal toxin production. Disintegration of the medium parallels the production of toxin, although in some instances lethal doses of toxin may be present with practically no changes in the gross appearance or in the odor. The 4 vegetables used rank as follows in the rate of toxin production, and in the quantity of toxin produced: corn peas, string beans, spinach. The high initial acidity of the beans and spinach may be the responsible factor for the slight growth and toxin production in these media.

JULIAN H. LEWIS

Toxin production by *Clostridium botulinum* in canned foods. LUTHER THOMPSON WITH F. W. TANNER. *J. Infectious Diseases* 37, 344-52(1925).—By testing the growth of *Clostridium botulinum* in various canned foods it was hoped to indicate those foods that are potentially dangerous, although some of them might never have been reported as the cause of food poisoning. Those foods found to be regularly toxic after inoculation with all strains of the organism were: red kidney beans, lima beans, hominy, peas, sweet potato, salmon and shrimp. Those irregularly toxic were: asparagus, beets, pumpkin and spinach. The acid fruits and the very acid vegetable products, such as sauerkraut and dill pickles, never became toxic. The irregularity of toxin production in asparagus, beets, pumpkin and spinach is probably explained by their reaction. The reaction in certain canned vegetables is greatly affected by the quality of the material put in the cans. Expts. with spinach show that a small amt. of rotted material will reduce the acidity to a point where *Clostridium botulinum* can grow and develop a toxin.

J. A. KENNEDY

Investigation of commercial apple juices and pectin preparations. HANNS ECKART. *Z. Nahr. Genussm.* 50, 405-15(1925).—A discussion of the compn. of com. pectin preps., with tabulated analyses of several such preps.

WILLIAM J. HUSA

Fish meals. II. Changes occurring in the water-soluble nitrogen and in the amount of water-soluble phosphorus with different methods of treatment and storage. W. L. DAVIES. *J. Soc. Chem. Ind.* 45, 25-9T(1926); cf. *C. A.* 20, 462.—Samples of 5 types of fish meal were stored (a) in bags, in open vessels, and a dry warm state for 7 months, and (b) in a cold and a warm wet state for 3 weeks. Aq. exts. of these meals were examd. for initial acidity, water-sol. N, sol. P, etc. Acidity was increased by (b) and by mold growth in (a). Water-sol. N was generally increased by (b), except with meals B and E, and tended to diminish with (a), except with meal C. In every case more of the total N appeared in the alc. solns. obtained from the aq. exts., and this fraction was also a larger fraction of the H₂O-extractable N. Some decarboxylation occurred with cold wet storage and some deamination during warm dry storage. (b) increased the amt. of volatile base in the water-sol. fraction. (a) caused a loss of volatile base. Warm dry treatment caused the greatest increase in the amt. of sol. P. Mold growth caused a decrease in sol. P. and an increase in initial acidity. (b) caused all the meals to become unwholesome; neither open vessel nor warm dry treatment caused any fetid odor in spite of mold growth in some cases. Bag storage caused oily meals to become rancid and some white meals to become fetid.

Heat transfer from moving gases to tubes. H. REIHER. *Z. Ver. deut. Ing.* 70, 47-52(1925); *Mitt. Forschungsarbeiten* No. 269.—Air was blown through a heater, then through a diffuser, then across H₂O-cooled pipes at right angles to the line of flow. Gas temps. before and after these pipes were measured with Pt resistance thermometer grids, tube wall temps. were measured with thermocouples. Radiation from air to tubes was calcd. and allowed for. Tubes of 4.6-28 mm. outside diam. were used. For one row of tubes $\alpha = C(\lambda_m/d)(W_m d \rho_m / \mu_m)$ 0.56 Cal. per sq. m. per °C. per hr., where λ_m and μ_m are thermal conductivity and viscosity of the air in metric units at mean film temps., ρ_m is density in kg. per cu. m., d is pipe diam. in meters, and W_m is mean gas velocity in m. per sec. For this case $C = 0.35$. For

successive rows of tubes in line the exponent is 0.654 and $C = 0.122$ for 2 rows, 0.126 for 3 rows, 0.129 for 4 rows, and 0.131 for 5 rows. For successive rows of pipes staggered the exponent is 0.69 and $C = 0.100$ for 2 rows, 0.133 for 3 rows, 0.123 for 4 rows, and 0.131 for 5 rows.

W. L. BADGER

The absorption of chemical mist. H. REMY. *Z. angew. Chem.* 39, 147-50 (1926).—The ease of absorption of chemical mists is a function of their vapor pressures. A distinction must be made between "dry" and "damp" mists, as they act in very different ways. Particles of "dry" mists are generally of the same magnitude as colloid particles; they may be called "colloid dust." The most efficient means for removing mist is by the use of high-tension electricity. Exptl. results show that absorption bottles with H_2O , KOH soln., gas mask charcoal, etc., are less effective absorbents for moist NH_4Cl than filter paper, absorbent cotton and layers of asbestos in Gooch crucibles. This is accounted for on the assumption that these inert particles carried along in a gas stream do not come into contact with the absorbent as frequently as do gaseous mols. The particles of mist within a bubble passing through a liquid may not come into contact with the liquid at all. Confirmatory tests are reported for expts. with dry and damp SO_2 passing through various absorbents. The smaller the size of the particle, the more easily is it absorbed. Passed through filter paper damp mists are held back better than dry. Most important is it that intimate contact between mist and absorbent be effected.

W. C. EBAUGH

Engineering problems in refrigeration. EZER GRIFFITHS, J. H. AWBERY AND A. SNOW. *Food Investigation Board, report for the year 1924. Dept. Sci. Ind. Research* 1925, 68-80.—The topics studied were the inflammability test on heat-insulating materials, phys. properties of substances used as refrigerants, hygrometry, industrial forms of app. for the detn. of the CO_2 content of the atm. in a refrigerated enclosure, "air-conditioning" app., instruments for indicating the rate of flow of NH_3 or brine in a refrigerating plant circuit, and app. for demonstrating the circulation of air currents among stacked boxes in a cooled enclosure.

L. W. RIGGS

English-German conversion of technical units of measure. TH. HOFFMANN. *Chem. App.* 13, 30-1 (1926).—A table.

J. H. MOORE

Literature of carbon monoxide poisoning. R. R. SAYERS AND SARA J. DAVENPORT. *U. S. Public Health Bull.* 150, 54 pp. (1925).—A review under the headings: historical statement, occurrence, symptoms, pathology, percentage of CO dangerous to breathe, methods of detecting CO in blood and in air, treatment, prevention, and bibliography (141 references).

C. M. SALLS

Prophylaxis in industrial lead poisoning. DAVID MCKAIL. *J. Ind. Hyg.* 8, 74-7 (1926).—Although inhalation of fumes or dust is the main channel of entrance, absorption of Pb takes place mainly through the alimentary tract. Pb dust from the upper respiratory passages is swallowed and dissolved by the HCl of the gastric juice. Prophylaxis lies in removal of dust at point of origin; avoidance of raising or inhaling dust; scrupulous cleanliness of hands, face, teeth and clothing; mouth-washing; an albuminous meal before starting work; and a sol. sulfate cathartic once or twice a week. The sulfate soln. forms physiologically inert $PbSO_4$.

C. M. SALLS

Four cases of poisoning by mononitrochlorobenzene and one by acetanilide, occurring in a chemical works—explanation of the toxic symptoms produced. ARNOLD RENSIAW AND G. V. ASHCROFT. *J. Ind. Hyg.* 8, 67-73 (1926).—Poisoning followed exposure of only a few days to fumes rising from crystg. trays contg. *o*- and *p*- $C_6H_4ClNO_2$ made by nitration of $PhCl$. Apparently $C_6H_4ClNO_2$ is a cumulative blood poison causing cyanosis and collapse, probably due to reduction in the blood to the highly toxic and very reactive $C_6H_4ClNH_2$. Users of alc. apparently suffer most. One case from the crushing of acetanilide for *p*-nitroaniline manuf. was probably due to 0.1 to 0.2% $PhNH_2$ impurity. Local ventilation and covering of the crystg. trays with tightly fitting covers is recommended.

Evaporating and distilling liquids. SOC. GENERALE D'EVAPORATION PROCÉDÉS PRACHE ET BOUILLON. Brit. 242,259, Oct. 31, 1924. Air or gas is passed through heated liquid to be evapd. and through a condenser the condensate from which is used to preheat the liquid. An app. is described.

Heat-exchange system for fractional condensation of oil vapors, etc. J. E. BELL. U. S. 1,573,129, Feb. 16.

Heating glass, metals, etc., to render them workable. J. W. VAN METTER. U. S. 1,572,975, Feb. 16. Heat is generated in a non-oxidizing atm. by the chem. reaction of Cl on Zn, Fe, Pb or As, etc., which may be placed within a glass tube or other article to be heated.

Electric insulation. E. B. WEDMORE, W. S. FLIGHT AND BRITISH ELECTRICAL & ALLIED INDUSTRIES RESEARCH ASSOCIATION. Brit. 236,619, April 3, 1924. Tangled filaments of glass, slag-wool or fused SiO_2 are arranged in layers and impregnated with a phenol-formaldehyde resin, and compressed.

Electric insulation. E. HAEFFELY ET CIE ART.-GES. Brit. 236,937, July 12, 1924. Wood is satd. with synthetic resin, forced into the pores of the wood under pressure while in liquid condition, and the resin is then hardened by heat and pressure.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Chlorination of water. L. H. ENSLOW. *Pub. Health Eng. Abstracts* Jan. 30, (1926).—The modern application of Cl to the destruction of bacterial life, algae prevention, oxidation of S gases and Fe, and in taste and odor prevention is discussed.

MARTIN E. FLENTJE

Determination of chloride in water. H. W. VAN URK. *Z. anal. Chem.* 67, 281-8 (1925).—Mohr's well-known titration method is discussed critically on the basis of the mass-action law and as a result of the mathematical study certain improvements in technic are suggested. The concn. of the CrO_4^{--} should lie between 0.7 and 1.5 millimoles per l. The p_H value of the water titrated should lie between 7 and 11. If the water is alk. toward tropeolin O or acid toward rosolic acid, it should be neutralized. The most suitable p_H value is 9, at which point phenolphthalein is barely pink. MgO is unsuitable as a neutralizing agent but NaHCO_3 soln. is advantageous. Water satd. with Mg(OH)_2 has a p_H value of about 11. W. T. H.

Comparative study of the oxidation number of water by the Kubel-Tiemann test and of its chlorination number. KARL KREISER. *Gas u. Wasserfach* 69, 42-3, 65-9 (1926).—The detn. of org. matter in H_2O free from aluminous decompn. products may be made by KMnO_4 oxidation (Kubel method) or by chlorination (Froboese method), but if the water is contaminated by sewage the chlorination method must be used for exact results. Comparisons of the 2 methods are given, for various types of contaminated waters, by 15 tables. In certain cases the chlorination of the raw water increases its filterability by the change in the colloidal nature of its org. matter.

W. B. PLUMMER

Chemical relation of salt dome waters. H. E. MINOR. *Bull. Am. Assoc. Petroleum Geol.* 9, 38-41(1925).—The Cl content of ground waters from Texas and Louisiana salt domes has been found useful in identifying the source of the waters and in correlation of water-bearing sands. The amt. of Cl is lowest in the near-surface water and increases downward, reaching satn. near the salt of shallow cores but in domes of the deep-seated type rising gradually at a rather uniform rate below the 2000-foot level. In several cases structure of the rocks is clearly suggested by Cl concn. in ground waters.

C. L. C.

Occurrence of sulfur waters in the Gulf Coast of Texas and Louisiana, and their significance in locating new domes. F. F. HENNIGER. *Bull. Am. Assoc. Petroleum Geol.* 9, 35-7(1925).—The occurrence of comparatively shallow waters showing varying

concns. of sulfates and H_2S throughout the salt dome belt of Texas and Louisiana, is more or less general. Geological examns. of a no. of localities where high concns. were found over small areas show the mineralization to be due in most instances to surface conditions and not to buried domes. Actual drilling has practically condemned several of the most promising areas, emphasizing the fact that new salt domes are not readily located on the evidence of S water alone. That it becomes increasingly difficult to find additional domes is apparent when one considers that of the 40 known domes in the Gulf Coast area, 37 were found from 1901 to 1913. Cf the other three, two were found in 1917 and the other in 1922. Since the discovery in 1917 of the Hager-Martin dome in sec. 28, T. 9 S., R. 7 E., St. Martin Parish, Louisiana, approx. 675 wildcat wells have been drilled in search of new domes on the coast, involving an expense estd. at \$20,000,000, exclusive of the cost of leases and overhead expenses. Yet only 1 new dome has been found during this period and it has not yet proved profitable commercially as a source of oil. C. L. C.

Santa Fe Springs Field, California (water problems). R. R. TEMPLETON AND C. R. MCCALLON. *Bull. Am. Assoc. Petroleum Geol.* **8**, 190-2(1924).—Surface waters are typical alkaline waters, with total solid content of 500-1000 parts per million. An av. sample contains total solids 691.5, Na 138.7, Ca and Mg 118.1, SO_4 106.1, Cl 65.0, HCO_3 and CO_3 263.6. Waters of Foix and Bell zones are mixts. of altered connate and meteoric waters; that of the Meyer zone is an altered connate water with little or no meteoric water. Foix water is distinguished from Bell water by higher content of Ca and Mg. Foix water has an av. alk. earth content of 2.5 to 4.0%, while Bell zone water averages 1.5 to 2.0%. The alk. Bell zone water is characterized by low primary salinity, 44%, with correspondingly high carbonate-chloride ratio. Is distinguished from Foix water by lower primary salinity, higher primary alky., lower alk. earth content, higher carbonate-chloride ratio and usually higher concn. It is easily distinguished from Meyer water by lower concn., lower primary salinity, higher primary alky. and higher carbonate-chloride ratio. It is distinguished from other Bell waters by lower primary salinity, higher primary alky. and higher carbonate-chloride ratio. Saline Bell zone water closely resembles the Meyer water, and is distinguished from the Foix water by higher concn., lower alk. earth content and higher primary salinity. It is distinguished from other Bell waters by higher concn., higher primary salinity, and lower carbonate-chloride ratio. It differs from Meyer water by lower concn., lower primary salinity, and higher carbonate-chloride ratio. Meyer water is an altered connate water with the highest dissolved salts concn. in the field. C. L. C.

Maintenance and operation of water supply works. W. H. DITTOE, *et al.* *Am. J. Pub. Health* **16**, 136-9(1926).—The reduction of typhoid fever and the pollution of surface streams are making a demand for greater efficiencies in water purification. More careful control by technical service and by state labs. is advocated. K. C. B.

Isolation of the colon group in water. N. J. HOWARD AND R. E. THOMPSON. *Eng. Contr.* **64**, 597-606(1925).—See C. A. **19**, 2541. C. C. RUCHHOFF

Antimicrobial properties of various river or sea waters. Bacteriophage power. F. ARLOING, SEMPE AND CHAVANNE. *Bull. Acad. Med.* **43**, 7(French); *Pub. Health Eng. Abstracts*, Jan. 30, 1926.—Evidences of anti-microbial action of certain river or sea waters have been found. The lytic action of these waters is attributed to the presence of multivalent bacteriophage, rather than to nonspecific causes. M. E. F.

The action of dyes used in paper making on the animal life of streams. O. HANMPEL. *Z. Nahr. Genussm.* **50**, 423-6(1925); cf. C. A. **6**, 781.—Fish and other lower water animals were kept for 1-10 days in solns. contg. various dyes in concns. of 1:100,000-1:1,000,000. Cotton red 4B, orange II, new fuchsin 90, safranin OF and naphthamine RON proved harmless; auramine conc. and canary-yellow 40 were slightly poisonous; methyl violet 34B80 was poisonous; Victoria blue B extra, brilliant green cryst. and benzol green EO were very poisonous. WILLIAM J. HUSA

Purification of boiler feed water. WM. E. SMITH. *Facts about Sugar* **20**, 1168-9(1925).—Proper cylinder lubrication and efficiency of various types of equipment for removing oil are discussed. T. MARKOVITS

Prevention of scale and rust. DE GRAHL. *Gesundh. Ing.* **49**, 45-6(1926).—The pptn. of normal carbonates is prevented by the addn. of a sol. chloride to the water, sufficient being added to change part of the Ca content to $CaCl_2$. This method is recommended for household installations. MARTIN E. FLENTJE

Loss of nitrogen in the purification of effluent waters by means of activated sludges. LUCIEN CAVEL. *Compt. rend.* **181**, 1101-3(1925); cf. C. A. **19**, 1020.—To emphasize the loss and to enable the N to be detd. with greater precision, $(NH_4)_2SO_4$ was added to

effluent water contg. 20% of activated sludge. The total N in the original water-sludge mixt. 189.28 mg. per l., N added as $(\text{NH}_4)_2\text{SO}_4$ 119.5, total 308.78. After bubbling air through the mixt. until the passed air gave no further Nessler test, there was found org. N 95.20, N as nitrates and nitrites 74.60, N as NH_4 8.0 mg., total 177.80, showing a loss of 42.4% of the N.

L. W. RIGGS

Treatment of packing-house sewage. W. C. MOOR AND W. P. WAYNE. *Ind. Eng. Chem.* **18**, 239-42(1926).—Several attempts have been made to dispose of heavy wastes from the packing-houses of Armour and Swift and of the stock yards at Ft Worth, Texas. By the scheme adopted the sewage from the 3 contributors is passed through vertical bar screens, $3\frac{1}{2}$ in. apart, and then through North screens with 8 in. mesh. Two screens of Monel metal are proving better than 2 screens of brass. The liquid is passed through Dorr clarifiers and then to the city sewer. 74% of the suspended matter is removed. Screenings and settlings are blown by ejectors to waste land near the plant. Grease is removed by live steam from the screens and by skimmer from the tanks. It has thus far been wasted. The effluent passes to the city sewer and the city disposal plant, which contains screens, grit chambers, Imhoff tanks, sprinkling filters, and Dorr clarifiers. The packing-house effluent increases both the org. and inorg. content of the sewage to above the av. of domestic sewage. The plant is rated to handle 7,000,000 gallons of domestic sewage and can handle about 5,000,000 gallons of the mixt. An addn. to the plant will be necessary.

EDWARD BARTOW

Treatment of sewage at Manchester. E. ARDERN. *Annual Report, Manchester Rivers Dept.* **1925**, 465; *Pub. Health Eng. Abstracts*, Feb. 6, 1926.—Conditioning sludge with alum gave good results in filtration. Sludge in good condition when leaving the aeration plant could economically be conditioned by the combined use of acid and alum. Trade wastes, especially oily and tarry matter, cause operation difficulties.

M. E. F.

Activated sludge. Jamshedpur sewage-disposal works with special reference to the activated-sludge plant. F. C. TEMPLE AND V. N. SARANGDIAR. *Abstr. J. o' Eng. Inst. of Canada* **8**, 28(1925); *Pub. Health Eng. Abstrs.*, Dec. 26, 1925.—The activated-sludge system is remarkably well adapted to Indian conditions—both for sewage purification and for the production of fertilizer.

MARTIN E. FLENTJE

Laboratory apparatus for activated-sludge experiments. F. SIERP. *Gesundh. Ing.* **49**, 46(1926).—A description is given with illustrations and drawings, of an app. for exptl. studies of the activated-sludge method of sewage disposal.

M. E. F.

Soil acidity and survival of hookworm larvae. A critical commentary. L. FABIAN HIRST. *Indian Med. Gazette* **61**, 14-7(1926).—A criticism of the paper by Chandler, cf. *C. A.* **20**, 256. H. believes that ordinary acidity such as is found in agricultural soils increases the mortality of hookworm larvae. **Soil acidity and survival of hookworm larvae.** A. C. CHANDLER. *Ibid* 17-8.—A reply to Hirst's criticism.

L. W. RIGGS

Chlorine treatment of contaminated oysters. CHARLES KRUMWIEDE AND WM. H. PARK, et al. *Am. J. Pub. Health* **16**, 142-52(1926).—Sterilization of reasonably clean oysters contaminated with feces contg. *B. typhosus* was not successful. The treatment reduces the no. of *B. typhosus* present, but safe oysters can be obtained only from uncontaminated waters.

K. C. BEESON

The action of water containing NH_3 on pipes and boiler plates (TILGNER) **9**. Filter bed for water (U. S. pat. 1,572,398) **1**.

MORGENSTERN, EMIL: *Die Mineralquellen und Kurmittel des Iodbades Tölz mit bes. Berücks. ihrer Anwendungsweise.* 5th ed. revised and enlarged. Bad Salzungen: L. Scheermesser. 91 pp. R. M. 1.50.

Softening feed water for boilers. M. F. NEWMAN. U. S. 1,572,944, Feb. 16. After treatment of H_2O with reagents such as lime and Na_2CO_3 for neutralizing acids and pptg. hardening substances, it is further treated with NaHSO_4 or other acid sulfate to reduce its alky.

Treating boiler water to prevent incrustation. S. W. KOWALSKI. *Brit.* **242,276**. Oct. 30, 1924. An elec. treatment of H_2O is described for prep. H_2O for use in boilers or for brewing, dyeing, bleaching, ice-making, etc.

Apparatus for filtering water. W. PATTERSON. U. S. 1,572,076, Feb. 9.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Review of German literature on plant nutrition and soil science for 1924. E. A. MITSCHERLICH. *Soil Science* 20, 353-62(1925).—A series of abstracts arranged under the following headings: (1) Nitrogen as a growth factor; (2) phosphoric acid as a growth factor; (3) potassium as a growth factor; (4) lime as a soil factor; (5) soil reaction; (6) soil physics; (7) influence of CO₂ of atm. and of soil on plant growth; (8) further soil studies.

R. BRADFIELD

A movable lysimeter for soil studies. F. L. DULEY. *Soil Science* 20, 465-71 (1925).—The lysimeter and method of using it are described in detail. The chief advantages are: (1) It permits the use of natural soil column. (2) Its portability makes it possible to bring soils having different profiles to one place where they are subjected to similar environment.

R. BRADFIELD

A new soil core sampler. E. B. POWELL. *Soil Science* 21, 53-7(1926).—A sampler is described by means of which a cylinder of soil 6 in. in diam. and 12 in. long can be obtained in an undisturbed, natural condition. It consists of 2 concentric, tightly fitting, brass cylinders. The outer one is equipped with cutting knives which upon rotation by means of the heavy handle cut a rim 1½ inches wide around the outside of the sample desired. The inner cylinder does not rotate but as the sampler is drawn into the ground by its auger-like rotation, it slips over the soil core and protects it. Upon the removal of the sampler from the soil the core remains inside the inner cylinder. It is forced out by means of a plunger, the soil core is wrapped in screen wire and then dipped into melted paraffin. Samples thus protected may be transported to the lab. without any appreciable change in their natural structure.

R. BRADFIELD

The acetone method of extracting sulfur from soil. R. H. SIMON AND C. J. SCHOLLENBERGER. *Soil Science* 20, 393-6(1925).—The detn. of the residual S instead of the H₂O-sol. sulfates is recommended for studies of the rate of oxidation of elemental S in the soil. A modification of the acetone extn. method proposed by Pearson (C. A. 15, 960) and Dyer (C. A. 16, 3557) was found satisfactory. Twenty g. of air-dry soil is placed in the thimble of the extn. app. and compacted so that the acetone percolates through it slowly and uniformly. Fifty cc. of acetone is placed in the flask and kept at a temp. of about 56°. Sufficient heat is supplied to keep the acetone condensate percolating with 2-3 cm. pressure for 3-4 hrs. The acetone contg. the dissolved S is slowly distd. and recovered. The residual S is oxidized to sulfate with KMnO₄, the oxidized residue dissolved in 5 cc. concd. HCl for each g. of KMnO₄ used, the excess acid evapd., and residue taken up in a few drops HCl, dild. to 100 cc. and the S detd. by pptn. with BaCl₂.

R. BRADFIELD

Nitrification in soils. H. N. BATHAM. *Soil Science* 20, 337-51(1925).—Monomino-amino monocarboxylic acids are nitrified at about the same rate in Indian soils. Samples of each of the following amino acids containing 15 mg. of N were added to 100 g. of soil + 0.5 g. CaCO₃ at optimum moisture and the % nitrate detd. after 30 and 40 days incubation at room temp. The av. nitrification was: tryptophan 51.49%, phenylalanine 47.08%, α-alanine 45.46%, leucine 44.80%, tyrosine 39.70%, cystine 37.96%, (NH₄)₂SO₄ 67.46%. No correlation was found between rate of nitrification of these pure org. compds. and their N:C ratio. The presence of S in cystine seems responsible for its depressive influence on nitrification. The nitrate content of natural soils fluctuates widely but regularly at different periods of the year. The nitrifying organisms remained active in stock soil for over a year.

R. BRADFIELD

The relationship between soluble iron and colloids in certain residual clays. G. R. MACCARTHY. *Soil Science* 20, 473-5(1925).—A fair correlation was observed between the colloid content of 4 highly weathered soils as detd. by the ratio method and the content of Fe sol. in dil. HCl. Discordant results were obtained with 2 soils contg. large amts. of undecomposed mineral grains. The wide variation in the SiO₂:(Al₂O₃ + Fe₂O₃) ratio in soil colloids was not taken into consideration.

R. BRADFIELD

The influence of hydration on the stability of colloidal solutions of soils. L. C. WHEETING. *Soil Science* 20, 363-6(1925).—The relative hydration of different soil colloids in contact with different salt treatments was estd. by measuring 2 cc. of a concd. colloid sludge + 1 cc. of the salt treatments into a dilatometer and measuring the expansion on freezing at -4°. The values obtained with the check indicated the presence of from 3.11 to 3.40 cc. of free H₂O although only 2 cc. of sludge and 1 cc. of H₂O were added. The extra vol. is considered due to the liberation of water of hydration by the freezing process. The use of 1 cc. of 0.2 N Na₂CO₃ decreased the amt.

of H_2O liberated while the same quantities of $\text{Pb}(\text{NO}_3)_2$ and $\text{Al}_2(\text{SO}_4)_3$ increased it slightly. Flocculation resulted with the two latter salts and peptization with the Na_2CO_3 . W. concludes, therefore, that the stability of soil colloids is governed by the quantity of H_2O of hydration held by the particles. The elec. charge on the particle is not considered.

R. BRADFIELD

The influence of the amount and nature of the replaceable base upon the heat of wetting of soils and soil colloids. W. W. PATE. *Soil Science* 20, 329-35(1925).—Soils were satd. with different bases by leaching with normal solns. of the chlorides and the heats of wetting detd. after the excess Cl was leached out and the soil dried at 110° . In every case the soils satd. with univalent bases gave lower values than those satd. with bivalent bases. With extd. colloids values ranging from 6.50 to 10.24 cal. per g. were obtained with the NH_4 -satd. series and 7.72-14.40 cal. per g. for the Ca-satd. series. Untreated soils in general were very similar to the soils satd. with bivalent bases. A fair correlation was found between heat of wetting, exchangeable-base content, and colloid content detd. by the ratio method. Variations in heat of wetting and replaceable-base content in different soils were correlated with the $\text{SiO}_2:(\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3)$ ratio; soils having the higher ratio of SiO_2 in their colloidal complex, have in general, higher content of replaceable bases and give a greater heat of wetting.

R. BRADFIELD

Two unusual colloidal soils. C. F. SHAW. *Soil Science* 20, 419-23(1925).—Two colloidal soils, one from the island of Hawaii, the other from the recently exposed bed of Lower Klamath Lake on the Cal.-Ore. line, are described. Both are gelatinous when wet and horny when dry. The H_2O content under field conditions is 133-540% without seepage. H_2O equiv. 348-380% vol. wt. of field soils (wet basis) 1.105; dry soil floats on H_2O ; loss on ignition 31-54%. The Klamath Lake soil has the following compn.: SiO_2 39.89, Al_2O_3 4.66, Fe_2O_3 1.23, SO_4 0.67, Ca 3.00, Mg 0.62, K 0.33, Na 0.62 and volatile matter 47.41%. The Hawaiian soil is formed by residual weathering of basic lavas under high temp. and rainfall. Crop growth is poor. The Klamath soil is composed largely of remains of diatoms. It has only recently been exposed and is wholly unaltered by weathering. Its agricultural value is probably very low.

R. BRADFIELD

A critical p_{H} for the formation of hardpan in acid clay soils. J. R. SKREEN. *Soil Science* 20, 307-11(1925).—A correlation was found between the p_{H} value of the soil and the occurrence of hardpan. This critical value was on the av. about 4.8. The cementation in these pans was due largely to pptd. Fe and Al. The low p_{H} values in the region studied are probably due to the leaching of the soils with the SO_2 produced in large quantities in the industrial section of Philadelphia. Some expts. on synthetic pans made in the lab. are described.

R. BRADFIELD

Nitrate accumulation under the straw mulch. W. A. ALBRECHT AND R. E. UHLAND. *Soil Science* 20, 253-67(1925); cf. C. A. 17, 2339.— NH_3 was found in greater quantities in the mulched plots. Aerating the mulched soil increased nitrate accumulation. The mulch increased the H_2O content of the soil and caused a marked change in soil structure. When used as inoculum the soil from the mulched plots was inferior to the check for converting NH_3 to NO_3 . Removal of the mulch gave a marked increase in nitrates after 2 mos. The ill effects seem to be due to a retardation of the evaporation rate which results in a higher H_2O content, lower temp. and prevents normal aeration.

R. BRADFIELD

Relation of biological processes to cation concentration in soils. J. S. BURD. *Soil Science* 20, 269-83(1925).—Analyses were made of the compn. of the soil soln obtained by the displacement method after various treatments. Some samples were displaced continuously, others were subjected to different temps., degrees of aeration, etc., after the first displacement then subjected to as many as four successive displacements at different time intervals. Under biol. oxidizing conditions nitrates increased, bicarbonates decreased and cations in general increased slightly in concn. The reverse was true under biol. reducing conditions; nitrates almost disappeared, bicarbonates increased markedly and the concn. of most cations decreased slightly. The variations in cation concn. were not as great as in the case of the different anions, because of the reciprocal relation between NO_3 and HCO_3 and SO_4 . The results emphasize the importance of biol. over direct soln. processes in the soil soln.

R. B.

The hydrogen-ion concentration of soils as affected by carbonic acid and the soil-water ratio, and the nature of soil acidity as revealed by these studies. W. H. PIERRE. *Soil Science* 20, 285-305(1925).—The colorimetric method of detg. the p_{H} value was found to be more reliable than the H-electrode for the very slightly buffered H_2O exts. of soils and of displaced soil solns. In order to obtain reliable results with the colori-

metric method it was necessary to use very clear exts. The filtration method, with the colloidal clay as an ultrafilter, developed by Truog was most satisfactory. With the soils studied, filtered exts., soil suspensions, and displaced solns. gave the same H-ion concn. Bubbling CO_2 through a soil suspension increased its acidity as measured with the H-electrode. Growing crops had no appreciable effect on the p_{H} value of the displaced solns. of the soils in which they were growing. The passage of CO_2 through a soil column had no detectable effect upon the soln. displaced immediately after the treatment. The p_{H} value of the ext. of some soils changed with the soil- H_2O ratio used. If the sol. salts and acids were removed by washing, the exts. yielded the same p_{H} value regardless of the soil- H_2O ratio. In this study the p_{H} value of the washed soil was not detd.

R. BRADFELD

Base exchange in relation to alkali soils. W. P. KELLY AND S. M. BROWN. *Soil Science* 20, 477-95(1925).—A careful study was made of all the more important types of alkali soils found in the U. S. They fall into 3 classes: (1) Soils whose replaceable Ca and Mg have been substituted mainly by Na. Such soils have a high content of H_2O -sol. Na salts, but little Ca and Mg and become extremely impermeable on leaching out the sol. salts. (2) Soils in which the substitution of Na has taken place to but a limited extent. They may contain considerable sol. Na but also contain Ca. They are less impervious than those in group (1). (3) Soils low in replaceable Na and high in Ca and Mg salts. Na salts may be fairly high but in the presence of large amts. of Ca and Mg they do not enter the exchange complex. These soils do not become impermeable on leaching out the Na salts. In the practical reclamation of these soils group (1) will require special treatment in large amts., preferably Ca salts. Group (2) may be benefited by such special treatments but the application need not be so large. Group (3) may be improved by mere flooding and drainage. The ultimate objective in alkali soil reclamation is to restore the normal proportion of replaceable Ca in addn. to the removal of the sol. salts. Elemental S is a promising treatment for soils contg. large amts. of CaCO_3 . All treatments will give only temporary improvement unless the H_2O table is kept low enough to prevent the rise of sol. salts by capillarity. The results reported are in complete accord with the findings of European workers.

R. BRADFELD

The soils of the experimental fields in Dolgoprudnoe. N. REMESOV. *Trans. Inst. Fertiliz. (Russian)* 1925, No. 30, 8-46.—A detailed description of the relief, geology, rocks of the region, the morphology of the soil, topography, physical and chem. properties of the soil, with a complete description of methods used in analyzing the various fractions.

J. S. JOFFE

Soil survey of Nyasaland. A. J. W. HORNBY. *Nyasaland Dept. Agr. Bull.* 2, 4 pp.(1924); *Expt. Sta. Record* 53, 115.—Data on the mech. and chem. compn. and the fertility requirements of the prevailing soil types of Nyasaland are briefly presented and discussed.

H. G.

Suction force of soils: A note on the application of this principle in the study of the soil-plant system. J. S. JOFFE AND H. C. MCLEAN. *Science* 62, 548-50(1925).—Besides serving as an index of the colloidal content of soils, the suction force principle has several other applications. It is the force which must be overcome by plants in imbibing water, when the water concn. is below satn., and it reaches a critical pt. at about half satn. Thus it may be linked with the wilting pt. of plants. The equil. between the suction force and the pulling power of the plant will be shifted by factors such as low or high evapn. intensity, reducing the problem to a study of these 2 factors. Another application is in the study of the moisture movement in soil profiles, involving the suction force of layers. The principle may further be utilized in irrigation problems.

P. R. DAWSON

The rate of oxidation of different forms of elemental sulfur. R. H. SIMON AND C. J. SCHOLLENBERGER. *Soil Science* 20, 443-9(1925).—Four commercial forms of elemental S were incorporated in the Wooster silt loam at the rate of 500 lb. per acre and the changes in p_{H} value and SO_4 content detd. at intervals for 8 wks. The rate of oxidation was influenced more by the fineness of grinding than any other factor. With one exception the oxidation process continued throughout the test period and at the end of 8 wks. 187-465 lb. of the added S had been oxidized. The original soil was about neutral and the lowest p_{H} value obtained during the expt. was only 6.1. A close correlation existed between the amt. of S oxidized and the lowering of the p_{H} value.

R. BRADFELD

The action of an application of lime on clay soils. D. J. HISSINC. *Onderdruk uit het Landbouwkundig. Tijdschr., Maandblad van het Nederl. Genootschap. voor Landbouwwetenschap.* 37, No. 442, 443, 444, 20 pp. (1925).—Limed heavy clay soils were

richer in CaCO_3 than the unlimed ones. They also showed a higher content of exchangeable Ca in the clay-humus portion. The excess of lime in 3 limed soils was correlated with the application of lime made. The percentages of exchangeable CaO in the clay and in the humus are estd. The max. value for the clay of Netherlands soils was found to be 1.1 and for the humus 5.2. There is a correlation between the p_H and the exchangeable Ca value of humus. It is assumed that the CaO combines with the humus at a definite p_H and that by difference the amt. combined with the clay may be obtained. With these values and the highest exchange values observed in humus and clay, the amt. of CaO with which the soils are able to combine is calcd. The term "efficiency coeff." is used to express the percentage difference between the actual amt. of CaO fixed and the calcd. amt. which the clay and humus are capable of fixing. Factors found to control this "efficiency coeff" are (a) the satn. of the clay-humus substances in bases, (b) the excess of CaO applied, and (c) the mixing of the CaO with the soil, the duration of the action, and the condition (finess, etc.) of the liming material.

R. M. BARNETTE

The results of the investigation of several clay soils from the province of Groningen (Netherlands). D. J. HISSINK AND J. VAN DER SPEK. *Overdruk uit het Groningen Landbouwwblad* 1925, Dec. 12 and 19, 16 pp.—Several samples of heavy clay soils from the province of Groningen were analyzed for CaCO_3 , humus, clay, exchangeable CaO, p_H and P_2O_5 . From the calcn. of the values for exchangeable CaO in the clay and the humus of these soils, it is concluded that most of the soils are capable of fixing more CaO. The quantity of CaO which the soils may fix to reach max. exchange values is calcd. (cf. preceding abstract). The influence of the CaO on the structure of the heavy clay soils is emphasized. The form of CaO best suited to improving a bad phys. condition is discussed. $\text{Ca}(\text{OH})_2$ is given preference over the less sol. forms.

R. M. BARNETTE

The action of an application of lime on a "roodoorn" soil. D. J. HISSINK. *Overdruk uit het Landbouwkund. Tijdschr. Maandblad. van het Nederl. Genootschap voor Landbouwwetenschap*. 37, No. 445, 392-8 (1925).—"Roodoorn" soils are unsatd. strongly acid clay soils contg. large percentages of humus. Samples taken of a soil limed with 20,000 kg. per ha. of beet residue contg. 53% CaCO_3 and an unlimed portion of the same field were investigated as to reaction (p_H), humus content, clay content, sand content, exchangeable CaO, P_2O_5 , and N. The lime was found to be completely fixed by the clay and humus, there being no CaCO_3 in the limed sample. The clay-humus-substances of the unlimed soil were found to be unsatd. with respect to lime and to have low Ca exchange values. After liming the exchangeable Ca values for humus and clay were higher. The additional amt. of CaO with which the clay-humus substances could combine over that which they contained was calcd. by using as a basis the highest Ca exchange values which have been encountered in Netherlands soils (cf. 2nd abstract above). The soils were found to be well supplied with P_2O_5 and with org. N. The adequacy of this common application of lime is questioned because of the unsatd. condition of the soil after liming.

R. M. BARNETTE

Liming and soil nitrates. N. REMESOV. *Trans. Inst. Fertilizers (Russia)* 1925, No. 30, 105-18.—This is a study of the influence of liming on nitrate formation and accumulation in soils. The results were conflicting and no conclusions could be drawn.

J. S. JOFFE

Influence of lime on the decomposition of organic matter in soils. A. F. TYULIN. *Trans. Inst. Fertilizers (Russia)* 1923, No. 14, 3-12.—Lime applications tend to speed up the decompn. of the org. matter. Together with the decrease in the org. matter goes on a quant. regrouping of the kinds of humus substances; the fraction which is subject to high dispersion, the so-called crenates and apocrenates, is increased, the stable humus is decreased.

J. S. JOFFE

The injurious effect of excessive lime applications. A. F. TYULIN. *Trans. Inst. Fertilizers (Russia)* 1923, No. 18, 3-15.—Excessive liming brings about an alk. reaction, an increased amt. of sol. Ca salts and as a result nitrites appear and at times NH_3 in the early stages. Either factor by itself is not of great importance in soil reactions, but the disturbance in nitrification and activation of denitrifiers is important.

J. S. JOFFE

The disintegration of limestone and dolomite separates as influenced by zone of incorporation. W. H. MACINTIRE AND W. M. SHAW. *Soil Science* 20, 403-17 (1925). An analysis is presented of data obtained in a 4-yr. lysimeter study on: (1) the effect of fineness of grinding and (2) the zone of incorporation, upon the rate of disintegration of limestone and dolomite in a Cumberland loam soil having an initial p_H value of 6.38. Four separates, 10-20, 20-40, 40-80, and 80-200-mesh, resp., of both limestone and

dolomite were thoroughly incorporated with the surface soil subsoil in a second series and the degrees of disintegration after an analysis of the soil for residual carbonates.

Liming and phosphate applications on the experiment of Krukovo and Volokolamsk. S. SHCHERBA. *Trans. Inst. Fertilizers* (Russian), 1925, 85.—On heavy soils liming has only a slight influence on oats but the effects on clover and vetch were good. There is a discussion of the relative amounts of CaCO_3 to be used.

Some residual effects on neutral salt treatments on the soil reaction. C. H. SPURWAY AND R. H. AUSTIN. *Soil Science* 21, 71-4 (1926).—Samples of soil from the 1, 1₁, A₂, B and C horizons of 4 soils were treated with 2 N neutral solns. of CaCl_2 , MgCl_2 , KCl and NaCl and after frequent stirring for 1 hr. the samples were thrown on a filter and washed with H_2O until chlorides were removed. The pH value of the residual soil was then detd. electrometrically. The reaction of the soil was not appreciably changed by the CaCl_2 treatment, a slight increase in pH value was obtained with MgCl_2 and a marked increase with both KCl and NaCl.

Effect of the concentration of potassium salts in soil media upon the carbohydrate metabolism of plants. The diastatic activity of the nasturtium. D. T. ENGLIS AND H. A. LUNT. *Soil Science* 20, 459-63 (1925).—Nasturtium plants were grown in the greenhouse in pots of sand and peat treated with different amts. of KCl. The plants were harvested at the appearance of the first bloom, dried at 45-50° for 5 days, weighed, then ground fine and stored for analysis. The diastatic activity was detd. by a modification of the method of Brown and Morris. The activity decreased with increase in K in the case of sand. With peat it increased with small applications but decreased with the higher concns. The results suggest a correlation of diastatic activity with favorable growing conditions rather than with the presence or absence of K. The lowest application of KCl to sand was 49 lbs. per acre, the peat received none.

Action exercised by alkali chlorides on plants and soils. C. DUPONT. *Ann. Sci. agron.* 41 (1924); *Expt. Sta. Record* 53, 21.—Lab. studies of the action of the chlorides of Na and Ca on wheat, flax, vetch, buckwheat, white lupines and mustard on siliceous soil well supplied with org. matter are reported, the purpose being to det. the conditions governing the best use of these chlorides as fertilizers. A comparison was also made of the carbonate and the chloride of K on buckwheat in garden soil. The results showed that the addn. of chlorides to the soil increased the Cl content of the crops, but this increase varied widely with different crops and there was no relation between the quantity of Cl absorbed and its toxic action. When used on soils well supplied with alkalis, alk. chlorides tended to decrease the alky. of the sol. part of crop ashes, but where the soils were deficient in potash, resulting in a reduced alky. of the crop ashes, the use of KCl increased in the alky. of the sol. ashes. Studies of the influence of chlorides on the soil showed that the transformation of KCl into CaCl_2 in soil depended upon the absorbing power of the soil. It was almost complete in clay soils, but was feeble in siliceous soils deficient in colloidal elements. NaCl underwent such transformation to a less extent than KCl indicating that the power of soils to absorb Na is less than that for K. Dissolved lime salts had little action on the absorption of potash. On the contrary, they retarded the absorption of Na and consequently decreased the formation of CaCl_2 at the expense of NaCl. When NaCl and KCl were applied to soil, as when sylvinit was used, the CaCl_2 formed at the expense of the KCl prevented the transformation of the NaCl and decreased lime losses.

H. G.

Alkali studies. III. Tolerance of barley for alkali in Idaho soil. R. E. NEDRIG AND H. P. MAGNUSON. *Soil Science* 20, 367-91 (1925), cf. *C. A.* 19, 2100.—Four crops of barley were grown on Idaho soil treated with various concns. of Na_2CO_3 , NaCl and Na_2SO_4 and 2 and 3 salt combinations of these salts. In general the first crop was injured most. The majority of the treatments increased the second crop of barley. The 4th crop approached the normal in yield. NaCl when present in a combination that did not exceed the toxic limit produced the greatest stimulation in yield. The toxicity of Na_2SO_4 did not become very acute until very high concns. over 15% were used. The results differ widely from studies reported on other soils and indicate the necessity of considering the alkali tolerance of the soil as well as that of the crop. **IV. Tolerance of oats for alkali in Idaho soil.** *Ibid* 425-41.—In a series of pot studies similar to the above except oats were grown instead of barley. The general response of the two crops was similar. 0.4% added Na_2CO_3 which gave 0.15% recoverable carbonates was toxic, NaCl was toxic in concns. of 0.2-0.3% added salt or 0.17-0.20% recoverable salt. Na_2SO_4 in concns. as high as 1.5 was toxic only to the first crop. Low addns.

of NaCl and Na₂SO₄ to a basic treatment of 0.2-0.4% Na₂CO₃ usually increased the yields over the single basic treatment indicating some sort of ion antagonism. R. B.

Potassium ferrocyanide and ferric ferrocyanide as sources of iron for plants. C. G. DEUBER. *Soil Science* 21, 23-6(1926).—Soy beans and *Spirodela polyrrhiza* made fair growth in solns. contg. 0.033-0.066 p. p. m. of Fe in the form of K₄Fe(CN)₆. Higher concns. proved toxic. Merck's Fe₄(Fe(CN)₆)₃ was a satisfactory source of Fe for soy-bean plants when the soln. had a reaction of p_H 5.0. When used in a series of buffer mixts. this salt gave min. growth at p_H 6.4. This reaction corresponds to the isoelec. point of the soy-bean root tips as detd. by Robbins and Scott. R. B.

May Chile saltpeter be replaced by other nitrogenous fertilizers? A. BIEDERBECK. *Z. Zuckerind. czechoslov. Rep.* 50, 177-81(1925).—Reply to Stoklasa, C. *A.* 20, 258. There is no evidence that the I content of Chile saltpeter has a favorable influence on the growth of beets, and that it may be replaced by an equiv. amt. of any nitrogenous fertilizer. W. L. BADGER

Comparative study of the "six types" of nutrient solutions in relation to the growth of potato plants in sand cultures. F. S. JOHNSON. *Soil Science* 20, 397-401(1925); cf. *C. A.* 19, 2721.—The av. relative dry wt. of Irish Cobbler potatoes, grown in sand cultures with the "6 types" of salt combinations recommended by the Div. of Biol. and Agr. of the Natl. Research Council were: 1.23, 1.18, 0.92, 0.84, 0.95, 0.88 for types I-IV, resp. Best growth was associated with the high N content of the solns. except when it was supplied as Mg(NO₃)₂, the high concn. of Mg apparently being toxic. Ca(NO₃)₂ was the best carrier of N. The superiority of I over II is attributed to its more favorable reaction; p_H 4.6 as compared with 3.7. R. BRADFELD

Residual effects of forty years' continuous fertilizer treatments. II. Effect of caustic lime on soil treated with barnyard manure. J. W. WHITE AND F. J. HOLBEN. *Soil Science* 20, 313-27(1925); cf. *C. A.* 19, 1469.—An analysis is made of plots which had received 120 tons manure in 40 yrs. with and without applications of CaO, 2 tons every 4 yrs., total 20 tons. The manure + lime plots produced 13,120 lbs. more dry matter than manure alone. At the end of 40 yrs. the CaO + manure soil contained 64,179 lbs. org. matter and 3168 lbs. N per acre compared to 63,374 and 2990 lbs., resp., in the unlimed manure series. Lime stimulated azofication, 294 lbs. more N being fixed. 90% of the manure added was decomposed on the limed and 84% on the unlimed plots. It is estd. that 93% of the org. matter of the limed and 88% of the unlimed has been derived from crop residues. Lime applied to the manured soil stimulated the decay of 2900 lbs. of org. matter in excess of the manure without lime, but crops were increased sufficiently to cause an accumulation of 4245 lbs. of crop residues, resulting in a net balance of 1345 lbs. org. matter in favor of the limed plot. Liming decreased the amt. of alkali-sol. humus. The N:C ratio of the sol. humus was approx. the same as for the soil as a whole. The amt. of humus extd. with alkali depended upon length of the extn. period. The org. C or N content of a soil is considered a better index to fertility than the alk. humus method. R. BRADFELD

The assimilation of peat nitrogen by plants. P. COOPREENOK. *Trans. Inst. Fertilizers (Russia)* 1923, No. 19, 1-19.—A series of expts. with various kinds of peat as a source of N in the soil has shown that moss peat has increased the yield 178%; swamp meadow peat increased it 56% and transition-state swamp peat increased it 14%. Addition of lime greatly increased efficiency of peat as a N source. Inoculation with animal manure, especially urine, stimulates utilization of N. The use of peat has also increased the % of N in crop. J. S. JOFFE

The value of the organic nitrogen of koufri, marog and tafla. V. N. MOSSÉRI. *Bull. inst. Egypte* 6, 1-8(1924).—Expts. demonstrated that a considerable fraction of the org. N of koufri is assimilable. In 1.5 mos. 4-11% is nitrified and in 2 mos. 8-21%. The process is more or less slow, depending upon a no. of factors, such as the nature of the org. matter, that of the soil and its reaction, the quantity of koufri applied, duration of plant growth, climatic conditions, etc. Likewise the quantity, nature and proportion of the sol. salts of the soil or the koufri play an important role. Compared with dried blood under identical conditions, the org. N of koufri may be assigned a value of 5-10% that of the N of NaNO₃. Tafla and marog contain in general insignificant concns. of such assimilable N. P. R. DAWSON

Effects of various methods of applying fertilizers on crops and on certain soil conditions. D. G. COE. *Soil Science* 21, 7-21(1926).—A thorough study was made of the effect of the method of applying different fertilizers in various amts. upon the germination, top growth and root development of crops and upon the movement of the fertilizers. Phosphatic fertilizers were the least toxic to plants but when applied in direct contact with the seed even it was toxic when used at the rate of 300 lbs. per acre. NaNO₃

and KCl at the rate of 25 lbs. per acre retarded germination. Placing the fertilizer 1 inch to the side of the row of seed gave better returns than applications a similar distance above or below the seed because of the fact that the lateral diffusion of salts is much slower than the vertical diffusion. The side application is recommended for all localized fertilizer treatments.

R. BRADFIELD

The availability of nitrogen in garbage tankage and in urea in comparison with standard materials. A. L. PRINCE AND H. W. WINSOR. *Soil Science* 21, 59-69 (1926).—Vegetative expts. with barley, rape and sorghum in sand cultures gave the following relative availabilities for different N carriers based on NaNO_3 as 100%: Urea 98%, $(\text{NH}_4)_2\text{SO}_4$ 88.2%, standard tankage 53.4%, fish 49.2%, and garbage tankage 14.2%. The chief value of garbage tankage is probably for a fertilizer filler. Urea was a very desirable source of N, in a few cases superior to NaNO_3 and in every case superior to $(\text{NH}_4)_2\text{SO}_4$. Chem. availability tests by 3 methods failed to correlate except in a very general way with the vegetative expts. The rates of decompn. of urea in sand, $1/2$ sand + $1/2$ soil, and soil in 5 days were 3, 67 and 90% resp. In the soil 50% of the urea was converted into NH_3 in 3 days. Eleven days was required for 50% decompn. in the case of an acid soil. This rate was raised by CaCO_3 applications.

R. B.

The new artificial manure. F. M. LAWRENCE. *Canning Age* 1926, 129.—In making manure artificially, a substitute for animal matter, such as vegetable wastes, roughages of various kinds, corn stover, pea vines, dried leaves, wild grasses, ferns, sugar-cane wastes, banana leaves (almost any kind of non-woody vegetable material), is worked by a special process into a matter acceptable to the growth of certain bacteria.

T. MARKOVITS

Fertilizer trade developments. OTTO WILSON. *Ind. Eng. Chem.* 18, 401-4 (1926).

E. J. C.

Experiments with sulgin. A. F. TRAAEN. *Meldinger Norges Landbrukshoeiskole* 4, 194-200 (1924).—Sulgin is a soil disinfectant, for which stimulating action on the N fixation and the growth of plants has been claimed. The chief constituents are CaS about 30%, lime 50%, bone meal 10% or less and some K_2O . It was studied in regard to its influence upon the microbiological activities in 3 different soils, clay, silt and compost. In no case did sulgin show any power of stimulating the N fixation of the soils. Sulgin appeared to check the intensity of nitrification more or less, according to the nature of the soil.

C. A. ROBARK

Restoring the strength of mercurial solutions employed for treating grain. J. KRAUSS. *Z. angew. Chem.* 38, 1088-91 (1925).—German governmental publications direct that Hg-contg. preps. that have been used for treating grain are to be brought up to strength by adding a "new soln. whose concn. is twice as great as the prescribed soln." By studying the Hg content of spent solns. and the Hg absorbed by treated grain, it was found that the time of treatment had a great influence upon the amt. of Hg taken up, but that in general the above directions are satisfactory.

W. C. E.

Composition and action of cupric sprays. G. VILLEDIEU AND MME. VILLEDIEU. *Rev. vit.* 64, 67-70 (1926).—Good protection, equal in all respects to Bordeaux mixt., was obtained in collaborative field expts. with a spray of the following compn.: 3 kg. of a sulfate mixt., consisting of 10-20% CuSO_4 , 10-20% MgSO_4 and 80-60% 200-mesh hydrated CaSO_4 ; 3 kg of quicklime; and 1 hectoliter of water.

Irrigation as a factor in modifying the composition of grain (GREAVES) 12.

Fertilizer. H. SANDERSON. U. S. 1,571,970, Feb. 9. Comminuted shells of cacao beans are used as a fertilizer ingredient together with dried humus, sand, lime, loam or other materials.

Fertilizer. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 42,237, Dec. 21, 1925. The mixed crystals of K Al nitrate obtained from a potash-contg. Al nitrate liquor are mixed with a raw material the plant nutrients of which are converted in an assimilable form by the acid of the Al nitrate.

"Attractant" for insects. L. B. SMITH, E. A. RICHMOND AND P. A. VAN DER MEULEN. U. S. 1,572,568, Feb. 9. Geraniol is used for attracting the Japanese beetle or other insects and may be incorporated with inert material and insecticides.

Insecticide and fungicide. N. A. ALEXANDERSON. Swed. 60,110, Jan. 12, 1926. An aq. soln. of Ca cresolate is especially fit for killing the flea-beetle on root plants.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The separation of the enzymes of malt. W. WINDISCH. *Wochschr. Brau.* **43**, 18-20(1926); cf. Pringsheim, Genin and Perewasky (*C. A.* **20**, 924).—In addn. to diastase malt contains 2 other polyases: lichenase which forms cellobiase from lichenase, and mannanase which converts mannanase to mannobiose. Malt also contains 2 disaccharases, cellobiase and mannobiose, and sometimes a maltase. After 18 days at p_H 3-4 mannanase and cellobiase were inactive, and amylase was slightly active. At p_H 6-7 all enzymes were more resistant. At p_H 3 in the presence of kaolin adsorption of enzymes was almost quant. At p_H 5 medium adsorption occurred, and at p_H 8 and by the addn. of alc. the mannobiose and part of the cellobiase were adsorbed, whereas the mannanase and lichenase remained in soln. $Al(OH)_3$ gave similar results. By repeated treatment with phosphate buffers at varying p_H the amylase remained in the filtrate mixed with maltase. By decreasing the kaolin and by washing with increasing amts. of alc., the 2 enzymes were sepd. Maltase and amylase can be sepd. not only from each other but from reducing substances found in the presence of malt enzymes.

C. N. FREY

A rare nectar yeast. J. GRÜSS. *Wochschr. Brau.* **43**, 57-61(1926).—This yeast, named *Amphiernia rubra*, produces no CO_2 or alc. It forms glycogen and fat from glucose. No fat is formed if S is added and the H_2 removed as H_2S . The H_2 is probably formed from glucose: $C_6H_{12}O_6 + 2O \rightarrow COOH(CHOH)_4COOH + H_2$. The O is probably derived from $3C_6H_{12}O_6 \rightarrow C_{18}H_{34}O_2 + H_2O + 15O$. The O attacks more sugar: $7C_6H_{12}O_6 + 14O \rightarrow 7COOH(CHOH)_4COOH + 14H$, $3C_6H_{12}O_6 + 12H \rightarrow 6C_3H_8O_3$. An oxidase is present in active cells and can be demonstrated by the use of violamin soln. Reductase is also present in the cells.

C. N. FREY

Vertical driers. PETER HETZEL. *Wochschr. Brau.* **43**, 61-6(1926).—The relative merits of vertical and horizontal driers are discussed. Expts. are given showing the results obtained by the use of vertical driers in drying malt.

C. N. FREY

Reaction of the mashing liquor in relation to extract yield and soluble non-coagulable nitrogen. A. C. CHAPMAN AND C. W. MCHUGO. *J. Inst. Brewing* **31**, 306-11(1925).—Exptl. mashers were made with samples of malt of diastatic power ranging from 21° to 150° Lintner, with mashing liquors of varying H-ion concns. With distd. water, p_H 5.0 and with London supply water acidified with lactic acid to p_H 4.2 and 3.4, the differences of ext. yield were very small, and only a slight increase of non-coagulable N was obtained with increasing H-ion concns. The H-ion concns. of the worts were lower than those of the corresponding mashing liquors by about p_H 1.0 with the more acid liquor and about p_H 0.6 with distd. water. Mashers made with London well water, p_H 7.9, and London supply water, p_H 7.8, gave an ext. yield of about 2 lbs. per quarter lower than with distd. water and also a smaller percentage of non-coagulable N. The H-ion concns. of the worts of the alk. mashers were increased to about p_H 6.3-6.6.

B. C. A

Hypocras. J. PRITZKER AND R. JUNGKUNZ. *Schweiz. Apoth. Ztg.* **63**, 361-1, 380-4(1925); cf. *C. A.* **19**, 2257.—Further historical notes by correspondents. S. W.

Temperature conditions of the vinegar generator and their influence on production. FR. SCHRANK. *Deut. Essigind.* **30**, 61-2(1926).—A discussion of the factors involved.

W. O. E

Yeast. R. L. CORBY and RUTH GLASGOW. U. S. 1,571,932, Feb. 9. A yeast nutrient soln. is prepd. consisting essentially of molasses, cereal material and yeast nourishing salts and in which an acidity is produced somewhat in excess of that preferable for yeast propagation. The acidity is then properly reduced and the amt. of assimilable N for yeast growth in the soln. raised by the addn. of an alk. compl. contg. yeast-assimilable N, e. g., NH_4OH .

Apparatus for separating yeast from associated liquid in vats. W. SCOTT. Brit 242,114, Jan. 5, 1925.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

How varied conditions affect some essential oils. R. A. KONNERTH. *Am. Perfumer* 20, 695(1926).—In an effort to det. to what extent the factors of temp. variation, exposure to light, air or oxidation, contact with container, etc., might be responsible for deterioration, a series of expts. was conducted on anise, lemon, lemon (terpeneless), orange, peppermint and eugenol oils with the following results: the oils examd. undergo the least deterioration if stored in bottles under N. Keeping the oil in tins at room temp. causes rapid deterioration in odor and darkening in color. At low temp. the development of a darker color and impairment of odor are somewhat retarded. Lemon oil keeps fairly well in tins if under N. The terpeneless product retains its fragrance, though darkening in color to a deep yellow, if stored in amber glass bottles under N. Oxidation and exposure to diffused daylight cause a dark orange-yellow color and a very disagreeable odor. No complete data are available on tin-can storage, since these were lost after 6 months' observation. Indications were, however, to the effect that this oil does keep fairly well in tins. Orange oil keeps better at room temp. than in the refrigerator. It also keeps fairly well in tins under N. Light hastens the darkening of color. Peppermint oil is more stable than the other oils, but is subject to a decided color change when in contact with tin. Protection from light retards the development of color and impairment of odor. Eugenol is rapidly affected by oxidation, passing from colorless to dark reddish orange. Storage in tins causes rapid deterioration in both odor and color. Reduced temp. retards the development of color.

W. O. E.

Medicaments derived from saccharin and its secondary products. WALTHER HERZOG. *Pharm. Zentralhalle* 67, 81-6(1926).—An enumeration and discussion of certain Au and Hg compds. of saccharin, and derivs. of *p*-toluenesulfonic acid and *p*-aminobenzoic acid used medicinally.

W. O. E.

Scientific pharmacy. RAPP. *Pharm. Ztg.* 71, 88-90, 214-7(1926). I. **Decoctions and infusions.** II. **Pills.**—A plea backed by exptl. data for a return to the earlier methods for prep. decoctions and infusions and pills in the apothecary, instead of having recourse to com. brands of possibly questionable potency.

W. O. E.

Determining the effectiveness of trade disinfectants. H. IJERS AND FRANZ WEINFURTER. *Wochschr. Brau.* 43, 25-9, 35-9, 45-9(1926).—The following disinfectants were tried out experimentally and their phenol coeffs. detd.: antiformin, chloramine, pantosept, "Magnocid," CaOCl_2 , SO_2 , H_2SiF_6 , NH_4F , $\text{CH}_3\text{OHHSO}_3$, HClHO , $\text{C}_6\text{H}_5\text{OH}$, HCOOH , $\text{C}_6\text{H}_5\text{COOH}$, Cl , HgCl_2 , cyclotelluridimethylpentane, $\text{C}_6\text{H}_4\text{OIHCOOH}$ and "Pyritzit" (BF_3Na).

C. N. FREY

Studies in the genus *Mentha*. VIII. **The aldehydes of peppermint oil.** R. E. KREMERS. *Am. J. Pharm.* 98, 86-91(1926); cf. *C. A.* 20, 92.—The aldehydes and reactive ketones have been isolated from a large quantity of crude peppermint oil. The aldehydes obtained had the phys. characters of the aliphatic series and the predominating fractions were within the distg. range of the valeric group. 3-Methylbutanal (isovaleraldehyde) was quantitatively the most important constituent and was definitely identified through conversion into isoleucine. The presence of a *d*-2-methyl-2-butanal, suggested by the optical activity of the valeric fractions, was not confirmed. No compd. was identified in the high-boiling fractions.

W. G. GAESSLER

Solution of magnesium citrate U. S. P. X. J. W. ENGLAND. *Am. J. Pharm.* 98, 91-4(1926).—The formula of the U. S. P. IX is too acid to be palatable (*C. A.* 18, 3449); that of the U. S. P. X is even more acid. The increased acidity has been made to insure greater stability and prevent pptn. but it is secured at the expense of acceptability. The soln. of the problem is in a return to the official formula of 1870 of 13 g. carbonate and 26 g. of acid, or rounded off, metrically 12.5 g. of the former and 25 g. of the latter. If a wholly acid-salt soln. be found necessary it could be had by adding more acid, but even with this, the acidity would be much less than that of the present soln. The U. S. P. for many years required the use of KHCO_3 only. In the new revision (as in the U. S. P. IX) either KHCO_3 or NaHCO_3 is permitted. It is not generally recognized that a part—and it is no small part—of the therapeutic value of soln. of Mg citrate is due to the diuretic and diaphoretic action of its alkali citrate—that elimination is to be secured not only by purgation, but also by diuresis and diaphoresis. Therapeutically the use of KHCO_3 for carbonating soln. of Mg citrate is indicated, not NaHCO_3 , and charging the soln. with CO_2 as a substitute for the alkali

bicarbonate is to be condemned because CO_2 does not have the therapeutic properties of the alkali citrate.

Second international conference on the unification of formulas of heroic remedies. *Am. J. Pharm.* **98**, 94-108(1926).—General recommendations as to nomenclature and methods of standardization are discussed. Cooperation with the Committee on Hygiene of the League of Nations is recommended.

The presence of sugar in saliva. HELEN UPDEGRAFF. *Dental Cosmos* **68**, 237-9 (1926).—"While the elimination of sugar in the saliva is a rare phenomenon, even in cases of severe diabetes, nevertheless it may occur in some advanced cases." In 68 samples of human saliva from normal individuals, the presence of sugar could not be detected, sugar was also absent from the saliva of 3 normal individuals 1 hr. after ingestion of from 100 to 300 g. of dextrose. A bibliography is appended. J. S. H.

Tutocaine in dentistry: a new anesthetic. BORIS LEVITT. *Dental Cosmos* **68**, 240-1(1926).—Tutocaine has value as a local anesthetic for conduction anesthesia.

Gordin's method for the determination of alkaloids. H. M. FERREIRA. *Arch. med. legal* **1**, 325-6(1925).—Gordin's method (titration with HCl and phenolphthalein) gave exact results for most alkaloids including colchicine. Berberine, meconine, cantharidine and narceine did not dissolve in 0.05 N HCl even after 24 hrs. contact. Results obtained with Mayer's and Bouchardot's reagents are given.

Determination of filicin in the ether extract of male fern. ELISA MOSSO. *Gior. farm. chim.* **75**, 8-13(1926).—Schmidt's method is the most rapid and exact. The filicin content of fern collected in March was 18.46%, i. e., higher than in the season usually recommended for collection. The yield in the prepn. of pharmacopoeial ext was 6.84%.

Some medicinal plants growing in the Himalayas. R. N. CHOPRA and N. N. GHOSH. *Indian J. Med. Research* **13**, 533-7(1926).—A description of belladonna roots contg. 0.81% of active principles (B. P. S. and U. S. P. S. 0.45%), belladonna folia contg. 0.5% (B. P. S. and U. S. P. S. 0.30%), hyocyanus leaves and flowering tops contg. 0.03% (U. S. P. S. 0.065%) of *Valeriana wallichii* and flowering tops contg. 0.31% of essential oils, of *Podophyllum emodi* and flowering tops contg. 10.02% of resin (U. S. P. S. 3.0%), and of *Artemisia brevifolia* Wallichii and flowering tops contg. 0.5 to 2.0% of santonin. Digitalis, although not a natural plant, can be cultivated. The use of this in prepg. fresh tinctures insures a decided advance since imported digitalis is affected by the climate.

Crystalline alkaloids from the inflated lobelia. H. IESTRA. *Bull. sci. pharm.* **33**, 16-20(1926).—Several procedures are described for extg. the alkaloids from lobelia. The total alkaloidal content was about 0.4%, and the alkaloids obtained in the crystal form under the most favorable conditions were about 0.002%. The crystal. alkaloid is exceedingly active.

Certain errors in collecting and certain substitutions in commerce of medicinal plants. E. MARTIN-SANS. *Bull. sci. pharmacol.* **33**, 21-7(1926).—Ten common drug plants are discussed.

Shortening the time of percolation of ipecac and aconite roots. M. BRIDEL and M. G. BAREL. *J. pharm. chim.* [8], **2**, 49-58(1925).—In the prepn. of tinctures and exts. of ipecac and aconite roots, not only may the time of maceration be reduced from 24 hrs (Codex) to 2 hrs. (cf. R. A. Hatcher and Miss Lichtmann, *Am. J. Pharm.* 1921, 534), but a 6.5 days' percolation (Codex) may also be reduced to 24 hrs., with the same yield in active alkaloids. For ext. of ipecac, 10 parts, not 6 parts of 70% alc. (Codex) should be used for complete extn. in both cases. In the prepn. of exts. of ipecac and aconite, filtration of the liquid left after distg. off the alc., should be omitted, as it involves large losses of alkaloids.

Shortening the time of percolation of hydrastis rhizome, and the barks of yellow and red cinchona. (M. G.) G. BAREL. *J. pharm. chim.* [8], **2**, 476-84(1925); cf. preceding abstr.—Extn. of the hydrastis rhizome by the method of the Codex (1908) and by the 24-hr. method yields fluid exts. of the same alkaloidal content, although in both cases extn. of the alkaloids is incomplete, unless more alc. be used. Again, in the prepn. of soft ext., filtering after distg. off the alc. removes about 50% of the alkaloid. Very similar results are obtained with the 2 cinchona barks.

The oils, fats and waxes of the Codex. RICHARD. *J. pharm. chim.* [8], **2**, 76-87, 243-57, 443-53, 495-501(1925).—Report of the 4th Sub-Commission.

Gauzes for wound dressings. R. BERNIER. *J. pharm. chim.* [8], **2**, 120-3(1925).—Report of the 15th Sub-Commission of the Codex.

Analysis of nitrates of bismuth. PICON. *J. pharm. chim.* [8], **2**, 132-40(1925).

cf. C. A. 20, 559.—The Bi subnitrate of the Codex 1908, (A) prepd from the neutral salt with cold and very dil. HNO_3 , has the compn. $\text{N}_2\text{O}_5 \cdot \text{Bi}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, contg. 76.31% Bi_2O_3 , basicity ratio $\text{Bi}_2\text{O}_3/\text{N}_2\text{O}_5$ 4.29. A slight excess of HNO_3 evaps. upon drying at 50° . The subnitrate of the Codex 1884, (B) prepd. from the neutral salt with good yield by boiling with H_2O , has approx. the compn. $9 \text{ N}_2\text{O}_5 \cdot 10 \text{ Bi}_2\text{O}_3 \cdot 7\text{H}_2\text{O}$ (Rutten, 1902), contg. 80.86% Bi_2O_3 , ratio $\text{Bi}_2\text{O}_3/\text{N}_2\text{O}_5$ 4.77, is well crystd. and when washed and dried, does not give off nitrous vapors when in contact with org. substances. Salts crystg. from the mother liquors approach the compn. $5\text{N}_2\text{O}_5 \cdot 6\text{Bi}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$, (Rutten), ratio 5.15. Replacement of salt A by B in the new Codex is recommended, also omit detn. of H_2O , detg. only Bi_2O_3 , N_2O_5 and their ratio, this not to exceed 5.2. Cf. Corfield and Short, C. A. 18, 3617.

S. WALDBOTT

Antiseptic chlorinated liquids prepared from industrial products. M. VARDIN. *J. pharm. chim.* [8], 2, 141–2 (1925).—In com. Javel soln. det. active Cl as usual, and alky. by titrating 5–10 cc. (dild. with 10 vols. H_2O) with 5% AcOH , using litmus paper as outside indicator, and calc. quantity of AcOH for 1 l. Then mix sufficient Javel soln. for 4.5 g. Cl per l. with the calcd. quantity of 5% AcOH , 5 g. of NaCl , and enough H_2O to bring to 1 l.

S. WALDBOTT

Preparation of chlorinated antiseptic solutions. P. BRETEAU. *J. pharm. chim.* [8], 2, 142–3 (1925).—Detn. of active Cl and of alky. in Javel soln. must be made on the dild. liquid, since losses are caused by dildn. (C. A. 10, 654). Boric acid which was first used in neutralizing alky., set free HClO causing rapid decompn. "Dakin soln." as now frequently used, contains, per l. NaHCO_3 10–15 g., Javel soln. 4–5 g. active Cl and 0.25 g. KMnO_4 for greater stability of Cl content (cf. B., *J. pharm. chim.* [7], 21, 139 (1920), and C. A. 16, 2198).

S. WALDBOTT

Poisoning by white hellebore (*Veratrum album* L.); confusion with asparagus root (*Asparagus officinalis* L.). J. MAHEU AND P. CHERAMY. *J. pharm. chim.* [8], 2, 185–95 (1925).—A (non-fatal) case of poisoning led to a detailed differentiation of the macroscopic and anatomical characters of the rhizomes and roots of the 2 plants. Drawings of microscopic sections are given. The microchem. behavior of the material c. g., towards the Dragendorff-Goris reagent for *Veratrum album* confirmed the findings.

S. WALDBOTT

The need of an assay method for absorbent cotton in the codex. M. FRANÇOIS AND F. RICHARD. *J. pharm. chim.* [8], 2, 273–80 (1925); cf. Picon, C. A. 19, 2389.—A review of several standard methods, e. g., that of the U. S. P. A well-defined immersion test should be given in the Codex, allowing a mix. of 10 sec. for the time of complete wetting. The fat content, to be detd. by extn. with Et_2O , should not exceed 0.20 g. per 100 g. of cotton, and tests for ash and neutrality should be given. S. WALDBOTT

Second international conference for the unification of the formulas of potent drugs. Brussels, 1925. *J. pharm. chim.* [8], 2, 406–15 (1925).—The official final protocol. Also in *Schweiz. Apoth. Ztg.* 63, 751–60 (1925).

S. WALDBOTT

Notes on the Brussels conference. L. GRIMBERT. *J. pharm. chim.* [8], 2, 369–75 (1925); cf. preceding abstr.—A crit. discussion on the Latin titles for "Sirop diacode" and other official prepsns. and chemicals, notably NaCl , in various pharmacopeias.

S. WALDBOTT

The arsenobenzenes, their composition, toxicity, nature of the side chain, value of the D. M. index. F. DE MYTENAERE. *J. pharm. chim.* [8], 2, 417–27 (1925); cf. C. A. 17, 2471.—In answer to criticisms (cf. C. A. 19, 2103), the value of the D. M. index as of definite chem. significance, and having an evident relation to toxicity, is maintained. Valeur and Launoy (C. A. 19, 1756) failed to adhere to the given method of detn., notably as to the temp. of pptn. by H_2S . For the purpose of official control of these prepsns., det. As content (19–21%), the ratio As/N (5 to 5.6), the nature of the side chain (whether methylene sulfoxylate or methylene bisulfite), and the index D. M., whose value should not exceed 12.

S. WALDBOTT

Physiological assay of hypophyseal preparations. Technic of the assay of extracts of the posterior lobe on the uterus of the guinea pig. H. PÉNAU AND H. SIMONNET. *J. pharm. chim.* [8], 2, 513–25 (1925).—The method used is practically that of Burn and Dale (C. A. 17, 2474), Smith and MacCloskey (C. A. 18, 3227) and C. Heymans (C. A. 19, 2107). Stress is laid on obtaining trustworthy results through the use of special exact app. which is sketched and described in detail. By mounting 2 similar uteri in the same app., parallel records are obtainable for each reacting fluid. A physiol. soln. of the Locke-Tyrode type, and Voegtlin's standard soln. for comparison with the com. hypophyseal prepsns. are employed. Minute directions for procedure are given.

S. WALDBOTT

Atropine and tropine; the silicotungstate of tropine. R. HAZARD. *J. pharm.*

chim. [8], 3, 5-9(1926); cf. *C. A.* 19, 3323, 20, 71.—Tropine (*A*) may be sepd. from atropine (*B*) by the relative soly. of its silicotungstate (0.01 g. *A*:16 + cc. liquid). To a mixt. (1:1 cc.) of 1% soln. of H_2SO_4 -*B* and 1% HCl -*A* add sufficient 2% HCl to make 20 cc., then 5 cc. of Bertrand's reagent (10% aq. soln. of silicotungstic acid); after 12 hrs filter the ppt., contg. the total of *B*, evap. the filtrate contg. *A*. The ppt. in HNO_3 soln. shows Vitali's test; with the evapd. filtrate the test is neg. A method of quant. sepn. of *A* and *B* is in prepn. S. WALDBOTT

Opium and its preparations. L. DÉBOURDEAUX. *J. pharm. chim.* [8], 3, 10-2 (1926).—Recorded losses of total and sol. morphine in powd. opium (*C. A.* 7, 680) have increased further on 10 yrs.' keeping, probably caused by oxidation; the products preventing soln. of the pptd. insol. morphine (*C. A.* 5, 1660). Tincture of opium and Rousseau's laudanum of the French Codex (*C. A.* 8, 206) showed no loss of morphine at any time, while laudanum of Sydenham (*ibid*) steadily pptd. within 6 months, and afterwards, involving loss of morphine in the filtrate. When left in contact with the ppt., the original prepn. after 10 yrs. did not show loss, indicating re-soln. of the morphine, perhaps through the action of some starch-like substance. The cause of the initial decompn. is ascribed to the sol. products of *saffron*, which, therefore, should be omitted from the compn. of Sydenham's laudanum. S. WALDBOTT

Ultra-violet absorption spectra of narcotine and its decomposition products (STEINER) 3.

ARMY, HENRY V.: **The Principles of Pharmacy.** 3rd Ed. revised. Philadelphia and London: W. B. Saunders Co. 1078 pp. Cloth \$8.00. Reviewed in *Am. J. Pharm.* 98, 130(1926).

Basic ethers of quinolines. J. CALLEN. U. S. 1,572,768, Feb. 9. By the reaction of quinoline compds. with amino alcs., basic ethers of quinolines are obtained which are useful in the treatment of diseases of the heart. They are generally colorless to yellowish oils sol. in the usual org. solvents but insol. in H_2O and form 2 series of salts with HCl which retain the therapeutic properties of the free bases. α -Hydroxyepi-dimethylaminoethyl ether b_{10} 175-8° and forms 2 series of salts with HCl ; α -hydroxy- γ -methylquinoline piperidylethyl ether (obtained from α -chloroepi-dimethylaminoethyl ether) b_{17} 232-4°; α -methyl- γ -hydroxyquinoline dimethylaminoethyl ether b_{10} 190°.

Packaging medicinal and anesthetic substances. A. E. SMITH. U. S. 1,572,322 Feb. 9. Liquid and non-liquid substances such as H_2O and cocaine or like substances are enclosed in an ampule of glass or other suitable material and are sepd. from each other by a partition of paraffin or other material, which may be fused to permit intermixture of the substances. U. S. 1,572,323 also specifies packaging local anesthetics and H_2O , etc. (or other substances which are used to form unstable compns. by admixt.) in glass ampules with a sepg. partition of paraffin or other material m. 45-100°. U. S. 1,572,324 specifies similarly packaging sepd. liquids such as ingredients of local anesthetic solns. which are to be mixed at the time of use.

Compositions opaque to X-rays (for internal administration). T. THORNE-BAKTER. Brit. 241,968, June 23, 1924. A prepn. to be taken internally by a patient before radiographic examn. comprises a heavy metal salt opaque to X-rays, e. g., a jelly in which is pptd. $BaSO_4$ (formed from $BaCl_2$ and an excess of $(NH_4)_2SO_4$ and a small quantity of H_2SO_4).

Removing nicotine from tobacco. T. SCHLOESING. Brit. 234,845, May 30, 1924. Tobacco is treated with a mixt. of steam and NH_3 , the latter being continuously introduced into the app. used to maintain an appreciable pressure. Condensate is treated with "petrol" or other solvent of nicotine from which the nicotine is subsequently recovered. Brit. 242,225 specifies freeing the nicotine solvent of NH_3 by passing the solvent upwardly through H_2O which may be satd. with $NaCl$, or by bringing it into intimate contact with air.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Recovery of copper from pyrite residues in the manufacture of sulfuric acid. N. F. YUSHKEVICH. *J. Chem. Ind. Russia* 1, 5-11 (Nov.-Dec., 1924).—Pyrite contg. some Cu is used in Russia for the manuf. of H_2SO_4 by the chamber process. As by-product a cinder is obtained which contains 6.27% of Cu in the form of sulfides and sulfates. Y. investigated the best method of effecting the recovery of the Cu in the form of CuSO_4 . The methods of extg. the cinder by either H_2O or $\text{H}_2\text{O} + \text{H}_2\text{SO}_4$ gave unsatisfactory results. Y. recommends submitting the cinder to a preliminary treatment by wetting it with H_2SO_4 (8 parts by wt. of chamber H_2SO_4 to 100 parts of cinder) and furnacing at temps. between 500° and 600° to convert all the Cu into CuSO_4 and transform the Fe sulfides and sulfates into Fe_2O_3 and SO_2 . During this treatment SO_2 is formed in abundance. After this, the residue is treated first with boiling H_2O , then with boiling H_2O contg. 4% of H_2SO_4 . By this method the Cu extd. reaches 97%.
BERNARD NELSON

Means for reducing the absorption of ammonia in gas holders. KALTENBACH. *Mem. poud.* 21, 144-51 (1924).— NH_3 , stored in gas holders, is absorbed slowly by the H_2O through the interspersed layer of oil. When the absorbed NH_3 has made the H_2O specifically light enough, the NH_3 soln. rises above the oil or emulsifies with it and causes trouble. Warm NH_3 gas, satd. with H_2O , if cooled in the gas holder, deposits drops of satd. NH_3 soln. If 600 cu. m. pass per hr., and if the gas is cooled from 20° to 15° , then 108 l. condense in 24 hrs., if from 25° to 15° , then 275 l. Remedies are previous cooling of the gas, introduction of fresh H_2O at the bottom, and frequent removal of the strongly ammoniacal layer directly beneath the oil, before it has time to diffuse into the mass of H_2O .
TENNEY L. DAVIS

Manufacture of sodium chromate. N. F. YUSHKEVICH. *Trans. Inst. Econ. Mineralogy and Petrography* (Russia) 1925, No. 13, 1-29.—The influence of temp. on the velocity of the formation of chromates was studied by roasting in an elec. furnace chrome iron ore 37.85% (contg. 44.6% Cr_2O_3) with Na_2CO_3 24.3% (98.5% pure) and CaO 37.85% (90% pure). The formation of chromates at 700° is rather slow. At 1160° , 30 min. roasting is sufficient to convert 95% of Cr_2O_3 into chromates. Any diminution of soda required theoretically as indicated in the equation: $4\text{FeO} \cdot \text{Cr}_2\text{O}_3 + 8\text{Na}_2\text{CO}_3 + 7\text{O}_2 = 8\text{Na}_2\text{CrO}_4 + 2\text{Fe}_2\text{O}_3 + 8\text{CO}_2$ influences the yield of the sol. chromate. The type of furnace for the best results must maintain the following conditions: (1) The mixt. must heat rapidly to 1160° . (2) The mixt. must be constantly stirred. (3) The temp. of the heating gas must not exceed 1260° .
J. S. JOFFE

Production of sodium cyanide from atmospheric nitrogen, sodium carbonate and carbon. E. BERL AND A. BRAUNE. *Fortschritte Chem.* 18, 203-34 (1925).—The production of NaCN in accordance with the equation, $\text{Na}_2\text{CO}_3 + 4\text{C} + \text{N}_2 \rightleftharpoons 2\text{NaCN} + 3\text{CO}$, proceeds rapidly and almost quantitatively if gas diffusion is not hindered, and the CO pressure is sufficiently low. C must be present in excess; Fe or Fe oxide must be present as catalyst; and gaseous diffusion must be aided by stirring the mixt. during the process. Fusion of the material must be avoided, as it causes reversal of the reaction. The best results are obtained by using a mixt. of equal parts of Na_2CO_3 , C and Fe. Considerable quantities of Na are produced if the N is supplied at too great a rate, and the formation of Na is considered to be a necessary stage in the process. A temp. of 950 – 1000° is most suitable for the process. Ferrocyanides are formed during the process, the quantity apparently depending upon the proportion of Fe in the mixt. NaCN is converted quantitatively into NH_3 and Na formate by treatment in autoclaves with steam at 150° .
B. C. A.

Removal of sulfite and sulfate from sodium thiosulfate by crystallization. LOTHAR WÖHLER AND J. DIERKSON. *Z. angew. Chem.* 39, 33-6 (1926).—In the prepn. of $\text{Na}_2\text{S}_2\text{O}_3$, Na_2SO_3 and Na_2SO_4 are generally present as impurities in the crude liquor. The authors have studied the soly. isotherms of the 3 binary systems at 23° , 40° , 60° and 80° , together with the ternary system, equil. diagrams being shown. From the data given it is possible to start with any mixt. of the 3 salts, and obtain pure $\text{Na}_2\text{S}_2\text{O}_3$ by evapn. and crystn. at the proper temp. Soly. curves of the 3 salts taken separately are also shown.
H. STROBTZ

Deterioration of commercially packed chlorinated lime. C. C. McDONNELL AND LESLIE HART. *U. S. Dept. Agr. Bull.* 1389, 1-19 (1926).—The available Cl in samples of bleaching powder packed in containers of the usual com. type as a rule decreases fairly regularly during storage on account of the conversion of the Cl into CaCl_2 . No

marked difference was noted in the rate of deterioration between samples manufactured and packed in winter, and in summer, but the loss of available Cl was greater in warm than in cold weather, the av. loss for the hottest months of the year being 1.44% per month and for the coldest months 0.61%. A comparison of samples stored in glass bottles in the light with those stored in the dark indicates that light rays slightly accelerate the loss of available Cl.

W. H. ROSS

Factors governing lime-kiln capacity and fuel economy. V. J. AZBE. *Nat. Lime Assoc. Tech. Papers and Addresses* 1925, 37-58.—An attempt to establish a standard of comparison and an outline of the basis for these standards. The principal points cover higher fuel efficiency, higher kiln capacity, longer kiln running periods and better lime. Min. fuel cost should be the chief aim. "Too large amts. of excess air used for burning of fuel are responsible to a great extent for inefficiency of lime kilns." Heat loss by radiation and the bearing of kiln gas analysis on kiln efficiency are pointed out. The methods of firing, kiln running periods and kiln refractories are discussed. Few kilns, if any, show 50% thermal efficiency.

W. H. BOYNTON

Measurement of kiln performance. W. K. LEWIS AND A. H. RADASCH. *Chem. Met. Eng.* 33, 76-8(1926).—Calcns. are given for keeping a quant. check on a lime kiln during its operation through gas analysis and other detns. Comparison is made between kilns with and without the Eldred-Dougherty recirculation system. Higher quality and uniformity of product are the advantages of this system rather than lower cost of operation.

H. F. K.

The use and revivification of decolorizing carbon. BERTHOLD BLOCK. *Chem. App.* 12, 222-4, 242-4(1925); 13, 4-6, 27-30(1926).—A general description with many references to Ger. patents, and 15 cuts of app. and plant.

J. H. MOORE

Anti-freezing solutions for motor radiators. C. E. MULLIN. *Textile World* 69, 81, 119(1926); *Textile Recorder* 43, No. 513, 95(1925).—The use of alc., glycerol, honey glucose, CaCl_2 and kerosene are discussed.

CHAS. E. MULLIN

The structure of casein plastics. K. HAUPT AND M. WAECHEER. *Kunststoffe* 15, 129-31(1925); *Plastics* 2, 45-6, 58(1926).—By optical examn. of thin pieces of extruded casein plastic the stresses set up are studied. By the use of modern macerating and mixing machinery a uniform product is secured. Drying should be slow enough to allow a uniform rate of shrinkage. The main problem is in connection with the stresses set up by the selective tanning action of formaldehyde in the various concentric layers of the plastic rods.

Thermal decomposition of sulfates (MARCHAL) 2. Natural and artificial pearls (BOUTAN) III. Apparatus for evaporating brine (Brit. pat. 242,018) 1.

BRAIDY, H.: *La fabrication de l'acide sulfurique par le procédé de contact.* Paris: H. Mounier. 302 + xi pp. 15 francs. Reviewed in *Chimie et industrie* 15, 160(1925).

PARRISH, P.: *Sulphuric Acid Reaction Chambers.* London: Ernest Benn Brothers. 159 pp. 6s.

Purifying hydrocyanic acid. M. WALKER. U. S. 1,571,982, Feb. 9. Liquid HCN contg. H_2S is treated with SO_2 .

Scrubber or absorber for nitrous fumes evolved in nitric acid manufacture, etc. CHEMISCHE WERKE LOTHRINGEN GES. Brit. 236,918, July 10, 1924.

Absorption of nitrous gases in water. OLAF JENSEN. Norw. 42,212, Dec. 7, 1925. The gases are absorbed by thin films of water applied on cooled surface by which the heat of absorption is removed from the soln. as quickly as possible and without any evapn. of water. The temp. of the soln. is kept between 0° and 10° .

Ammonia. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 42,179, Nov. 23, 1925. The process described in Norw. 40,640 (C. A. 19, 1329) is carried out under increased pressure.

Borax and sodium bicarbonate from lake brines. M. V. LOWRY. U. S. 1,573,259, Feb. 16. A brine, previously concd. by evapn., is carbonated and cooled so that crystal borax and NaHCO_3 are pptd. as a sludge. The sludge is mixed with colemanite and heated to about the b. p. to dissolve borax from the sludge.

Purifying zinc sulfate solutions. R. B. ELDRIDGE. U. S. 1,573,233, Feb. 16. Impure ZnSO_4 solns. are treated with Zn hyposulfite or other sol. hyposulfite to ppt. impurities such as Co, Ni, Mn, Fe, Cu, Hg, Cd, As, Sb, Ag, Au, Pb, Bi, Tl, Se or Te.

Drying calcium hypochlorite compounds. G. PISTOR. U. S. 1,572,952, Feb. 16. Preliminary drying is effected by heating and the material, still contg. a small pro-

portion of H_2O , is then mixed with a hygroscopic substance such as CaO or calcined gypsum which does not decompose the hypochlorite.

Mining sulfur. W. C. AVERILL, JR. U. S. 1,573,026, Feb. 16. Sand is caused to flow from an overlying stratum to fill channels and cavities in a S-bearing stratum and retard the escape of hot H_2O from the vicinity of a well.

Creosote from corn cob distillation. F. C. ATKINSON. U. S. 1,572,510, Feb. 9. Crushed corn cobs are extd. with steam under pressure, dried and then destructively distd. in a closed retort at high temp. The oily portion is sepd. from the rest of the collected distillate and is redistd.

Silica gel. CHEMISCHE FABRIK AUF ACTIEN (VORM. F. SCHERING). Brit. 242,234, Nov. 3, 1924. Silica gel is washed until it contains about 2% of salt (calcd. on the wt of the dried product) and the washing is then discontinued without removing the residual electrolyte.

Coloring granular mineral substances. H. C. FISHER. U. S. 1,572,425, Feb. 9. Granulated slate or other granular mineral material is mixed dry with ultramarine blue or other pigment insol. in H_2O ; H_2O and a sol. silicate are then added and the agitated mixt. is dried by heat.

Wood for sound amplifying horns, etc. POLYPHONWERKE AKT.-GES. AND H. WÜNSCH. Brit. 242,117, Jan. 7, 1925. Compressed air or CO_2 is used for spraying and impregnating horns or similar articles of wood, with a compn. of port. cement 1, lime 4, plaster 4, $NaCl$ 1 and "sol. glass" 1 part, or with similar compns.

Hard molded articles from calcined magnesia. O. FROSELL. U. S. 1,572,714, Feb. 9. Imitation marble or other articles are formed of calcined magnesia which is set by hydration with H_2O under the simultaneous action of heat and compacting pressure.

Solid composition for absorbing and purifying waste combustion gases. J. C. TATE. U. S. 1,573,284, Feb. 16. A hard porous mass formed of lime bonded with burned gypsum is used for treating gases such as those from the combustion of animal or vegetable materials.

Dust-laying composition. R. GILBERT. Brit. 236,731, July 15, 1924. A mineral oil of 6.89 sp. gr. at 15° , close flash point about 175° and Redwood viscosity of 182 sec. at 20° and 50 sec. at 60° , is mixed with about 5% of com. cresols.

Molding aircraft fuselages, boats or similar articles, of phenolic condensation products. R. KEMP. U. S. 1,572,936, Feb. 16. Pressure-exerting members of molding app. are formed in part of Bi, Sn, Pb alloy or other material of relatively low m. p. and in part of another material of higher m. p.

Diaphragms for sound reproduction. J. GRAHAM. Brit. 236,699, May 17, 1924. Two or more layers of dressed pig skin (between which Fe filings may be placed) are joined by lignum-vitae gum or other adhesive.

Vertical shaft lime kiln. H. MISCAMBELL. U. S. 1,572,156, Feb. 9.

Mixture for protecting the skin from dirt, oil, grease, etc. D. R. KELLOGG. Brit. 236,069, Aug. 26, 1924. Bentonite 17, soap $4\frac{1}{2}$ and H_2O 78 $\frac{1}{2}$ %.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

The South's possibilities for glass and portland cement industries. G. R. SHELTON. *Manufacturers Record* 89, 55(1926). F. G. J.

Glasses and glazes in ancient Assyria. ANON. *Pottery Gaz. Glass Trade Rev.* 51, 87-9(1926).—The information given is taken from Assyrian cuneiform tablets which have recently been deciphered by R. C. Thompson. Approx. formulas, source of materials and methods of prepn. are given. R. E. G.

Plan for reclaiming 12% waste gases from glass tank. R. R. MEYER. *Ceramic Industry* 6, 148-53(1926).—A suggested system to reclaim 100 to 150 h. p. per ton of coal used in melting of glass, from waste heat. In most factories this heat could be used to good advantage in making steam for gas producers. R. E. G.

Ceramics and road materials. Ceramic industry. HOWELLS FRÉCHETTE. Can. Dept. Mines, *Mines Branch* No. 645, 1-7(1925).—A review is given of the ceramic industry in 5 of the Canadian provinces. Lab. tests of various clays best suited for ceramic purposes are reported. Cost of burning brick and tile. L. P. COLLIN. *Ibid* 8-17.—Data taken from 16 burnings in 14 plants showed that the cost of setting ranged

per ton from \$0.13 to 0.44, firing \$0.05 to 0.58, unloading \$0.12 to 0.54, fuel \$0.50 to 1.90, total cost \$1.07 to 2.44. These figures indicate that much improvement may be made in lowering the cost especially in the matter of fuel. Samples of clay from 43 localities were tested. Road materials in New Brunswick and Nova Scotia. R. H. PICHER. *Ibid* 18-45.—Granulometric analyses and phys. tests of 66 samples of road gravels are reported. Forty-two samples of bed rock in this region and in Quebec were tested for their fitness for road material. L. W. RIGGS

The constitutional changes occurring in clays on heating. THE RESEARCH STAFF OF THE GENERAL ELECTRIC CO. *Trans. Ceram. Soc. (Eng.)* 24, 402-6(1924-25).—The data presented resulted from an attempt to follow, by X-ray methods, the 500° and 900° changes in kaolinite, and to obtain information upon the stable compds. formed in fired clay. The facts established by the X-ray study of the constitutional changes in clay are: kaolinite completely breaks down at about 600°, forming a silicate which is stable to about 900°. This silicate is presumably $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$. At the higher temps. mullite is formed; the X-ray patterns of natural sillimanite and of mullite prepd. by heating andalusite at 1550° for 5 hrs. are different. The pattern of the mullite agrees with those obtained from fired clay mats. The mineral formed in clays at about 1000° is mullite and not sillimanite. The formation of mullite occurs in all the clays examd. by heating for 5 hrs. at 1050°. The temp. at which complete stability is reached—i. e., the point at which there exists only transformed quartz and mullite in the fired clay—varies according to the nature of the clay. R. F. S

Chemical transformations of kaolinite at high temperatures. P. A. ZHEMYAT CHENSKII. *Ann. Inst. Anal. Phys.-Chim. Leningrad* 2, 499-500(1924).—On the basis of the behavior of kaolin towards 5% Na_2CO_3 soln., which indicates absence of free silicic acid, Z. concludes that the kaolin mol. remains undecomposed at the temp. of complete dehydration, namely, 600-700°. B. C. A.

Behavior of kaolin at a high temperature. V. I. ISKUL. *Ann. Inst. Anal. Phys.-Chim. Leningrad* 2, 498-9(1924).—A sample of kaolin contg. 44.16% SiO_2 , 38.24% Al_2O_3 , 13.35% H_2O , and small proportions of various other oxides, lost its H_2O at a dull red heat and was then readily decomposed by 2% HCl soln., but the anhyd $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$ did not decompose. At 1000-1100°, this residue was decomposed into a substance of the compn. of sillimanite, $\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$, and SiO_2 , which could be dissolved by 10% KOH soln. A second sample of kaolin, contg. 48.44% SiO_2 and 34.68% Al_2O_3 , and thus more SiO_2 than corresponds with the formula, $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$, exhibited no free SiO_2 in the form of granules of quartz; after dehydration this sample behaved towards reagents similarly to the previous one, but when heated to a higher temp. and then treated with 10% KOH soln., it left a residue having approx. the compn. of the aluminosilicate, $2\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$. The basis of this kaolin is, therefore, probably not kaolinite, but either another aluminosilicate or a mixt. of aluminosilicates. B. C. A.

Note on a new method for the determination of porosity. P. B. ROBINSON. *J. Soc. Chem. Ind.* 45, 33-4T(1926).—The usual porosity detn. of prolonged boiling in H_2O or soaking under reduced pressure was found to be incomplete even after 72 hrs with brick of about 30% porosity. The method suggested is based on the difference between the bulk sp. gr. of the brick when coated with a thin layer of plasticine and the true sp. gr. of the powd. material. Porosity = $100 [1 - (\text{bulk sp. gr. brick} \div \text{true sp. gr. powd.})] \%$. H. F. K

The application and grinding of engobes. P. JÜRGEI. *Keram. Rundschau* 34, 17-9(1926).—Engobes are white or colored slips which are applied to leather-hard bodies to conceal the more undesirable color of the body. Many natural clays are used as engobes. The engobe should have the same shrinkage as the body. If white engobes have a cream tinge, 0.01-0.02% CoO may be added. The addn. of ZnO to the slip may greatly whiten the color but is too expensive for ordinary work. The slip is usually applied by pouring it in a leather-hard vessel and emptying out the excess. A common defect is pinholing, which comes chiefly from applying the slip to ware which is too dry. Dry ware is more or less porous and when the H_2O is absorbed by the ware gases are forced through the slip causing pinholes. Another source of pinholes is fermentation of the engobe. This often originates from old wooden containers which have started to decay. If dark clays are used in the engobe they often contain pyrites which may cause pinholing during firing since gases are given off. Grinding the clay and hence the pyrites finer will tend to overcome this trouble. Typical compns. of some engobes are given. To produce engobes of different colors, oxides may be added as follows: For brown, Fe or Mn oxides; for blue, CoO ; for green, Cu or Cr oxides; for yellow, small quantities of Fe_2O_3 or TiO_2 ; for black, a mixt. of Fe, Cr and Co oxides. About 2-6%

of these oxides usually give the desired colors. Many effects may be produced by using 2 or more colored engobes. Glazes as a rule are applied over the engobes but if 30–50% of the glaze is added direct to the engobe mat finishes are produced which do not require a glaze.

H. G. SCHURECHT

The selection of refractory materials used in industrial chemistry. A. B. SEARLE. *Ind. Chemist* 2, 51–3 (1926).

E. H.

The use of silica refractories. P. B. ROBINSON. *J. Soc. Chem. Ind.* 45, 29–33T (1926).—A general discussion of the use of silica brick is given, the inversion changes which are commonly observed being followed with precautions to prevent phys. failure due to buckling of walls and spalling of the brick. New data are given to show the greater heat cond. of silica brick at all temps. over fireclay brick. The effect of exposure and wetting is studied, showing that soln. of some of the bond as well as phys. effects weaken silica brick, especially those underburnt.

H. F. K.

Carborundum refractories. IAN STEWART. *Chem. Eng. Mining Rev.* 18, 151–4 (Jan. 1926); cf. C. A. 20, 712.—The most important type of carborundum refractory contains over 90% pure cryst. and infusible SiC, bonded by the addition of a small amt. of highly refractory but fusible materials. Carborundum is infusible but decomposes at approx. 2300°. Its thermal cond. is 8–10 times that of fireclay or silica. A new type of radiating combustion chamber is described, in which liquid, gaseous, or pulverized fuels are burned in a flue of small cross section but considerable length, composed of SiC tile less than 2 in. thick. With this type it is possible to burn liquid and gaseous fuel at a rate equal to 375,000 B. t. u. per cu. ft. of combustion space per hr., and pulverized coal at the rate of 225,000 B. t. u. per cu. ft. per hr. Finely divided sponge Fe was produced on a commercial basis, and a decrease in fuel consumption of 25 to 35% with an increased production has been effected in the porcelain enameling industry. There is also a large field for SiC in the steel industry, despite its high cost.

H. STROETZ

Preparation and constitution of German insulator bodies. E. THIESS. *Ceramic Industry* 6, 191–2 (1926).—The German and Bohemian high-tension porcelain consists of 47–50% kaolin and white-burning clays, 30–25% feldspar (Sweden) and 23–25% quartz sand or rock quartz (Norway). About 90% of the German bodies are prepd. by grinding in ball mills. Most factories age the clay for long periods of time before working. Most of the ware is fired to cone 14 or higher.

R. E. G.

Porcelain for high tension insulators. K. H. REICHAU. *Trans. Ceram. Soc. (Eng.)* 24, 279–99 (1924–5).—Phys. properties are discussed.

Clay for pottery. J. E. TAMS. Brit. 242,089, Nov. 22, 1924. A "semi-porcelain" compn. for making pottery comprises ball clay, china clay, ground flint and MgO or other suitable Mg compd. (excepting hydrated Mg silicate), all blunged together. Cf. C. A. 19, 2732.

Clay mixture for pottery. J. E. TAMS. Brit. 242,091, Nov. 24, 1924. Bone 10¹/₄, china clay 5¹/₂, and hydrated Mg silicate 1¹/₂ parts are blunged together. Cf. C. A. 19, 2732.

Apparatus for removing air from pottery clay, etc., by vacuum treatment. BULLERS, LTD., F. R. PENNELL and E. J. HACKLEY. Brit. 236,687, April 28, 1924.

Fused silica articles. QUARTZ ET SILICE. Brit. 242,214, Oct. 30, 1924. Elec.

insulators, measures, etc., formed of fused SiO_2 , are superficially worked with a grinding wheel or like device having a hardness of not less than 7 on Mohr's scale. This removes the porous skin from the article and avoids the need of superficial remelting.

Kiln for drying and burning bricks. A. HABLA. Brit. 242,051, Oct. 8, 1924.

Tunnel kiln adapted for drying brick, etc. H. R. STRAIGHT. U. S. 1,572,326, Feb. 9.

Continuous tunnel kiln adapted for burning brick, tile, etc. H. R. STRAIGHT. U. S. 1,572,327, Feb. 9.

Abrasive. M. L. HARTMANN. U. S. 1,573,061, Feb. 16. Abrasive articles which may be formed mainly of SiC_2 , Al_2O_3 or similar materials have their voids filled with a lubricant such as graphite or talc which does not fuse by the heat normally created by abrasive action. A binder such as dextrin is also used with the lubricant.

Refractory ceramic material. F. M. LOCKE and F. J. LOCKE. U. S. 1,572,730, Feb. 9. A batch for making elec. insulators or other refractory articles comprises clay mixed with about 1-15% of MnO_2 or similar Mn compd. which serves to produce a product resistant to high voltages even when heated.

Refractory lining for crucibles, etc. F. C. FRARY. U. S. 1,572,475, Feb. 9. A steel shell is lined with fine particles of Al_2O_3 bound together by Na silicate.

Refractory walls for safes, etc. SOC. BOURNISIEN, BEAU, ET CIE. Brit. 242,267, Oct. 29, 1925. Zircon or similar material (which may be agglomerated by magnesia cement) is embodied in the walls of safes, etc., to resist attack by oxy- C_2H_2 blowpipe flame.

20---CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Use of sulfur in rendering cement drain tile resistant to the attack of alkali. F. H. BATES. *Ind. Eng. Chem.* **18**, 309(1926).—Impregnating drain tile with molten S greatly increased the tensile strength and reduced absorption. Impregnated tile, placed in a western alkali soil, completely disintegrated in 2 years. No satisfactory explanation of this rapid disintegration was found; but free S reacted readily with solns of lime water from concrete.

Determination of the quality of concrete. ROBERT STUMPER. *Bull. soc. chim. Belg.* **34**, 296-303(1925).—The quality of concrete being defined by the ratio of cement, sand in the mixt., formulas are derived for the calcn. of this ratio from the SiO_2 or CaO content of the cement, sand, and concrete.

Testing the materials to be used for the building of the Aaensire dam. N. HAA VARDSHOLM. *Teknisk Ukeblad* **72**, 457-60, 467-70, 477-80(1925).—The effect of the addn. of certain cheaper hydraulic materials, for instance artificial trass, or finely ground coal slags and brick waste to the mortar was studied. The mixed mortars showed a marked superiority in crushing strength and resistance to water penetration. Especially the addn. of 0.6 parts of powd. slag from coal or coke to 1 part of cement gave an excellent concrete for dam constructions.

The South's possibilities for glass and port. cement industries (SHELTON) **19**. Bituminous emulsions for use in road-making (Brit. pat. 236,641) **22**. Gas-fired shaft furnace for burning cement (Brit. pat. 236,776) **1**.

MAY, PETER. *Praktische Winke für Zement und Beton*. Berlin: W. ERNST & SOHN. 122 pp. R. M. 6.

Cement mixtures. J. U. A. OHLSEN. Brit. 236,827, Jan. 16, 1925. Infusorial earth, moler or the like are impregnated with bituminous or resinous substances and used as aggregate with Sorel cement or other cements, with or without asbestos, slag wool or other fillers, and the mixt. is molded under pressure.

Refractory cement and concrete. P. J. F. KESTNER. U. S. 1,573,072, Feb. 16. See Brit. 231,141 (C. A. **19**, 3576).

Plaster. V. LEFEBURE. Brit. 236,695, May 8, 1924. Salts such as Na_2SO_4 , K_2SO_4 , Na_2CO_3 , K_2CO_3 or alum are added to ground anhydrite in the proportion of 0.125-2.0%.

"Substitute for lumber" from bagasse. J. K. SHAW. U. S. 1,572,565, Feb. 9. Bagasse fibers are cooked together with their natural pith and with the addn. of alkali

to loosen encrusting substances (but insufficiently for paper-making) and a "lumber substitute" is formed from the fibers by H_2O deposition.

Impregnating wood. O. V. STEWART. U. S. 1,572,905, Feb. 16. Wood elec. insulators or wood in other forms is impregnated with paraffin in its inner portions and is then superficially impregnated with asphalt.

Bituminous expansion joints (for concrete, etc.) containing corncob fiber. A. C. FISCHER. U. S. 1,571,874, Feb. 2.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Fuels and combustion. ANON. *Power* 63, 8-12(1926). --A review. D. B. D.

Principles of modern heat economy. CURT WEISSBACH. *Apparatebau* 38, 30-2 (1926); 6 cuts. J. H. MOORE

A rational utilization of low-grade combustibles. GAETANO CASTELLI. *Russ. min. mel. chim.* 64, 10-2(1926).—Various methods are described which have been developed in different countries for utilizing low-grade fuels in the most economical manner. The prepn. of fuels by some of these methods, particularly flotation and low-temp. carbonization, would result in considerable saving in certain Italian industries, such as cement and glass manu. C. C. DAVIS

Motor fuels. A. PIRLOT. *Bull. fed. ind. chim. Belg.* 4, 387-402, 463-71(1925).

A general discussion with special reference to the production of EtOH for motor fuel and its utilization in admixt. with C_6H_6 , tetralin, etc. W. B. PLUMMER

Value of liquid fuels (in internal-combustion engines). P. DUMANOIS. *Compt. rend.* 181, 26-8(1925).—The fuel consumption of a motor engine over long distances averaged 22 l. per 100 km. with MeOH; 11.6 l. with a mixt. of 50% of gasoline and 50% of EtOH, 12.7 l. with a mixt. of 80% of gasoline and 20% of kerosene contg. 0.2% of lead tetraethyl, and 11.7 l. with a mixt. of 70% of gasoline and 30% of kerosene contg. 0.2% of lead tetraethyl. The corresponding max. speeds obtainable were 80, 85, 93 and 90 km. per hr. Although the consumption of MeOH is twice that of gasoline the equiv. calorific power is less. The addn. of 5% of water to the MeOH prevents back-firing, which frequently occurs, without detonation, however, with the pure alc. B. C. A.

The calculation of constants (index numbers) for benzine, benzene and similar substances. WA. OSTWALD. *Z. angew. Chem.* 39, 98-9(1926).—The differences between boiling curves, as given by various types of standard app. and procedures, and the impossibility of comparing directly the results from one kind with those of another accurately, have led to the use of a const. obtained by a rough integration (adding the temps. of 5, 15, etc., vol. % and dividing the sum by 10) of the b. p. curves themselves. Such a method is not applicable when different kinds of liquids are present in a sample, as in "benzene spirit." The following const. are proposed: 96-104°, BV motor benzene; 112-120°, high test benzenes for automobile fuel; 120-130°, (especially 126-128°) av. benzene for automobile fuel; and 140°, U. S. Navy quality. In detg. the possible uses of benzenes and benzenes the form of the boiling curve is not as helpful as is the const. described above. The const. makes possible a grading of such fuels with respect to their behavior upon boiling, and also enables calcs. concerning mixts. of fuels to be made. Also in *Petroleum Z.* 21, 1323-8(1925). W. C. EBAUGH

Flammable liquid fuels and the methods of rendering them industrially safe. A. RIEDLER. *Oesterr. Chem.-Ztg.* 27, 91-5, 100-6(1924).—Polemical. An answer to Strache (*C. A.* 18, 1572). R. defends the Martini Huneke system of protecting flammable liquids by excluding air from them at all times with inert gas, CO_2 or flue gases, as the only safe system and attacks Strache's method of avoiding explosive mixts. by satg. the air over the liquid with the vapor of the liquid itself, showing that it does not give protection except within a certain range of temps. for a given flammable liquid, outside which explosive mixts. are formed by bubbling air through them, particularly when the liquids are cold, and the time of mixing is short. The point is supported by tables and curves of vapor pressure vs. explosive limits for various flammable liquids, and by a practical test on supposedly satd. air-vapor mixts. from gasoline tanks protected by the "saturation method." The practical test indicated that time of mixing is the most important factor in detg. the efficacy of this method. The satn. method fails fully to protect empty tanks from explosion hazard, while the Martini-Huneke system protects empty tanks as well as full ones, by maintaining at all times an inert atm. The balance of the paper is mostly polemical against Strache, with more det.

tailed comparison of the Martini-Hunke system, and the "saturation method" as installed by Dabeg (Dampfapparatebau Gesellschaft in Wien). C. L. JONES

Complete utilization of coal and the motor fuel supply. A. C. FIELDNER AND R. L. BROWN. *Refr. & Nat. Gasoline Mfr.* 4, No. II, 83(1925); *Blast Furnace & Steel Plant* 14, 138-40, 148(1926).—Diesel type engines using heavier oils, gas producers, using coke and semi-coke, and even compressed gas engines may be used in the future, especially on trucks. The most promising solution of the motor fuel problem is production by synthesis from coal gas and water gas. M. BETH HART

Economical coal buying. H. B. STANTON. *Power* 63, 140-3(1926).—The short comings of purchasing coal on a heat unit basis are pointed out. Practical suggestions are offered for selecting coal on a performance basis. D. B. DILL

Pulverized coal. K. C. BARRELL. *Proc. Inst. Mech. Eng.* 1926, 37-50.—Prepn and uses are described. E. H.

Rapid determination of sulfur in coal. A. KOMAROVSKII AND A. KOGON. *Lehrkanzeln wiss. Forsch. Odessa* 1925, [4], 5 pp.—Coal (0.5 g.) mixed with 5 g. of a mixt. of equal parts of Na carbonate and KMnO_4 , and covered with 5 g. of the same mixt. in a metal crucible of 150-170 cc. capacity, is heated below redness for 30 min., and then to incandescence for 20 min., the mixt. being stirred with an Fe rod during the heating. The product is extd. with water, and sulfate detd. by the usual method. Results differ from those obtained by Eschka's method by -0.11% to $+0.07\%$. B. C. A.

Coal and oxygen. S. W. PARR AND F. B. HOBART. *Trans. Am. Inst. Mining Met. Eng.* 71, 216-26(1925).—Cf. C. A. 19, 1339. W. B. PLUMMER

Modern views of the chemistry of coals of different ranks as conglomerates. A. C. FIELDNER AND J. D. DAVIS. *Trans. Am. Inst. Mining Met. Eng.* 71, 227-45(1925).—A bibliographical review and discussion of coal classification, its microscopic examination, the action of solvents, of chem. reagents, of O under pressure, of reducing agents, and of destructive distn. W. B. PLUMMER

Resolution of coal by oxidation. W. FRANCIS AND R. V. WHEELER. *Trans. Am. Inst. Mining Met. Eng.* 71, 165-75(1925).—Cf. C. A. 19, 1484. W. B. P.

Constitution of coal. F. V. TIDESWELL AND R. V. WHEELER. *Trans. Am. Inst. Mining Met. Eng.* 71, 176-83(1925).—A general discussion (cf. C. A. 19, 1483) in particular emphasizing the humic nature of vitrain and its constitutional similarity to dopplerite (the latter "pure" humin occasionally found as jelly-like inclusions in peat). W. B. PLUMMER

Selective combustion in coal. F. S. SINNATT. *Trans. Am. Inst. Mining Met. Eng.* 71, 189-210(1925).—Mainly a review of the work of S. and associates (cf. C. A. 19, 161) on the propagation of a partial combustion zone through powd. coal. W. B. P.

Heat value of coal. W. F. SCHAPHORST. *Can. Chem. Met.* 10, 40(1926).—A chart is given graphically representing Dulong's formula for the calcn. of the heating value of coal from its compn. W. B. PLUMMER

Nitrogenous constituents of coal. J. W. COBB. *Trans. Am. Inst. Mining Met. Eng.* 71, 211-5(1925).—A brief but quite thoroughly bibliographical review of the literature on the forms and reactions of N in coal. W. B. PLUMMER

The elimination of explosives in coal mines by the use of sulfur dioxide. J. A. S. RITSON AND J. CROSSLAND. *Colliery Guardian* 131, 253-4(1926).—It was considered possible that SO_2 could be made to attack the carbonates of coal partings and the resulting disintegration eliminate the necessity of blasting. Expts. under various conditions, however, in which SO_2 was passed into the seams, indicate that its use is impracticable. The quantity of SO_2 per hr. was limited by the natural characteristics of the coal and the max. which could be used was about 0.25 lb. per bore hole per hr. The cohesion of the coal seams was not reduced and even if SO_2 did render the coal easier to mine, the cost would probably be prohibitive. The escape of CH_4 through the boreholes in fact rendered the coal more difficult to mine. C. C. DAVIS

The chemical composition of durain. N. SIMPKIN. *Colliery Guardian* 131, 198(1926).—The ash of durain from Lancashire seams varied from 1.16 to 28%, and in some cases was less than that from the remainder of the seams. The ash usually varied from white to pale brown in color. It was highly refractory, with a m. p. over 1400° , even when the coal from which it was obtained had a readily fusible ash. The volatile varied considerably, even when allowance was made for differences in H_2O and ash. Coke prepd. at 900° was barely coherent, but in some cases was very hard, the agglutinating value in each case being lower than that of the remainder of the coal. In all cases the % S was far lower than that in the remainder of the coal, usually 0.5-0.7%, but reaching in 1 case about 2%. The calorific value compared favorably with the

whole seams. The yields of gas were usually lower and those of liquor higher from the durain than from the remainder of the coal.

C. C. DAVIS

A proposed standard method for the determination of the agglutinating value of coal. M. BARASH. *Colliery Guardian* 131, 197-8(1926).—A coal may be regarded as composed of 2 parts: (1) a smaller fusible portion which gives on distn. a cellular, vitreous mass, and (2) a larger infusible, "inert" portion. There is at present no method for detg. the amt. of the first portion, for no method could be found in which this portion was not increased or diminished during attempts to sep. it from the infusible portion. The inert portion exerts a remarkable and hitherto unrecognized influence on the agglutinating properties of the fusible portions, and the nature of this infusible portion is perhaps the most important factor in the quality of the coke. During carbonization the fusible portion is partially absorbed by capillary action into the pores of the infusible portion. The relative porosity of the latter thus det. the amt. of the fusible portion left available for binding together the coke mass. This absorptive property is influenced by the method of treating the coal. Different methods of heating, chem. treatment or even weathering change the porosity of the infusible portion, thus changing in turn the agglutinating value of the coal. The most economical method of controlling the latter property is by blending different coals.

C. C. DAVIS

The liquefaction of coal. F. BERGIUS. *Petroleum Z.* 22, 76(1926).—Carefully conducted expts. showed that the reactions of coal liquefaction are largely exothermic. Org. material which is not sol. in benzene always remains. The amt. of this decreases with the first rise in temp. but later increases. Its min. value is characteristic for every coal, being less than 1% for lignite and about 10% for gas coal (cf. C. A. 20, 654).

M. BETH HART

Liquefaction of coal. J. RUBINFELD. *Allgem. oesterr. chem. tech.-Ztg.* 43, 151 (1925).—There are 4 methods by which motor fuel can be produced: (1) by low- and high-temp. carbonization of coal; (2) F. Fischer's Synthol process, (3) the Bergius process; (4) the process of the Badische Anilin u. Soda Fabrik. The Bergius process is slow to develop because of the high cost of the app. and the special type of coal necessary for the process.

M. BETH HART

Effect of briquetting of sub-bituminous coal. H. K. BENSON, J. N. BORGLIN AND R. K. ROURKE. *Ind. Eng. Chem.* 18, 116-7(1926).—A low-grade non-caking Washington coal with 15.5% water and 33.5% volatile (air dry) yielded a firm coke on carbonization at 700-950° after the addn. of 3% S and 8% California asphalt. The effect of S addn. is briefly discussed.

H. L. OLIN

Analysis of Alabama coals—analyses of mine samples. A. C. FIELDNER, H. M. COOPER AND F. D. OSGOOD. *Bur. of Mines, Tech. Paper* 347, 12-45(1925).—Proximate and ultimate analyses and results of calorific value and ash softening tests of a large no. of samples of Alabama coals—the sixth of a series of reports by states. Analyses of delivered coal. N. H. SNYDER. *Ibid* 100-7.

H. L. OLIN

Coal ash and clean coal. I. The formation and constitution of coal. R. LESSING. *Colliery Guardian* 131, 194-5(1926).—A discussion of the economic significance of the mineral components of coal, the influence of inorg. compds. on its formation, inorg. plant components, mineral matter after the formation of the coal and its distribution in the coal, chem. changes during incineration, analysis of the ash, the phys. structure of the mineral components and X-ray examn. II. Mineral matter and production. *Ibid* 255-6.—A discussion of chem. methods of mining coal, spontaneous combustion, prepn. for the market, flotation processes, drying, dry-cleaning, the control of washing and cleaning and sampling. Also in *J. Roy. Soc. Arts* 74, 182-97, 205-18(1926).

C. C. DAVIS

Steam and boiler coal consumptions, and the determination of costs, in drying brown coal. K. DEIMLER. *Braunkohle* 24, 933-41(1926).—A continuation of previous discussion (C. A. 19, 2401), extensive charts and tables for the detn. of fuel consumptions for varying per cents of H₂O in the raw coal and varying sp. heats of the dry coal, etc.

W. B. P.

Briquetting sawdust and wood waste. J. PETITPAS. *Bull. soc. d'encour.* 124, 399-408(1925).—The sawdust is treated with a dil. aq. soln. contg. glue and starchy materials, the quantity of water or soln. required being detd. graphically from the absorptive capacity of the sawdust. In order to obtain an even penetration the glue soln. is made alk. and the sawdust brought to a standard moisture content. The jelly-like mass is subjected to pressure, the presence of the alkali increasing the effect on the sawdust. A hard and durable, readily combustible briquet is thereby produced.

B. C. A.

Elimination and recovery of phenols from crude ammonia liquors. R. M. CRAW-

FORD. *Ind. Eng. Chem.* **18**, 313-5; *Blast Furnace & Steel Plant* **14**, 112-4, 154 (1926).—Description of plants built (3 installations) by the Foundation Oven Co. for removing phenols by scrubbing with C_6H_6 . Two extn. towers are used, having a downwards flow of NH_3 liquor and an upwards "spray" of C_6H_6 , 2 more towers serving to ext. the phenols from the C_6H_6 by NaOH soln. from which they are liberated by CO_2 or H_2SO_4 . With NH_3 liquor contg. 2 g./l. of phenols, consumptions and yields per 1000 gals. liquor treated are NaOH 14 lbs., C_6H_6 (loss) 5 lbs., com. concd. H_2SO_4 17 lbs or CO_2 9 lbs., phenols obtained (crude) 16.6 lbs., Na_2CO_3 obtained (if CO_2 is used) 18 lbs. The crude phenols are 12% H_2O , 51% PhOH, 26% cresols (mainly *o*-), and 11% higher acids and residue.

W. B. PLUMMER

Low-temperature coking benefits coal. R. DAWSON HALL. *Coal Age* **29**, 112-4 (1925).—A review of the present status of the Trent amalgam, McEwen-Runge and other methods for processing coal.

H. L. OLIN

Refractory materials in carbonizing practice. A. H. MIDDLETON. *Colliery Guardian* **131**, 160-1 (1926).—A general discussion of various materials. Data show that the coking time of coal is reduced almost to 0.5 when semi-silica walls are replaced by silica walls, in consequence of the superior heat cond. of the latter and the higher temp. obtainable. Measurements of the thermal expansion of silica in ovens showed that expansion is almost complete at 600°. On the other hand silica is more sensitive to heat at lower temps. than fireclay or semi-silica, and it is imperative that the rate of heating be slow below 600° and that an even temp. be maintained throughout. When properly used, ground ganister is a satisfactory jointing material for silica constructions.

C. C. DAVIS

Low-temperature carbonization. A. GUISELIN. *Matières grasses* **16**, 6941-6 (1924).—Crit. analysis of Sainte-Claire Deville's work (*C. A.* **20**, 490).

A. P. C.

Successful purification of natural gas at Fort Alma, Ontario. VICTOR LAURISTON. *Can. Chem. Met.* **10**, 30 (1926).—A brief description of a plant (Union Natural Gas Co.) using the Seaboard liquid purification process to remove H_2S from natural gas.

W. B. PLUMMER

Carbonization of Canadian fuels. I. Application of the principles of high- and low-temperature carbonization to wood, peat, and different classes of Canadian fuels. R. E. GILMORE. *Can. Chem. Met.* **10**, 31-4 (1926).—A general review and economic discussion.

W. B. PLUMMER

Carbonization of coal. F. SCHÜTZ AND W. BUSCHMANN. *Stahl u. Eisen* **45**, 1232-42 (1925).—A comprehensive survey of the field for low-temp. carbonization and the com. possibilities of the products obtained, based on a three-years' operation of a rotary retort of the "Fellner & Ziegler" type. The types of fuel suitable for low-temp. carbonization are described, and the yields and characters of the various products discussed in detail. The heavier gaseous hydrocarbons and the light oils are recovered from the gas by a compression method similar to that used in the U. S. A. for gasoline recovery from natural gas. By compressing to about 50 atm. and then expanding to atm. pressure a light spirit ("Gasol") is recovered, a sample of which contained 53.3% of paraffin hydrocarbons (ethane to pentane), 12.2% of ethylene, 16.5% of propylene, 12.2% of butylene, 2.2% of butadiene, 1.5% of amylene, and 2.1% of pentadiene.

B. C. A.

Bituminous coal in water-gas making. W. C. SMYTHIE. *Am. Gas J.* **124**, 90 (1926).—A brief discussion of the method of caleb. the most economical % of blow run in the cycle, as detd. by the economic balance between increasing oil consumption and decreasing fuel/M with increasing length of blow run. In the given case a 14-sec. blow run (4% of the cycle) was most economical.

W. B. PLUMMER

Progressive regional carbonization of coals. DAVID WHITE. *Trans. Am. Inst. Mining Met. Eng.* **71**, 253-81 (1925).—A detailed discussion of the mechanism of the evolution of coals by carbonization (bituminization) and of the factors causing and controlling such changes. Characteristics of the various North American coal fields are discussed and their relation to the general geological history of the various parts of the continent is shown.

W. B. PLUMMER

Desulfurization of large quantities of gas. A. THAU. *Gas u. Wasserfach* **69**, 125-8 (1926).—A discussion of the (German) costs of various types of large-scale installations.

W. B. PLUMMER

Determination of the cubical expansion coefficients of pitches and asphalts. H. MALLISON, F. JACOBSON AND K. SARRE. *Z. angew. Chem.* **39**, 164 (1926).—The coeff. of cubical expansion, 15-60° range, of coal tar pitch (m. 75°, Krämer and Sarnow method) and of a petroleum asphalt (m. 81°, same method) have been pycnometrically detd. as 0.00045 and 0.00062, resp. As a check on the exptl. procedure the coeff.

(20–60° range) for Hg was detd. as 0.000176 as compared to the accepted value of 0.000182.

W. B. PLUMMER

Distinction between lignite- and coal-tar oil. ANON. *Mill. Materialprüfungsamt* **42**, 67(1924).—Valenta's test for distinguishing between lignite- and coal-tar oils, in which the oil is shaken with $1\frac{1}{2}$ times its vol. of dimethyl sulfate, coal-tar oil being completely sol. and lignite-tar oil usually only slightly sol. in this solvent, is not always satisfactory, as creosote oil derived from lignite tar dissolves to the extent of about 80%. Other values, especially the d. and I value, must, therefore, be taken into consideration in judging the source of tar oils.

B. C. A.

Continuous distillation of coal tar. ANON. *Ind. Chemist* **2**, 65–74(1926).—The plant and process at the Silvertown Works of Messrs. Burt Boulton & Haywood, Ltd. are described.

E. H.

Tar-distilling plant at a steel works. ANON. *Engineer* **141**, 68–9; 72(1926).—An illustrated account is given of a plant for distg. tar. One of its outstanding modern features is a continuous tar still unit which shows little signs of requiring renewal after 8 months' operation.

D. B. DILL

Preliminary decomposition of fuels and utilization of the resultant semi-coke. EDMOND MARCOTTE. *Rev. sci.* **63**, 684–9(1925).—Discussion of the possibility of using semi-coke for the production of lean gas in gas producers on motor vehicles.

A. P. C.

Use of metallurgical coke for domestic heating. J. DE THY. *Rev. ind. minérale* **1926**, 69–73.—Proper manipulation of a coke not too high in S will insure uniform and satisfactory heating with an economy of heating 25% greater than with English or Belgian anthracite. Difficulties such as a tendency of the coke to corrode the grate and linings and to form a fusible ash apply only to cokes which are unusually high in S.

C. C. DAVIS

The production of Durham coke, with special reference to the Becker oven. H. W. SMITH AND D. RIDER. *Colliery Guardian* **131**, 443–4(1926).—A review and discussion of the carbonization of Durham coal in the Becker oven, including the characteristics of the latter and its present status both in English and American practice.

C. C. DAVIS

What is "coke combustibility"? R. H. SWEETSER. *Iron Age* **117**, 477–8(1926).—Reviews various work on, and discussions of, coke combustibility and emphasizes the lack of any basis for comparison between lab. tests and blast furnace results.

W. B. PLUMMER

Coal in relation to coke. E. C. JEFFREY. *Trans. Am. Inst. Mining Met. Eng.* **71**, 149–64(1925); cf. *C. A.* **18**, 458.—A discussion, with 13 macro- and microphotographs, intended to show that the coking power of coal is contingent upon a high content of modified wood (Anthraxylon).

W. B. PLUMMER

Ignition point and reactivity of coke products. KARL BUNTE. *Z. anorg. Chem.* **39**, 132–8(1926).—A review of B.'s work on ignition temps. and reactivity of coke with O or CO₂ (cf. *C. A.* **17**, 335, 3915, **18**, 3109), with tables and curves presenting data in some detail. The interrelation of these properties is shown by the fact that if for various cokes the temp. required to give various concns. of CO (in the standard test with CO₂) be plotted against the ignition temp. of the cokes, lines drawn through points of equal CO percentages form a family of parallel curves.

W. B. PLUMMER

Effect of over-heating on the reactivity of coke. C. HOLTHAUS. *Stahl u. Eisen* **45**, 1131–3(1925).—The reactivity of fully carbonized coke is not affected by further heating, but in a semi-coke from which the volatile matter has not been completely expelled, further heating lowers the combustibility and raises the ignition point. Expts. in which semi-coke was heated showed that at the point where the total gas evolution becomes a max., the sp. gr. and ignition point of the coke reach a max., and the combustibility a min.; further heating has no effect, and this point therefore marks the period of effective carbonization.

B. C. A.

Determination of water in hydrocarbon oils, shales and lignite (WOOD, NEALE) 22. Bituminous emulsions for use in fuel briquets (*Brit.* **236**, 641) **22**. Conversion of lignified plant matter into coal. **III.** Sugar formation as an intermediate stage of coal formation (SCHWALBE, SCHEPP) **10**.

ENGEL, W.: *Die Separation von Feuerungsrückständen und ihre Wirtschaftlichkeit, einschliesslich der Briquetierung und Schlackensteinherstellung*. Berlin: Julius Springer. M. 8.10. Reviewed in *Engineering* **121**, 133(1926).

FÜRTH, ARTHUR: *Die Leuchtgasindustrie*. Berlin: de Gruyter & Co. 132 pp. R. M. 1.25.

Fuel mixture. U. VON PORTEN. U. S. 1,572,909, Feb. 16. A fuel for household use comprises manure, garbage or other animal or vegetable refuse 75, a hydrocarbon distillate such as kerosene 2, a combustible binder, *e. g.*, tar oil and pitch 18 and clay 5%.

Fuel briquets. P. E. WELTON. U. S. 1,572,629, Feb. 9. Coal culm is mixed with a binder such as waste sulfite liquor in plastic form and then with a water-proofing material such as asphalt in granular form, shaped and then heated to drive off moisture and liquefy the waterproofing material so that it serves also as a binder.

Fuel briquets. W. PRESCOTT and D. F. WORGER. Brit. 236,636, April 8, 1924. See U. S. 1,554,462 (C. A. 19, 3582).

Fuel for internal-combustion engines. B. H. MORGAN. U. S. 1,572,750, Feb. 9. Gasoline is mixed with about an equal quantity of a mixt. formed of alc. 60-80 and ether 30-60 parts.

Fuels for internal-combustion engines. D. BALACHOWSKY and P. CAIRE. Brit. 236,914, July 12, 1924. Heavy fuels are passed alone or mixed with air over or through heated catalytic or absorbent substances. An app. is described, also adapted for enriching poor or producer gas.

Fuel oil for explosion engines. F. L. DIETZ. U. S. 1,573,307, Feb. 16. A fuel adapted for use in internal-combustion engines comprises low-temp. tar mixed with substances such as EtOH and C_6H_6 to prevent solidification of the tar. U. S. 1,573,307 specifies a fuel for explosion engines consisting of crude tar obtained by the distn. of coal at temps. up to 600° mixed with about 1-3 times its quantity of alc.

Apparatus for carbonizing and compressing bituminous fuels in a rotatable annular series of cells. A. BESTA. U. S. 1,571,927, Feb. 9.

Continuous drying of wooden chips, peat, etc. O. NORDSTROEM and A. MOERCH. Swed. 60,146, Jan. 19, 1926. Mech. features of app.

Gasifying coal. JACKSON RESEARCH CORPORATION. Brit. 236,780, Oct. 13, 1924. In gasifying coal in a vertical retort, the upper part of the retort is heated sufficiently to drive off volatiles and the lower part is heated to incandescence. Gas is withdrawn from the lower end of the retort and returned to the top and passed downwardly through the charge to carry the volatiles into the hotter zone where they are cracked.

Gas from oil and coke. J. RUDE. Brit. 242,029, Sept. 15, 1924. Oil is introduced into coke at the bottom of an externally heated retort and the oil gas produced is removed directly as formed from a point close to the zone of its formation. An app. is described.

Coke and water gas production. KOPPERS CO. Brit. 241,991, July 30, 1924. Steam is diffused into and caused to penetrate the coked sides of the charge without penetrating the uncoked inner portion.

Carburetted water gas. HUMPHREYS AND GLASGOW, LTD. Brit. 242,237, Oct. 31, 1924. In order to obtain a more uniform temp. in a water gas carburetor, steam is not allowed to ext. heat from it, and the down-run gas is led directly to the holder. During the up-run, gas is passed through the carburetor and fixer.

Water gas producer and associated valve-operating devices. HUMPHREYS AND GLASGOW, LTD. Brit. 242,226, Oct. 30, 1924.

Purifying gas house liquor. E. W. KEITH. U. S. 1,573,169, Feb. 16. In purifying gas house liquor for hydrometallurgical use, this solvent menstruum is charged with ZnO in sufficient quantity to react with the NH_4 sulfide present, forming free NH_3 and ZnS and the ZnS ppt. is sepd.

Purifying crude ammoniacal liquor. A. WEINDEL. U. S. 1,571,986, Feb. 9. The liquor is subjected to the action of a solid adsorbent such as Al_2O_3 , $CaCO_3$, sawdust or charcoal for some time to adsorb finely divided particles of tar, and, after removing the adsorbed mass the liquor is treated with a solvent, *e. g.*, C_6H_6 , for recovering the phenols in soln.

Gas producer. K. KOLLER. Brit. 236,725, July 4, 1924.

Gas producers with rotating bodies and ash pans. J. F. ROGERS. U. S. 1,572,040-41, Feb. 9.

Furnace for purifying producer-gas, etc. H. T. GRAFTON, C. W. WEESNER and F. J. HOFFMAN. U. S. 1,572,599, Feb. 9.

Apparatus for cleansing, cooling and mixing producer gas and air for use in internal-combustion engines. R. I. DENHAM and N. C. JONES. Brit. 236,743, Aug. 1, 1924.

Gas calorimeter. R. G. GRISWOLD. U. S. 1,572,283, Feb. 9. Gas is burned in heat-interchanging relation to H_2O proportionate in vol. to the vol. of gas burned.

The gas to be burned is continuously fed by displacing it from a container with the H_2O being heated, and the rise in temp. of the H_2O due to the gas combustion is registered in units indicating the heat value of the gas.

Testing the coking properties of coal. W. J. KLAIBER. U. S. 1,572,391, Feb. 9. See Brit. 221,778 (C. A. 19, 888).

Vertical coke retorts. P. H. DOUGLAS and I. D. THOMAS. U. S. 1,573,145, Feb. 16.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Barnsdall an outstanding name in sixty-five years of history of oil. JAMES MCINTYRE. *Oil & Gas J.* 24, No. 35, 102-3(1926).—Historical. M. BETH HART

Micrographic analysis of mineral oils subjected to certain oxidation tests. VANGHELOVITCH. *Bul. soc. chim. România* 7, 93-9(1925).—Hoblyn's results (*J. Petrol. Tech.* No. 48(1925); cf. C. A. 19, 1048, 1493) are confirmed. In the course of the heat test (heating to 250° till pptn. of asphalt occurs) hard asphalt is first formed, then soft asphalt, and lastly carbene. The heat test can be replaced by a shorter oxidation test, consisting essentially in detg. the min. concn. of a powerful oxidizing agent, e. g., HNO_3 , which will cause sepn. of asphalt, visible under the microscope. The lower the strength of the HNO_3 , the poorer the quality of the oil as a crank-case lubricant.

A. PAPINEAU-COUTURE

A method for the estimation of water in hydrocarbon oils, shales and lignites. C. E. WOOD and A. E. T. NEALE. *J. Inst. Petr. Techn.* 11, 471(1925).—The method is accurate for oils contg. only a small percentage of water. A sufficient quantity of oil to give less than 0.5 cc. of H_2O is distd. with toluene or xylene and 20 cc. of distillate are collected in a graduate tube. Aniline is run into the distillate from a buret until a critical soln. obtained at 20°. The cc. of aniline used corresponds to the amt. of H_2O in the distillate, which may be read off from detd. graphs. M. BETH HART

Cracking heavy petroleum oils at ordinary pressures. L. DAL PRATO. *Bull. fed. ind. chim. Belg.* 4, 16-20, 80-3(1925).—A discussion of the author's (patented) process for vapor-phase cracking at 550-600° over bauxite, Fe_2O_3 , etc., as catalyst. It is claimed that C_6H_6 and cyclohexane and their homologs are present in the gasoline thus produced, and that their presence makes the gasoline miscible (emulsifiable) in com. 95% EtOH for motor fuel. W. B. PLUMMER

The utilization of the aromatic hydrocarbons of petroleum. DAN RADULESCU. *Mon. pétrole Roumain* 24, 1821(1925).—During the World War aromatic hydrocarbons were obtained from Arbanasi petroleum by the following method: The naphtha contg. over 2% hydrocarbons was subjected to a slow rectification. The fraction up to 73° was used as aviation gasoline. The fraction 73-85° contained benzene (95%). The fraction 80-105° contained no aromatic hydrocarbons and the fraction 105-116° contained 23% of toluene. The benzene and toluene fractions were nitrated directly or after further rectification. M. BETH HART

The study of petroleum deposits by means of gas analysis. DOBRESCO. *Mon. pétrole Roumain* 24, 1910(1925).—Analysis of the gas of various wells in Morein showed that a relation exists between the compn. of the gas and the oil bed from which it comes. Gas from the Dacian formation has a high percentage of CO_2 and the corresponding crude is heavy and poor in gasoline. The Metoc formation, however, contains gas with practically no CO_2 and crude rich in gasoline which has a relatively small percentage of paraffin wax. M. BETH HART

Method of calculating energy contained in petroleum gas. S. F. SHAW. *Oil & Gas J.* 24, No. 35, 78(1926).—The ratio between dissolved gas and the quantity theoretically required to raise a gal. of oil is given for several fields. M. BETH HART

Apparatus for the determination of the cold-point of mineral oils by the ether method. ANON. *Chem.-Zig.* 50, 86(1926); 1 cut.—A 3-walled Dewar vessel is closed with a 3-hole stopper. A 15-mm. test tube with thermometer and the oil sample is inserted into the Et_2O bath through the central hole and air is drawn through the Et_2O through tubes in the other holes. A temp. of -35° is easily reached, and 50 cc. Et_2O is enough for 3 detns. J. H. MOORE

The oil shale of Holzheim and the oil produced from it. K. NEUBRONNER. *Petroleum Z.* 22, 57-61(1926).—Carbonization in Al app. gives: carbonization water 5-12,

shale oil 6-7.5, residue 76.8-82%, gas 20-40 l. per kg. The crude oil contains 0.5% org. bases and 1.3% phenols. The yield is very low. Possible utilization of the shale would consist in using the carbonization residue as raw material for cement manu-

M. BETH HART

Oil shale deposits of Salzburg (Germany). EMIL SPORN. *Teer* 24, 86-8(1926).—A stratum has been discovered, about 2.5 m. thick and of considerable extent, the shale contg. 21% bitumen. In an exptl. retort yields were 4-5% (wt.) gases, 9-12% oil, the residue contg. about 6% bitumen.

W. B. PLUMMER

Possibilities of oil shale in event of petroleum shortage. B. MILLS. *Oil Weekly* 39, No. 10, 43(1925).—N and S will be the chief by-products from oil shales. The quantity of oil extd. varies from one gal. to 60 gals. per ton of oil shale. Theoretically it will be possible to recover 25,000,000,000 bbls. of oil from the oil shales of Utah

M. BETH HART

Fire protection and prevention in petroleum industry practice. C. H. HAUPT. *Oil & Gas J.* 24, No. 35, 87-8(1926).—A general discussion. Fire fighting facilities around a refinery include: (a) high-pressure water, (b) steam smothering lines, (c) foam systems, (d) portable extinguishers. Such equipment constitutes an investment of 3 to 5% of the total plant valuation.

M. BETH HART

Paraffin wax content of Grosny petroleum. A. SACHANOV AND N. WASSILJEV. *Neftjanoe i slancevoe Khozjstvo* 8, 44-51(1925).—In detg. the paraffin wax content by Holde's method (cf. Engler and Hofer, "Das Erdöl," IV., 18), a certain quantity of the wax is decomposed during the distn. of the oil or masut, and the decompn. is only inappreciable when the wax content is less than 2%. The distd. portion of masut contg. 13.04% of wax, contains only 8.35%. The rate of distn. has a marked influence upon the extent of the decompn.; thus, with rapid distn., results are 30-50% higher than with slow distn., and as it is very difficult to regulate the rate, the method gives erratic as well as inaccurate results. Pptn. of the wax by the addn. of alc.-ether or alc.-amyl alc. mixts., without previous distn., gives results up to 400% too high, even if resinous constituents are adsorbed by silica gel before pptn. In contrast to Holde's method, however, the method yields more accurate results when the wax content is high. More accurate results are obtained by pptg. the wax with an alc.-amyl alc. mixt. and subsequently re-pptg. it with an alc.-ether mixt. The m. p. of the wax is affected to only a slight extent by impurities, and consequently is of little value in judging the purity; thus, 10% of cylinder oil lowers the m. p. from 57.2° to 56.1°, 9.6% of machine oil to 56.0°, and 50% of oil to 48.6-49.5°. The solidifying temps. of samples of masut from Grosny petroleum contg. 0.1-0.7%, 1.5-2.5% and above 3% of wax, were below -10°, 5° to 20°, and about 30°, resp.

B. C. A.

Control of pressure to increase recovery. H. L. DOHERTY. *Oil & Gas J.* 24, No. 35, 90, 138-40(1926).—Oil underground in an undisturbed pool is in a different condition from the oil after it is placed in tanks. Surface tension and viscosity of the oil are lowered by the gas dissolved in it and render the oil underground more fluid. Data given show the amt. of probable gas pressure at different levels and the method of calcn.

M. BETH HART

Expander increases yield of Pure Oil Plant. R. MUNSELL. *Refiner and Natural Gasoline Mfr.* 4, No. 12, 17(1925).—The output of the compression gasoline was increased 25% by subjecting the compressed gas to a temp. of 28° to 30° F. The low temp. is obtained by the use of an expander-compressor, which operates on the pressure of the dry gas leaving the pressure accumulating tanks at approx. 250 lbs.

M. BETH HART

An electrical apparatus for locating the source of water in oil wells. R. L. KEYES. *Summary of Operations in Calif. Oil Fields.* 10, No. 12, 5(1925).—An app. is described which is used to det. the point of entry of water into an oil well by means of elec. resistance measurements. The fluid in the hole is first entirely displaced with surface water having a relatively low salt content and, therefore, a high resistance. Some of the water is then removed by bailing, thereby reducing the hydrostatic head and allowing the formation fluids to enter the well. The sp. resistance of the fluid is measured at various depths. A marked decrease in the resistance of the fluid is observed opposite the point at which salt water is entering the well. Oil entering, will be indicated by an increase in resistance.

M. BETH HART

Refineries with cracking. C. O. WILSON. *Oil & Gas J.* 24, No. 28, 68(1925).—Refineries with cracking equipment handle 75% of the crude oil.

M. BETH HART

Mechanical entrainment in refining equipment and its elimination. G. M. KIRKPATRICK. *Oil Trade* 17, No. 1, 21(1926).—The use of vapor-pressure tanks and oil and gas separators prevents the entrainment of mist. By this all of the oil is conserved

and also the lighter ends are held back. As a result, the oil tests at the highest possible gravity.

The refinery factor for approximating refinery yields. J. M. EVANS. *Petr. World* 10, No. 10, 52(1925).—A method for detn. is described. Examples are given.

M. BETH HART

Sulfurous acid as a refining agent. ISMAR GINSBERG. *Refr. & Nat. Gasoline Mfr.* 4, No. 11, 16(1925).—Although SO_2 dissolves a greater part of the aromatic compds. of light oil, it is best to subject the oil that is to be refined to further treatment with a small quantity of H_2SO_4 and oleum. When SO_2 is not used, a large amt. of H_2SO_4 is necessary with products which contain a high proportion of S because the acid must first combine with the aromatic and unsaturated compds. in the distillates before it reacts with the sulfur impurities.

M. BETH HART

Refinery gasoline reclaiming plant pays for itself three times in a year. J. C. CHATFIELD. *Nat. Petr. News* 17, No. 48, 27(1925).—The small oil absorption plant of the Johnson Oil and Refining Co. is described. Uncondensed still vapors and vapors from the Dubbs cracking plant are reclaimed.

M. BETH HART

Gasoline recovered in one operation. GEORGE W. H. REID. *Oil & Gas J.* 24, No. 35, 125, 127(1926).

M. BETH HART

Economic aspect of cracked gasoline. R. B. DAY. *Oil & Gas J.* 24, No. 27, 66(1925).—A general discussion which emphasizes the need for max. recovery of motor fuel oil and suggests the importance of chem. research.

M. BETH HART

Training school at gasoline plant. T. N. S. HILL. *Oil & Gas J.* 24, No. 25, 149(1925).—Description of training school at the Pacific Gasoline Plant

M. B. H.

Some of the potential public health hazards from the use of ethyl gasoline. F. B. FLINN. *J. Ind. Hyg.* 8, 51–66(1926).—Careful physiol. expts. with rabbits, guinea pigs, rats, goats, pigeons and monkeys to det. the possible hazard due to contact with coned. PbEt_4 , splashing with Et gasoline, and inhalation of Et gasoline fumes prove that storage of Pb takes place under sufficient exposure, and this storage of Pb in the body constitutes potential Pb poisoning. The rate of excretion did not equal the rate of absorption in these expts. Absorption through the skin was proven by application of 0.1% PbEt_4 in gasoline in repeated doses of 0.3 cc. to rabbits, 0.1 cc. to guinea pigs, and 2 cc. to goats. Absorption of Pb from Et gasoline fumes was proven by causing the animals to inhale air contg. about 0.04 mg. Pb per cu. ft. (1.4 mg. Pb per cu. m.); and by exposure to fumes rising from the natural evapn. of Et gasoline. When 0.01 cc. coned. PbEt_4 was applied daily to 5 rabbits, death ensued in 13 to 19 days. C. M. S.

Lubricating oils. W. C. LUCKOW. *Baking Tech.* 5, 40–2(1926).—Routine tests for oils are given and the analytical results of over 50 oils are tabulated. Most of the oils tested were for automobile use.

RUTH BUCHANAN

Evaluating lubricating oils. ISMAR GINSBERG. *Refiner and Natural Gasoline Mfr.* 4, No. 12, 19(1925).—A good lubricating oil must have a certain amt. of "oiliness" or lubricating power. It must be stable from a phys. and chem. standpoint. It must possess a certain degree of viscosity. Oiliness is connected with the static friction. The change of viscosity with the temp., the volatility and the solidification point det. the physical behavior of the oil. The Conradson coking test and the oxidation or sludging test are characteristic of chem. behavior.

M. BETH HART

Contact filtering of lubricating oil successful at Ohio refinery. P. TRUESDELL. *Nat. Petr. News* 17, No. 47, 78(1925).—Lubricating oil is filtered through fuller's earth of 200 mesh, untreated and unroasted. The charge consists of 125 bbls. of oil and 1400 lbs. of earth.

M. BETH HART

Effect of moisture and temperature on the power factor of transformer oil. J. E. SHRADER. *J. Frank. Inst.* 199, 513–38(1925); *Science Abstracts* 28B, 337.—Four methods usually employed in making dielec.-loss measurements are described. The fact that there is a decreased absorption of moisture at the higher temp. for reheated oil would suggest that the oil had undergone some chem. change such that its water soly. was different at the higher temp. The results show that the power factor shows a min. value with voltage and the increase in power factor on the upper range of voltage is not very marked for oil in good condition; moisture mechanically mixed with oil settles out from the oil as shown by the decrease in losses and power factor; moisture is driven from oil by heating.

H. C.

Charcoal. HILDING BERGSTROEM AND SVEN LUNDIN. *Jernkontorets Annaler* 109, 625–38(1925).—Results are given of investigations regarding the influence of the final carbonization temp. on the yield of charcoal, the compn. of the product, the yield of distillate and uncondensable gas, and the compn. of the latter, with several tables curves and illustrations of the app. used. The investigations include also the increase

in wt. of charcoal in H_2O -sadt. air and the activation of charcoal for decolorizing purposes by means of heating in H_2O -vapor. C. A. ROBAX

The composition of rosin oils from Bukowina pines. OSCAR CZERNY. *Bul. soc. chim. România* 7, 91-2(1925).—Resinic acids extd. from pine oil by means of Na_2CO_3 , and pptd. with H_2SO_4 , recrystd. from EtOH give rhombohedral plates of abietic acid, m. 156° . The purified oil gives the Storch-Norawski reaction (violet color with C_6H_6 , Ac_2O and a few drops of $SnCl_4$). Pine oil treated with KOH at $50-60^\circ$ for 24 hrs., washed and dried, gave a clear, yellow, odorless oil, free from fluorescence, with practically no acidity or sapon. no., and I no. 47.5. Most of it distd. (in the presence of Na) at $250-350^\circ$, and no solids could be sepd. by cooling the distillate, in a mixt. of CO_2 -snow and Me_2CO . Fractional distn. under a pressure of 9 mm. gave the following fractions: (1) $195-8^\circ$, colorless oil without fluorescence, d_{15} 0.9647, with compn. corresponding to octahydrotene, $C_{18}H_{36}$, identified by production of trimellitic acid, $C_6H_6O_6$, m. $225-6^\circ$, by oxidizing with $HNO_3-H_2SO_4$ on the water bath for 24 hrs. followed by sapon. with KOH. (2) $240-65^\circ$, colorless, odorless oil, free from fluorescence, d_{15} 0.960, with compn. corresponding to styrene, C_8H_8 , identified by its dibromide, m. 74.5° . (3) $310-40^\circ$, slightly bluish oil, most of which distils at $310-5^\circ$, with compn. corresponding approx. to C_6H_4 . (4) $340-8^\circ$, greenish oil with aromatic odor, d_{15} 0.9686, from which concd. H_2SO_4 exts. a colorless oil, d_{15} 0.9686, with compn. corresponding to diterphenyl, $C_{20}H_{20}$, identified by its yellow nitrate, $C_{20}H_{17}(NO_2)_3$; the residue from the H_2SO_4 extn. on heating *via* Renard gave an oil m. $392-3.4^\circ$, with compn. corresponding to retene, $C_{18}H_{18}$, identified by its picrate, m. 125° . A. PAPINEAU-COUTURE

Relation of oil shale to petroleum (VAN TUYL, BLACKBURN) 8. $CaCl_2$ waters from certain oil fields in California (HUDSON, TALIAFERRO) 8. Kerogen and its relation to the origin of oil (FRAGER) 8. Analyses of Wyoming oil-field waters (ESTABROOK) 8. Water analyses in oil production and some analyses from Poison Spider, Wyoming (PARKS) 8. Heat-exchange system for fractional condensation of oil vapors (U. S. pat. 1,573,129) 13.

HICKS, J. H.: The Laboratory Book of Mineral Oil Testing. 4th Ed. revised by A. W. Cox. London: Chocless Griffin & Co., Ltd. 128 pp. Cloth 5s. Reviewed in *Chem. News* 132, 61(1926).

PATEK, FRANZ: Holz-Lexikon. Ein Hilfsb. f. d. Holzfachmann. Berlin: C. A. Schwetschke & Sohn. R. M. 10.

Distilling petroleum oils. J. M. WADSWORTH. U. S. 1,572,584, Feb. 9. Crude petroleum or other oil is subjected to repeated vaporizing operations, fractions of similar b. p. are combined and condensed to form primary distillates of varying volatility, and these primary distillates are continuously redistd. as sep. substances, and the residue from the substances of lighter distillates are added in series to the substances of heavier distillates.

Cracking hydrocarbon oils. H. WOLF. Brit. 242,223, Nov. 3, 1924. After cracking oil by heating under pressure to above 390° (e. g., in a heated coil or metal bath), the products are cooled below 250° (preferably to $100-150^\circ$) immediately on expansion by admixt. with cooled residual products, reflux condensate or crude oil. The cracked product may, for this purpose, issue into a vessel contg. oil and Raschig rings.

"Constructive conversion" of liquid hydrocarbon oils. H. R. BERRY. U. S. 1,571,994, Feb. 9. Hot H-contg. gas, e. g., water gas, and liquid hydrocarbon material such as a petroleum oil are caused to counter-flow in intimate contact, e. g., in an app somewhat like a column still, so that the liquid hydrocarbons are constantly subjected to an increasing temp. and the H-contg. gas is constantly subjected to a decreasing temp. The conditions of heat and pressure are regulated so that part of the liquid hydrocarbon combines with the H-contg. gas and liquid of lower and gas of heavier gravity are produced. An app. is described.

Demulsifying mineral oils. W. D. LEEPER. U. S. 1,573,321, Feb. 16. The oil is first washed by passing it in finely divided state through hot H_2O , and live steam is then passed through the washed oil.

Oil and other products from bituminous materials. PATENTAKTIEBOLAGET GROEN-DAHL-RAMÉN. Swed. 60,119, Jan. 19, 1926. Mech. features of app.

Internally heated annular cellular retort for transforming and distilling hydrocarbon oils. A. A. F. M. SIEGLE. U. S. 1,572,691, Feb. 9.

Still, dephlegmator, separator, etc., for distilling and refining petroleum oils. W. C. AVERILL, JR. U. S. 1,573,025, Feb. 16.

Condensing vapors from oil pressure stills. E. W. ISOM and J. E. BELL. U. S. 1,573,167, Feb. 16. A stream of condensate is circulated to and from a relatively large body of the condensate and vapors from a pressure still are injected into this circulating stream between a cooler through which it passes and the large body of condensate.

Fractionating column and other apparatus for producing gasoline. F. TINKER. U. S. 1,572,626, Feb. 9.

Separating wax from mineral oil distillates. S. H. HALL and C. H. HAPGOOD. U. S. 1,571,943, Feb. 9. A wax distillate soln. is refrigerated to throw the wax out of soln. in cryst. form and the mixt. is centrifuged while feeding H_2O at a temp. sufficient to melt the wax to the periphery of the mixt. undergoing centrifugation to facilitate sepn.

Reconditioning used lubricating oils. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 242,272, Oct. 29, 1924. Oils such as those from internal-combustion engines, which contain suspended solids, are treated with an alkali silicate or other weakly basic agglomerating substance sol. in H_2O , sludge is sepd. with H_2O and volatile impurities are distd. An app. is described.

Hydrocarbon lubricating oils. J. C. BLACK. U. S. 1,572,465, Feb. 9. After treating hydrocarbon oil with H_2SO_4 and sepn. of the pptd. acid products, the oil is treated with neutralizing and decolorizing material, heated, and sepd. from the added purifying and decolorizing substances.

Bituminous emulsions for use in road-making or in fuel briquets, for coating stone, roofing, etc. H. A. MACKAY. Brit. 236,641, April 8, 1924. Sulfonated fatty oils are used in prepg. emulsions of Mexican asphalt, pitch or other bituminous substances. Cf. C. A. 20, 663, 811.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Reply to the remarks of K. Hess on the depolymerization of cellulose. F. HEUSER AND N. HIEMER. Z. *Elektrochem.* 32, 47-50(1926); cf. C. A. 18, 1384; 20, 110.—In reply to Hess (C. A. 20, 663) the authors maintain that the Cu values 6.8-8.5 obtained for hydrocellulose indicate a pure product. Impurities are further reduced by methylation. After prepn. of a hydrocellulose from viscose fibers, the product was found to have a Cu value of 10.4 by Schwalbe's method, but only 6.97 by the method of Weltzien and Nakamura. The ash-free substance was methylated, washed, and filtrate and wash water were examd. for impurities. The latter proved to be simple sugars; hence it is safe to assume that degradation products are removed in washing. The mean mol. wt. of the methylated product is 2200. Whether mol. wts. of methylated celluloses may be detd. accurately by f. p. methods, was investigated by making the detn. on a pure hydrocellulose, Cu value 0.45 (1.84 by Schwalbe's method). The value found was 1900, which shows that accurate results can be obtained by taking great care in the readings. So detd., the mol. wt. represents the size of the phys. mol. in colloidal soln.

Bleaching pulp in vacuum with hypochlorite. RAFFAELE SANSONE. *Papeterie* 48, 21-5(1926).—Brief description of an app. allowing of bleaching in vacuum, with an outline of its operation and advantages.

Increasing the combustibility of cigaret paper. ANON. *Papeterie* 48, 18, 21 (1926).—It is suggested that a small quantity of cellulose chlorate or nitrate be added to the stock in the beater, a short time before dropping. A method of prepn. of these esters is described.

The combustibility of cigaret papers. H. FREYDIER. *Industrie papetière* 5, 19 (1926).—Brief outline of the methods which can be used to impart the desired degree of combustibility to cigaret papers.

Paper fillers. M. B. SHAW AND G. W. BICKING. *Bur. Standards, Tech. Paper* 301, 733-48(1925); *Pulp Paper Mag. Can.* 24, 153-9(1926); *Paper Trade J.* 82, No. 3, 46(1926); cf. C. A. 19, 576.—Runs of book paper using 10-20% of different fillers were made, and the product was examd. as to retention, color, strength, opacity, etc. Asbestine and talc have approx. the same paper-making properties and are comparable to the better clays. Crown filler and gypsum have relatively low retentive qualities when the usual machine water system is employed, and the fillers are added in the usual amts. The comparatively small quantities of filler in finished paper are not

sufficient to produce variations attributable to the color characteristics of the fillers employed, unless pronounced differences in color are evident in the filling materials. Sizing and other paper-making operations were not adversely affected by any of the materials. Differences in opacity, finish, strength and degree of sizing were due chiefly to differences in retention of the fillers. Bibliography of 25 references. A. P.-C.

Wood from the Ivory Coast. F. HEIM DE BALSAC, M. CERCELET, G. S. DAGANI AND R. HEIM DE BALSAC. *Bull. agence gén. colonies* 18, 520(1925); *Bull. Imp. Inst.* 23, 482(1925); cf. C. A. 20, 285.—"Avodiré" wood (*Turroeanthus africana*, F. Pelligrini) having ash 4.56, fats and waxes 0.80, cellulose 62.15, lignone 32.49% (all on the dry basis), on digestion with NaOH at 5% concn. for 8 hrs. under 3 kg. pressure, gave a light brownish yellow pulp, which bleached easily, yielding 37% of bleached pulp. On microscopical examn it was found to consist almost entirely of cylindrical fibers which tapered regularly and had a wide lumen and thin walls; a few cells and fragments of vessels were also present. The fiber length was 1-2 mm. (av. 1.5), and the diam. 0.015-0.025 mm. (av. 0.020). The pulp furnishes paper which is comparable in all respects with that obtained from the ordinary com. wood pulps. A. P.-C.

The composition of lignin. L. P. ZHEREBOV. *Bumazhnaia Promyshlennost* 3, 495-506, 686-709(1921); *Paper Trade J.* 81, No. 27, 47-58(1925). A crit. review. A. PAPINEAU-COUTURE

Production of paper and cardboard from peat. A. LAMIRETTE. *Papeterie* 47, 809-13, 901-5, 950-5, 990-4, 1052-5, 1090-4, 1134-8(1925).—More particulars are given concerning L.'s previously published work (C. A. 17, 2503), more particularly as regards differences in treatment necessitated by considerable variations in the properties of peat of different origins. L. considers that some of the results obtained might justify com. operations, but this has not yet been realized as the processes can hardly be worked successfully under present economic conditions. A. PAPINEAU-COUTURE

Reddening of sulfite pulp. ANON. *Mon. papeterie belge* 6, 97, 99(1926).—The reddening of sulfite is attributed to formation of free S towards the end of the cook, which, under the action of traces of H_2S , forms a white or yellowish compd. with the lignin in the pulp; and this compd. under the action of oxidizing agents, gives a red coloration. A. PAPINEAU-COUTURE

Treatment of straw and of resinous woods with sodium sulfite and ammonium sulfite. M. V. BROT AND M. HIRSCHL. *Papier* 29, 75-80(1926); cf. Brot and Men, C. A. 19, 1052.—Tests were carried out in the same app. and under the same conditions as those previously reported. Comparative expts. with NaOH and Na_2SO_3 gave the following results:

Wt. of chemical per 100 g. dry straw	10	20	30	40
Yield obtained with NaOH	54.1	44.3	41.0	39.2
Yield obtained with Na_2SO_3	61.0	57.5	54.0	52.5

The color of the Na_2SO_3 pulp was much whiter than that of the NaOH pulp. Similar results were obtained with $(NH_4)_2SO_3$. On treating Bordeaux pine contg. 6-8% resin with 60% of $(NH_4)_2SO_3$ (on the wt. of dry wood), at 180-5°, delignification takes place suddenly between the 3rd and 5th hrs. of cooking. The pulp obtained in 4 hrs. bleaches easily. Under the microscope it has a normal appearance, but still contains an appreciable amt. of resin. The advantages of such a process over the soda and sulfate processes are discussed, and the problem of waste liquor recovery is also discussed as regards both the Na and NH_4 sulfite treatments. A. PAPINEAU-COUTURE

Fresh digester filler. W. G. MACNAUGHTON. *Paper Trade J.* 82, No. 5, 61(1926).—The equipment consists of a fan which circulates air with considerable velocity through the digester while it is being filled with chips. Tests at the Robertsfors mill (Sweden) showed an increase in yield from 78 to 108 kg. of air-dry (90%) pulp per cu. m. of digester space. A. PAPINEAU-COUTURE

Heat problems in the sulfate mill. K. M. THORSEN. *Paper Trade J.* 82, No. 5, 62-5(1926).—Comparison of the usual recovery system in sulfate mills with the Sandberg-Sundblad system, showing the advantages of the latter. A. P. C.

Mechanical pulp and its physical property of wetness. J. H. MOWAT. *World's Paper Trade Rev.* 84, 1988-96(1925); *Paper Maker & Brit. Paper Trade J.* 71, 59-62(1926).—Discussion of the importance of wetness (or freeness) of groundwood in the manuf. of news print, and of the characteristics of the pulp according to its process of manuf. and condition on reaching the paper mill. A. PAPINEAU-COUTURE

The freeness test for sulfite and groundwood pulp. FREDERICK BARNES. *Pulp Paper Mag. Can.* 24, 105-7, 123(1926).—Efforts were made to develop a freeness tester (of the Schopper-Riegler type) of the highest accuracy and widest range possible, the

time-sedimentation tester ("slowness" tester) being used as a comparative standard. Results obtained indicate that a depth of stock increased by 50% would give the Green tester considerably closer side-drainage figures and an improved range. Interesting results were obtained by applying a strong suction to the whole base of the freeness tester, giving an even curve when plotted against the time-sedimentation test. When groundwood contains a large no. of fiber-aggregates, the freeness tester may give results which are misleading as to the quality of the stock, and the slowness tester is preferable in that case.

The testing, analytical and research laboratories of the French School of Paper Making. ANON. *Industrie papetière* 4, 374-6(1925); 5, 15-9(1926).—Description of the labs. and their equipment, with a list of the principal researches carried out from 1907 to 1925.

Electric oven for determining the moisture content of pulp, designed at the French School of Paper Making, Grenoble. M. ARIERT AND M. FALLOT. *Papier* 28, 1303-5 (1925).—The oven can hold 50 or more samples in perforated Al baskets. The balance pan is inside the oven, and the samples can be weighed without having to open the oven.

Control of operations in the pulp mill. R. DIECKMANN. *Papier Ind.* 7, 1606-7 (1926).—See C. A. 19, 2563.

SIEBER, RUDOLF Ueber das wärmetechnische Verhalten des Sulfitzellstoff-Kochprozesses. Biberach-Riss, Württemberg: Gfintter-Staib Verlag. M. 6.50. Reviewed in *Pulp Paper Mag. Can.* 24, 162(1926).

Drying newly formed traveling webs of paper. E. A. BRINER and H. J. GUILD. U. S. 1,573,297, Feb. 16. Mech. features of regulating the constraint under which the web is held during different successive stages of drying.

Transparent paper. C. E. SWETT. U. S. 1,571,976, Feb. 9. Glassine paper is treated with a soln. of tannic acid in alc. or other non-aq. solvent, to render it transparent. Terpinol hydrate also may be added. Cf. C. A. 20, 823.

Reclaiming used paper. G. HAMMOND. U. S. 1,572,478, Feb. 9. Paper carrying pigment is heated at a temp. somewhat below 43°, beaten and treated with caustic alkali during the beating. An alkali acid sulfite such as NaHSO₃ is then mixed with the pulp at substantially room temp. and further beaten.

Deinking paper. G. HAMMOND. U. S. 1,572,479, Feb. 9. A compn. for deinking paper is formed of H₂O, glucose and "naphtha" soap.

Paper-making apparatus. G. F. McCCLAY and H. V. HAIGHT. U. S. 1,572,498, Feb. 9.

Blended color wall paper. J. J. WARREN. U. S. 1,573,208, Feb. 16. A color soln. is applied to a blended pulp stock as it flows over an inclined apron.

Pulp from bagasse and similar material. E. C. LATHROP and T. B. MUNROE. U. S. 1,572,539, Feb. 9. Bagasse or similar fibrous material is fermented to soften and heat the material and is piled in masses which will retain heat on their interior sufficiently to lessen their moisture contents and effect substantial sterilization. U. S. 1,572,540 specifies preserving green bagasse and similar material from injurious fermentation during storage by substantially satg. a mass of the material with moisture and keeping the mass sufficiently wet to maintain a fermentation by lactic and similar bacteria while inhibiting other fermentations until a sufficient proportion of the parenchymatous matter is destroyed.

Pulp from wood chips or similar material. L. BRADLEY and E. P. McKEEFE. U. S. 1,572,840, Feb. 9. A cooking liquor is used contg. Na₂S₂O₃ and a quantity of NaOH in excess of that required to decompose silicates and aluminates in the material treated.

Apparatus for cooking wood chips to form pulp. J. T. JAEGER. U. S. 1,572,723, Feb. 9.

Cellulose acetate films. S. J. CARROLL. U. S. 1,572,232, Feb. 9. Transparent cellulose acetate films contain sufficient tributyrin (usually about 10-35%) to maintain flexibility even after prolonged heating at 65°. Cf. C. A. 20, 111.

Cellulose ester lacquers. R. A. BEAUSEJOUR. U. S. 1,572,461, Feb. 9. A layer of cellulose ester lacquer is floated on an aq. NaCl soln. or other liquid of greater d. with which the lacquer is substantially immiscible. A wood panel or other article to be lacquered is then dipped through the floating layer of lacquer.

Filaments and films from cellulose xanthates. H. HAWLIK. Brit. 242,240, Oct. 29, 1924. Insol. water-proofing compds. are formed in filaments or films during the spinning or like operation, by chem. reaction; e. g., a sol. salt of Al, Ba, Ca, Sr, Sn or Zn may be incorporated with the viscose soln. and a higher fatty acid with the "spinning bath" or pptg. soln. Brit. 242,242 specifies the addn. of sol. sulfides (or formation of sulfides from oxides) in making films, filaments, etc., from viscose.

Reducing viscosity characteristics of nitrocellulose. L. E. BRANCHEN. U. S. 1,572,266, Feb. 9. Nitrocellulose is first softened with MeOH (contg. H₂O) or other penetrant liquid and is then separately treated with an aq. soln. of an alkali, e. g., a 2% Na₂CO₃ soln. contg. Cl (for 1-3 days at room temp.).

Reducing viscosity characteristics of nitrocellulose. S. E. SHEPPARD and L. W. EBERLIN. U. S. 1,572,248, Feb. 9. Nitrocellulose is treated with a substantially non-nitrating gaseous mixt. contg. higher oxides of N, e. g., NO and NO₂. U. S. 1,572,249 specifies treating nitrocellulose with a bath of H₂O₂ or other peroxide, for the same purpose.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

The manufacture of nitrocellulose. A. B. NIXON. *Hercules Mixer* 8, 55-7 (1926).—A description of the manuf. of cellulose nitrates from cotton linters based on practical experience, and giving detailed information on cutting and grading linters, and the factory control.

CHARLES E. MUNROE

Experimental researches on the explosive and the shock waves. P. LAFFITTE. *Ann. phys.* 4, 587-694 (1925).—This is a detailed review of the results of L.'s previous work on detonating gaseous mixts. (cf. C. A. 18, 1910; 19, 1776) with additional matter dealing with the formation and propagation of plane detonation waves, special attention being given to the influence of the diam. of the tube in which the explosion phenomena are propagated on the length over which the combustion wave, which precedes the birth of the detonation wave, extends. This was found to be a function of the increasing diam. of the tube. Where there is an abrupt change in the diams. of the tubes the duration of the period of combustion which succeeds the explosion wave is found to be an increasing function of the relation between the diams. of the tubes. Observations on tubes down to those 0.1 mm. in thickness show that the velocity of the explosion wave is independent of the thickness of the wall of the tube. Studies of the influence of initial temps. up to nearly the temp. of inflammation of detonating mixts. show that the velocity is a slowly decreasing function of the temp. When inflammation is provoked in an explosive gaseous mixt. by a sufficiently powerful detonator a spherical explosion wave is formed and propagated. The development of shock or compression waves by detonating solid explosives has been further studied and while this shock wave has been found initially to have a higher velocity than the detonation wave in the explosive, and to propagate itself to a considerable distance beyond the explosive, its rate falls off very rapidly. The propagation of the shock wave in combustible and incombustible gases, and through solids also was studied as were the spectra of mixed gases in a state of combustion and of these and solid explosives while detonating. L. urges the use of Berthelot's "explosive" wave in place of Dixon's "explosion" wave but he makes "explosive wave" synonymous with detonation wave. C. E. M.

The explosion at 9 Kirchstrasse (Berlin). K. A. HOFMANN. *Gas u. Wasserfach* 69, 154-7 (1926).—This explosion, of unknown origin, was of great violence, tearing out the side and front of the house from the street floor to the roof (four stories). It is presumed that O from CaOCl₂ stored on the first floor formed an explosive mixt. of high brisance with C₂H₄ vapors or C₂H₂ from some source. There was no evidence of leaks of illuminating gas. W. B. PLUMMER

Warning against the customary process of making cooling baths from inflammable compounds and liquid air. H. STAUDINGER. *Z. angew. Chem.* 39, 98 (1926).—From 2 to 2½ cc. of liquid O (old liquid air) placed in a thin dish and mixed with 1 cc. of ether

(added through a tube at least 1 m. long), and then ignited by a spark from wires placed 1 cm. above the liquid, explode with about the force developed by 3 l. of detonating gas or 4 g. of nitroglycerine. Such mixts. are also sensitive to friction and concussion. Diln. with N, or mixt. in other than the optimum concns., diminishes the severity of the explosion. The danger inherent in such mixts., when used for low temp. work, is apparent.

Generation of electricity in fuel pipes. BRUNO MÜLLER. *Apparatebau* 38, 29-30 (1926).—Expts. showed that tensions of 100-1200 v. resulted from forcing benzine through a nozzle.

Corrosion from cotton dyeing and finishing. W. W. CHASE. *Textile World* 69, 1513-5(1926).—The corrosion of buildings and app. by the various textile chemicals is considered and suitable resistance materials are suggested.

CHAS. E. MULLIN

Viscose as a filler. WM. B. NANSON. *Textile World* 69, 585-7(1926).—Cotton piece goods may be filled by printing with a suitable viscose soln., in an ordinary single-color printing machine equipped with a steel finishing roll, instead of wood. The filled cloth is dried and passed through an aniline black aging box at 95-7°. The dried cloth may be softened by means of soap or sol. oil in the dye bath.

CHAS. E. MULLIN

Warp streaks in silks. JAMES CHITTICK. *Textile Am.* 45, No. 2, 47-8(1926).—Causcs. CHAS. E. MULLIN

Tests to distinguish between viscose and cuprammonium artificial silks. O. S. RHODES. *J. Textile Inst.* 17, 75-6T(1926).—A soln. contg. 1% AgNO_3 , 4% $\text{Na}_2\text{S}_2\text{O}_3$ and 4% NaOH is prepd. by dissolving the AgNO_3 and $\text{Na}_2\text{S}_2\text{O}_3$ separately and mixing, the NaOH is then added and the whole brought to the boil and filtered. The 2 silks are separately immersed for 1 min. in the prepd. reagent at boiling, when the cuprammonium silk remains white and the viscose silk turns brown. Nitrate silk also gives a brown coloration with this reagent, but a blue coloration with diphenylamine sulfate. L. W. RIGGS

The chemical analysis of cotton. The ash content and ash alkalinity of typical cottons. R. G. FARGHER AND M. E. PROBERT. *J. Textile Inst.* 17, 46-52T(1926). The mineral matter in the principal cottons of the world varies between 1 and 1.3%. Certain American outside growths and native Indian types show slightly higher figures, while the Sea Island varieties are apt to be lower in mineral matter. The alkyl. per g of ash is a fairly const. factor and is approx. proportional to the ash content, so without much error the ash may be calcd. from the ash alkyl. L. W. RIGGS

Progress in the knowledge of fibrous materials. O. HERZOG. *Ledertech. Rundschau* 18, 30-2(1926); *Z. angew. Chem.* 39, 297-302. I. D. C.

Nature of the proteins of wool. S. R. TROTMAN, E. R. TROTMAN AND R. W. SUTTON. *J. Soc. Chem. Ind.* 45, 20-4T(1926).—Woolen fabric was extd. in a large hot Soxhlet app. successively with light petroleum ether, CCl_4 , CS_2 and alc. when no loss of S occurred. The expts. of Allworden (cf. *C. A.* 10, 1436) were repeated but his results were not confirmed. Cold N or 0.2 N NaOH removed 50% of the S in 12 hrs.; 0.01 N NaOH removed no S. When cold dil. NaOH acts on wool the cortex appears to be attacked more readily than the epithelium. This suggests the presence of 2 proteins. Two proteins were sep'd. from wool by treatment with concd. HCl at 70°, filtering, reprecip. and purifying. The first protein (A) gave ash 0.40%, S 362, N 12.50. The filtrate after removing (A) contained another protein (B) which gave ash 0.10%, S 1.49, N 12.68. A considerable proportion of the S is present in firm combination, but it may be removed without destroying the protein-like structure. (A) and (B) gave humin N 2.55 and 2.45%, amide N 1.20 and 3.90, diamino N 12.00 and 34.30, mono amino N 86.25 and 59.35, resp. L. W. RIGGS

Specific gravity of wool and its relation to swelling and sorption in water and other liquids. A. T. KING. *J. Textile Inst.* 17, 53-67T(1926).—This paper is for the most part purely scientific in character and does not deal directly with mfg. procedure. The topics considered are the effect of sorption on the actual detn. of sp. gr., penetration by solvents and oils, influence of salts on swelling and sorption, and density methods of detg. regain and of estg. wool-cotton mixts. L. W. RIGGS

The moisture relations of cotton. The absorption of water by cottons of various origins. A. R. URQUHART AND A. M. WILLIAMS. *J. Textile Inst.* 17, 38-45T(1926) cf. *C. A.* 19, 2749.—The differences which are observed among raw cottons with reference to water absorption are considerably reduced by the partial purification effected by boiling with water. It is probable that the pure celluloses of these various cottons are only slightly variable, the observed differences being largely attributable to the non-cellulosic impurities. The removal of the non-cellulosic materials is accompanied by a reduction in hygroscopicity. Dyed materials exhibit a further reduction which can not be wholly explained in terms of loading the cotton with non-hygroscopic substances. L. W. RIGGS

Comparison of the effects of oxidation before and after the mercerization of the cotton fiber. EDMUND KNECHT AND E. F. MULLER. *J. Soc. Dyers Colourists* 43, 46-53(1926).—Mercerized yarns are more susceptible to oxidation than plain cotton. The Cu nos. of the products are greater than that of plain oxidized cotton, even when the oxidation has been the same in each case. This increase in Cu nos., after deducting the resp. amts. caused by mercerization, is the same for yarns mercerized with NaOH and HNO_3 at their resp. optimum mercerizing strengths. Mercerizing of oxidized yarn with NaOH produces a tendering and decrease in Cu no., but for degrees of oxidation below "0.0064 atom of O/mol." the effect of mercerization is to increase the strength and raise the Cu no. of the yarn. Yarns mercerized with NaOH and oxidized in a vacuum have a Cu no. identical with that of ordinary cotton oxidized in a vacuum. The aggregate totals of a series of Cu-no. detns. conducted on the same piece of oxidized yarn give an approx. identical value for plain and mercerized cotton. Cotton yarns mercerized by varying strengths of NaOH and then subsequently oxidized, show a decrease in Cu no. which varies with the diminishing strength of the NaOH. There is a pro-

nounced rise in temp. during mercerization with both NaOH and HNO₃. A definite strength of mercerizing soln. is necessary to obtain a completely mercerized yarn. The percentage of moisture retained by a completely mercerized yarn corresponds to the mol. proportion of 2 mols. of cellulose to 1 mol. of water. A semimercerized yarn contains a lower percentage of moisture and possesses less affinity for O than a fully mercerized product. The heat of reaction also is less. These results appear to indicate that moisture-free mercerized yarn loses its affinity for O and that yarn kept moist by phys. methods shows no increased affinity for O. Dyed mercerized yarns fade more readily than ordinary dyed cotton. Yarns mercerized with NaOH show this property to a greater extent than those mercerized with HNO₃. L. W. RIGGS

Mildew in cotton goods. The growth of mold fungi on sizing and finishing materials. I. E. MORRIS. *J. Textile Inst.* 17, 1-22T (1926). Seven species of fungi, all obtained from cotton goods which had mildewed under ordinary trade conditions, were cultivated on size pastes and agar jellies. From these expts. the rate of growth of each fungus was detd. on different sizing and finishing substances, thus giving a basis for classification of these substances according to their degree of liability to mildew. The dextrins and wheat, rice and cassava flours permit the most rapid growth and production of spores. Growth on dextrins tend to fall behind that on flours. An intermediate group is formed by wheat and maize starches, gum tragacanth, and sol. starch. On tapioca flour, sago and farina fungi grew slowly and produced few spores. The greater growth on flours than on starches is attributed to their greater sugar and N content. **Mildew in cotton goods.** The growth of mold fungi on steeped wheat flour. *Ibid* 23-37T.—A period of fermentation decreases the liability of a flour to develop mildew so far as the growth of *Clasosporium* and *Fusarium* are concerned, but has slight effect upon the growth of *Aspergillus* and *Penicillium*. The addn. of 6% ZnCl₂ decreases, in varying degrees according to the species, the liability to mildew. The addn. of NaOH to the steep until it is neutral to litmus increases the liability, which is unaffected by the length of the steeping period. If the steeped flour is washed free of acids the liability is increased, but to a less extent than by neutralization. The effect of adding ZnCl₂ to the steep is removed by washing. L. W. RIGGS

Banana fiber. R. O. BISHOP. *Malayan Agr. J.* 13, 376 81 (1925).—Fiber was prepd. by stripping the stems of *Musa malaccensis*, Ridl., *M. violascens*, Ridl., and cultivated banana, the yield from the latter being smaller, but in quality the fiber resembles the medium grades of "partially cleaned" Manila hemp. Analysis of the fiber gave the following results for the 3 varieties, all on the dry basis except H₂O: H₂O 10.4-12.29, ash 1.47-2.6, water-washing loss 1.8-6.9, acid-washing loss 3.03-9.5, hydrolysis "A" loss 17.7-21.0, hydrolysis "B" loss 25.0-29.3, cellulose 30.7-34.62%; fiber length 0.9-6.30 mm., av. 4.15 mm., mean fiber diam. 0.025 mm. With ZnCl₂ and I the fiber is stained a deep blue, after a transient claret in some parts of the slide; with I it gives a brown color, and with H₂SO₄ and glycerol it gives no color. A. PAPINEAU-COUTURE

Weighting and the dyeing of weighted silk piece goods. C. A. PULLER. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 75-7; *Am. Dyestuff Rept.* 15, 123-5.—An address. L. W. RIGGS

Moth-proofing compounds—their composition and patents. C. E. MULLIN. *Textile Colorist* 48, 89-91 (1926).—A discussion of the various patents upon this subject with particular reference to those covering *Eulan F. Extra* and *BL*, and *Larvex*. CHAS. E. MULLIN

Naphthophenothiazines (Brit. pat. 236,795) 10.

TROTMAN, S. R., AND TROTMAN, F. R.: **The Bleaching, Dyeing, and Chemical Technology of Textile Fibers.** London: C. Griffin & Co., Ltd. 610 pp. 30s.

Dyes. BRITISH DYESTUFFS CORPORATION, LTD., K. H. SAUNDERS and H. GOODWIN. Brit. 242,061, Oct. 22, 1924. 1-Amino-2-hydroxy-3-carboxynaphthalene-6-sulfonic acid is prepd. by sulfonating β -naphthoic acid, coupling the sulfonic acid obtained with a diazo compd. and reducing the azo compd. Monoazo dyes, giving fast pink to bluish red shades when chrome-printed on cotton, are made by coupling this sulfonic acid with 3'-carboxy-1-phenyl-3-methyl (or carboxy)-5-pyrazolone, 3'-hydroxaminophenyl-3-methyl-5-pyrazolone or similar compds. The 3'-hydroxaminophenyl-3-methyl-5-pyrazolone may be made by condensing the hydrazine obtained from the diazo compd. of *m*-HONHC₆H₄NH₂ with Et acetoacetate.

Dyes. W. P. BATES. U. S. 1,572,417, Feb. 9. Intermediates which give orange

to brown dyes are formed by adding a diazonium compd., e. g., diazotized aniline, to *m*-phenylenediamine or other aromatic amine in the presence of H_2O while maintaining the reaction mixt. hot.

Azo dyes containing zinc. F. STRAUB and H. SCHNEIDER. U. S. 1,572,573, Feb. 9. Dyes obtained by coupling the nitrated diazo compd. of 1-amino-2-hydroxynaphthalene-4-sulfonic acid with α - or β -naphthol and reducing the nitro group are further treated with substances yielding Zn such as $Zn(OH)_2$ and its compds. with alkalis and NH_3 . The resulting dyes form dark powders dissolving readily in H_2O with violet coloration which changes to bluish red on addn. of caustic alkalis. They dye wool violet to brownish black tints which become gray to black by after-chroming.

Dyeing. BADISCHE ANILIN & SODA FABRIK. Brit. 242,233, Oct. 30, 1924. In dyeing either animal or vegetable fibers or piece goods, propylated or butylated aromatic sulfonic acids or their salts, e. g., Na isopropyl (or butyl) naphthalene sulfonate, are added to the dye bath or used for preliminarily treating the material, to produce dyeings of good fastness to rubbing.

Dyeing animal fibers. S. W. WILKINSON. Brit. 242,027, June 25, 1925. Fibers and fabrics such as wool, fur, bristles, silk, leather and feathers are treated with NH_3 and ozonized air to improve their power of absorbing dyes so that in some instances mordants are unnecessary.

Dyeing furs or other animal fibers. H. STEIN, W. E. AUSTIN and I. LIEBOWITZ. U. S. 1,573, 200, Feb. 16. Previous to dyeing, the material is treated with a bleaching soln. of H_2O_2 in the presence of a fiber-protective agent comprising $FeSO_4$ and NH_4Cl .

Dyeing textile materials with sulfur dyes. B. K. THURS. Brit. 236,617, April 3, 1924. Mech. features of froth dyeing.

Dyeing apparatus. SMITH, DRUM & Co. Brit. 236,728, July 8, 1924.

Steaming and aging apparatus for use in dyeing fabrics or warps. MATHER & PLATT, LTD., and J. LEONTIEFF. Brit. 236,620, April 4, 1924.

Apparatus for dyeing or other fluid treatment of skeins of textile fibers. J. BRAND WOOD. U. S. 1,572,637, Feb. 9.

Dyehouse ventilation system for eliminating vapors and preventing condensation. C. J. HEUSER. U. S. 1,572,288, Feb. 9.

Apparatus for "dry-spinning" of artificial filaments from cellulose acetate solutions or similar substances. E. PRINCE. U. S. 1,572,955, Feb. 16.

Apparatus for making filaments of artificial silk. SIEMENS-SCHUCKERTWERKE GES. Brit. 241,948, Oct. 24, 1924.

Spinning viscose. J. C. HARTOGS. U. S. 1,573,062, Feb. 16. $Fe_2(SO_4)_3$ or other ferric salt is added to an acid spinning bath to prevent evolution of H_2S .

Transparent, wool-like and other finishes on cellulosic fabrics. KNOW MILL PRINTING CO., LTD. and R. J. HANNAY. Brit. 236,643, April 9, 1924. Natural or artificial cellulosic yarns, fibers or fabrics are treated with H_2SO_4 together with sulfonic acids of the benzene or naphthalene groups or their compds. substituted with OH. The treatment may be preceded or followed by mercerizing, calendering, embossing or other finishing processes.

Pressure kier for treating cloth or yarn. W. C. FOULDS. U. S. 1,573,310, Feb. 16.

Impregnating composition for bags. NORSK HYDRO-ELEKTRISK KVAELSTOF-AKTIESELSKAP. Norw. 42, 235, Dec. 21, 1925. A compn. especially suitable for impregnating bag fabric is produced by heating a mixt. of unsatd. oils, sulfur and asphaltic bitumen.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

True colloidal paints. SAMUEL CABOT. *Paint Oil Chem. Rev.* 81, No. 9, 10(1926) --- A brief review of the causes of chalking, peeling and spotting in paints. These characteristics are largely avoided by prepg. the pigments of colloidal size by means of "direct disruptive force" and a protective agent. These particles are negatively charged and show Brownian movement. There is practically no tendency for pigment and vehicle to sep. Tinting power and brilliance of color are increased. Priming qualities are improved as a result of the capillary action of surface pores on the fine particles.

ROBERT J. MOORE

Problems in paint and varnish technology. The need for experimental investigation. H. H. MORGAN. *J. Roy. Soc. Arts* 74, 271-86(1926). E. H.

Laboratory and test fence. W. T. PEARCE. *Paint, Oil Chem. Rev.* 81, No. 8, 10-11 (Feb., 1926).—This is a discussion of the relative merits of paint and varnish test in the lab. and on the test fence. P. outlines some of the questions needing investigation, and takes up the problems of exposure testing, such as the structure and moisture content of the wood painted, the direction and angle of exposure, and the method of inspecting the tests.

H. STORRTZ

Preservative coatings for structural materials. *Rept. of Comm. D-1, Am. Soc. Testing Materials* 44, 67 pp. (preprint) (June, 1925).—Exposure tests have been carried out on white paints to det. the relative dirt collection of paints of low and high pigment. White lead alone, and mixts. of ZnO with titanox, lithopone and white lead, resp., were reduced with various proportions of raw linseed oil, turpentine, liquid drier and heat-treated tung oil. After exposure for 3 months, the majority of expts. showed a compd. pigment consisting of ZnO 30%, and titanox 70%, to be the cleanest. The tests seem to indicate that the most rapid deterioration of paint occurs where it has been applied over a badly rusted surface; sand blasting or pickling of the steel seems preferable to hand cleaning. From the results of tests on 21 anticorrosive and anti-fouling paints coated on panels and submerged in the sea for 4 months, the following tentative specifications are given: Anti-fouling paints to contain in each U. S. gallon, both Cu and Hg in not less than the following amts.: for general service, for Northern temperate waters, for Southern temperate waters, and for tropical waters, Cu 14 oz., 25 oz., 20 oz., and 14 oz., Hg 7 oz., 1.5 oz., 5 oz., and 14 oz., resp., the Cu and Hg to be present as compds. sol. in distd. water at 20° to not more than 1 part in 15,000 by weight, and so finely divided that not more than 2% is retained on a No. 325 U. S. standard sieve. Fouling and corrosion appear as much dependent on variations in the vehicle as on the pigment. Proposals for the standardization of service tests of exterior varnishes, including a standard black undercoat, are minutely described. Full details are given of tentative methods for routine analysis of white linseed oil paints, and for testing shellac varnish; also specifications for dry bleached shellac, lithopone, lampblack, bone black, chrome yellow, pure chrome green, and reduced chrome green; requirements for sampling tung oil, and a definition of the term "screen" or "sieve."

B. C. A.

Toxic compositions to prevent fouling of steel ships and to preserve wood bottoms. H. A. GARDNER. *Paint Manufs. Assoc. of U. S., Circ. No. 259, 232-71* (1926).—A résumé of results of 4 yrs'. research on materials to prevent the fouling of metal by barnacles, hydroids, ascidians and bryozoa, and on materials to prevent the destruction of submerged wood by *Teredo* or *Limnoria*. On running ships from salt into fresh water death of the barnacles occurs, apparently as a result of osmosis, but the mantels remain attached. Smoothing or polishing the surface does not prevent fouling. Expts. on various colors showed that the comparative freedom from fouling on white and light tints is probably due to zinc oxide. Hundreds of anti-corrosive and anti-fouling compns. were tested, including animal and vegetable oils, metallic soaps, rubber, finely divided metal powders, org. Hg compds., org. acids, resins and alkaloids. A combination of coal tar, rosin and certain soaps proved to be valuable in preventing barnacle attachment. Copper soaps are particularly efficient. Of hundreds of hot-application paints investigated, only a few proved valuable. Ester gum incorporated in the paint makes the film too insol. The best results are obtained when the film is of a sol. or soft nature. Pine oil incorporated in the thinners gave much better results than mineral spirits, turpentine and other high-boiling ingredients. Phenol-formaldehyde resins dissolved in alc. or C_6H_6 gave very good results. Nitrocellulose coatings failed quickly. Tung-oil fatty acids gave excellent results. The claim that special steel plate, such as is used in the passenger ship "Leviathan," would not foul if left unpainted did not prove true. Zn and Cd coatings sprayed over metal and wood, while non-corroding, fouled rapidly. A formula which gave excellent results as a copper paint for wood bottoms, as well as being efficient as a general anti-fouling paint, is: rosin 164 lbs., coal tar 49.5 lbs., coal-tar naphtha 451 lbs., beeswax $3\frac{3}{4}$ lbs., Mn linoleate 145 lbs., Venetian red, dry, 105 lbs., ZnO, dry, 210 lbs. There are included 68 formulas representative of hundreds exposed, and photographs of tests.

ROBERT J. MOORE

Notes from the practice. II. A white lead substitute. J. PRESCHER AND R. CLAUS. *Z. Nahr. Genussm.* 50, 430 (1925).—The pigment freed from oil consisted of lithopone (35.3% ZnS and 64.7% $BaSO_4$).

WILLIAM J. HUSA

α - and β -Eleostearin. Liquid and solid granular light-induced products from tung oil. H. A. GARDNER AND H. C. PARKS. *Paint Manufs. Assoc. of U. S., Circ. No. 256, 207-15* (1925).— β -Eleostearin formed in light-struck tung oil does not render the oil unsuitable for varnish making. The crystals sepd. from the oil by washing with cold Me_2CO gave a shorter heat test than the original oil. Dissolved in C_6H_6 and poured on

glass, the crystals dried slightly faster than the liquid residue so dissolved and poured.

ROBERT J. MOORE

Machinery for hulling and crushing tung seed. With notes on constants of abnormal oils. H. A. GARDNER. Paint Manufrs. Assoc. of U. S., *Circ.* No. 255, 199-206 (1925).—Detailed analyses are tabulated of oils made by different methods of hot and cold pressing seeds imported from China, compared with commercial Chinese tung oil and Florida-grown tung oil.

ROBERT J. MOORE

Perilla and chia culture experiments of 1925. With results on chia crushing experiments. H. A. GARDNER. Paint Manufrs. Assoc. of U. S., *Circ.* No. 257, 216-27 (1926).—Economics of production, planting time and methods, weather conditions, and results are given for the growing of perilla seed in Georgia and Florida. Florida plantings were unsuccessful because of unprecedented drought. Perilla seed culture probably will not be taken up rapidly in America because of relatively low yields and difficulty in harvesting. Data are given on crushing and hot and cold pressing of chia seed obtained from Mexico. Consts. for hot-pressed and cold-pressed, resp., are: $d_{15.5}$ 0.9333, 0.9332; n_D 1.4796, 1.4796; I value 190.6, 191.4; sapon. value 195, 196; nonsapon. matter 1.16, 0.87; acid value 3.32, 1.80.

ROBERT J. MOORE

Notes on alfalfa seed oil, hempseed oil and safflower seed oil. H. A. GARDNER. Paint Manufrs. Assoc. of U. S., *Circ.* No. 258, 228-31 (1926).—Attention is called to the possible use of these oils in white paints to reduce the yellowing shown by linseed oil. Alfalfa seed yielded only 11.2% oily substances. The oil had an I value of 165 and an acid value of 2.5. Safflower seed oil may be refined to a very light color. Compared with linseed oil in paints, it shows very little yellowing. Hempseed oil, I value 155-160, is almost equal to linseed in drying. It yellows less than linseed.

Chemistry and manufacture of writing and printing inks. WM B. GAMBLE. *Introduction*, by H. M. LYDENBERG. N. Y. Public Library, *Separate* 1926, 105 pp.—A list of references in the N. Y. Public Library.

E. J. C

Airplane dopes. MAURICE DESCHIENS. *Chimie et industrie* 15, 18-27 (1926)—Review. A. PAPINEAU-COUTURE

The seeds of *Mercurialis* species (GILLOR) 11D. Oil sampler for tank-car shipment (GNAEDINGER) 27. Cellulose ester lacquers (U. S. pat. 1,572,461) 23.

Preparing cement surfaces for painting. A. HARRIS. Brit. 241,976, July 24, 1924. A mixt. formed from HOAc, H₂SO₄, turpentine and H₂O is applied to cement work before painting it.

Coloring waxes, rubber, shellac, etc. BADISCHE ANILIN- & SODA-FABRIK. Brit. 242,274, Nov. 3, 1924. Coloring substances which are practically insol. in the usual solvents are "nearly colloiddally dispersed" in the plastic materials. Shellac colored with lithol-fast scarlet R in borax soln. may be used as an ink.

Protecting metal surfaces from acids, etc. A. C. HOLZAPFEL. Brit. 241,970, July 1, 1924. Cleaned metal surfaces are coated with a mixt. comprising rubber, resin and ground asbestos or other acid-resisting pigment, and then provided with an overlying coating of a cellulose ester varnish or paint.

Tung oil. TAUBMANS, LTD. Brit. 236,928, July 10, 1924. Tung oil for use in paint or varnish, etc., is treated to delay polymerization and prevent gelatinization when heated, by heating the oil with one of the B-contg. acids to a temp. of about 260° and allowing it to cool until the desired viscosity is reached.

Mat varnish effects on glass. R. K. HEARN. Brit. 236,709, May 30, 1924. Naphtha or other "suitable adulterant" is added to varnish for attaching silk sheets to glass; or the silk may be backed with crinkled Sn foil.

Composition for removing baked enamel. G. W. BLAIR. U. S. 1,572,839, Feb. 9. Shellac is mixed with smaller quantities of lacquer and paraffin and with a still smaller proportion of NH₄OH.

"Turpentine substitute." C. C. MONGER. U. S. 1,572,902, Feb. 16. An acidulated mixt. of resin and naphtha is distd. after a preliminary heating below the temp. of distn.

Furniture polish. J. JOHANSEN. U. S. 1,572,021, Feb. 9. Linseed oil 6 oz., kerosene 4 oz., vinegar 4 oz., turpentine 2 oz. and spirits of camphor 1 dram.

Printing inks. SHUCK, MACLEAN & CO., LTD., and W. P. PRICE. Brit. 236,611, March 13, 1924. Printing ink is mixed with an emulsion of the oil-in-H₂O type compris

ing a deliquescent salt such as CaCl_2 and which may also contain NH_4Cl or borax and petroleum jelly. The emulsion is preferably mixed with lithographic varnish and then incorporated in the ink; its use avoids the need of damping-app. in lithographic or printing processes.

Resinous coating composition containing chlorinated rubber. N. BOEHMER. U. S. 1,572,065, Feb. 9. A compn. suitable for coating concrete, etc., comprises chlorinated rubber and at least an equal quantity of cumarone resin, together with a solvent such as C_6H_6 or solvent naphtha.

Distilling natural resinous substances. J. M. A. CHEVALIER, P. BOURCET and H. REGNAULT. U. S. 1,572,766, Feb. 9. A natural resinous material such as gum of the pine, Canada balsam or Peruvian balsam is mixed with 1-5% of H_3PO_4 and the mixt. is distd. at a temp. which is progressively raised until the temp. of the vapors reaches about 310° , in order to obtain rapid distn. of a *turpentine substitute* in good yield.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The chemistry of oils and fats. I. The synthesis of the higher unsaturated acids. R. ROBINSON AND G. M. ROBINSON. *Food Investigation Board, Report for the year 1924 Dept. Sci. Ind. Research* 1925, 62-3 —The Na deriv. of a monoalkylated acetoacetic ester was condensed with the ester chloride derived from a dibasic acid and the product was hydrolyzed. The acetoacetic ester contributes only a methylene group to the final product. Thus any ketone of the form $\text{R}.\text{CH}_2.\text{CO}.\text{R}$ can be synthesized.

I. W. RIGGS

Oil sampler for tank-car shipment. R. J. GNAEDINGER. *Paint Manufacturers Assoc. of U. S., Circ. No. 254*, 195-8(1925).—The sampler tube is divided into small cells of varying cross-sectional areas, so that the amt. of oil taken from different layers in the tank is proportional to the total vol. of that layer.

ROBERT J. MOORE

Notes from the practice. I. Testing of cacao fat for alkalies and alkaline earths. J. PRESCHER AND R. CLAUS. *Z. Nahr. Genussm.* 50, 429-30(1925)

W. J. H.

Detection and determination of coconut oil and milk fat in cacao fat. J. KUHLMANN AND J. GROSSFELD. *Z. angew. Chem.* 39, 24-6(1926). —In the analysis of mixed fats it has been found advantageous to det. *A* the fatty acids whose Mg salts are sol. in water but whose Ag salts are insol. and *B* the volatile fatty acids with sol. Ag salts. Both values are expressed in cc. of 0.1 *N* soln. The *A* no. for coconut oil is about 27.7 but for butter fat it is 6.7. The *B* no. for the former is 2.75 and for the latter 33.4. The *A* no. for pure cacao butter is about 0.1. Detailed directions for detg. these 2 values are given and it is shown how to interpret the results

W. T. H.

Oil-producing palms. PÉLICIEN MICHOTTE. *Matières grasses* 15, 6354-8, 6415-8, 6509-10, 6528-30, 6547-50 (1923); 16, 6709-12(1924); 17, 7034 5, 7062-3, 7308-11, 7335-7, 7363-5(1925); 18, 7419-21(1926).—A monograph. The production, compn. and uses of the various products of the different kinds of palms are covered

A. PAPINEAU-COUTURE

Safflower seed oil. FRANK RABAK. *Paint, Oil Chem. Rev.* 81, No. 7, 10-2 (Feb. 1926).—The oil from the safflower seed (*Carthamus tinctorius* L.) promises to be of value in the industries using drying oils. The seed somewhat resembles sunflower seed and yields 20 to 30% oil, which shows the following properties: for a Virginia oil: sp. gr. at 15.5° —0.9263; refraction at 24° —1.473; acid no.—12.7; sapon. no.—204.9; I no. (Hanus)—143.5; loss on heating at $108-110^\circ$ —0.18%; unsaponifiable matter—1.02%. A South Dakota oil showed an acid no. of only 1.1, this oil coming from a better crop of seed. Safflower oil absorbs its max. content of O in 7 days, but the film is more tacky than that from linseed oil. The flash point was found to be 266° by the "open test" at method. Oil bodied by heating for 2 hrs. at 305° to 315.5° tested as follows: sp. gr. at 15.5° —0.9632; acid no.—5.28; sapon. no.—199.7; and Hanus no.—90.6. Co resinate and linoleate are the most satisfactory driers, giving a dry non-tacky film in 22-28 hrs., as against 46-94 hrs. with Pb and Mn driers. Exposure tests with white lead as pigment showed good results.

H. STOERTZ

Grape seed oil. P. VIALA. *Rev. vit.* 64, 121-3(1926).—Grape seed oil closely resembles castor oil in its phys. properties, and it should find its chief value as a substitute for the latter, in lubrication. Proper precautions in handling the raw material prevent the development of an acidity of over 2%.

P. R. DAWSON

Disturbances in the production of lye-glycerol. ANON. *Seifensieder-Ztg.* 53,

41(1926).—A sudden darkening of lye-glycerol during concn. was traced to the presence of 1.0–1.5% NaClO_3 , probably a constituent of electrolytic NaOH used in sapon.

P. ESCHER

Analyses of soap solutions of phenols. F. DI STEFANO. *Ann. chim. applicata* 15, 573–80(1925).—Though numerous methods have been proposed for analyzing soap solns. of phenols (Creolin, Seifenöl, etc.), they are almost without exception (cf. Bohrisch, *C. A.* 16, 790) limited to detg. the amts. of phenols, soap and free alkali. Since the oil or fat from which the soap is prepd. influences the phys. properties of the final soln., a method was developed for identifying the oil or fat used. Dissolve 20 g. of soln. in 60 cc. of H_2O , acidify with H_2SO_4 , steam-distil to remove the phenols, cool, sep. the fatty acids from the supernatant H_2O , dissolve them in aq. NaOH , filter, add excess dil. H_2SO_4 , filter, wash free of H_2SO_4 with hot water, dissolve the acids in Et_2O , distil off the Et_2O , dry at 100° , and det. the m. p., I no. and acetyl no. Application of this method to com. soap-cresol solns., supposedly prepd. from castor oil, which contained the required amt. of cresol and soap, but which were not sol. enough in H_2O , showed fatty acids corresponding to olein and not castor oil. The results obtained with the method emphasize the influence of the nature of the soap on the soly. of the cresol and, therefore, on the properties of the final product.

C. C. DAVIS

Durable shaving soaps. C. BAIER. *Am. Perfumer* 20, 731–2(1926).—A discussion and comparison of an American vs. a German shaving soap. The American soap is preferred to the German because its compn. is more advantageous; it consists of 90% stearin, 10% coconut oil and large amt. of potash, while the German soap was made from 75% tallow, 10% lard, 15% coconut oil and less potash. The former has less unsatd. glycerides and will, therefore, be the more durable.

E. SCHERUBEL

The Burnus of after-war-time and the Wermil (Zegil). P. HEERMANN. *Seifensieder-Ztg.* 53, 59–60, 80(1926).—H. reports on the effectiveness of Burnus and Wermil as cleansing agents. Burnus is a prepn. contg. the tryptic enzyme of the pancreas and its effectiveness is due to the digestion of albuminous matter during the pre-soaking period of dirty wash; the fiber is not attacked. Wermil or Zegil is a new cleansing mixt. contg. 12.5% fatty acids, 0.07% active O_2 and 49% Na_2CO_3 ; ferments and enzymes are absent. The tests were made by preliminary soaking of soiled test pieces, each lot separately, followed by a washing of all lots in the same soapsuds; the conditions of concn., temp., etc., were so selected as to obtain a cleansing effect just short of satisfactory for the best agent and thus show the greatest difference between good and bad compds. Burnus is a good cleansing aid; Wermil is not. Its small soap content is lost in hard H_2O .

P. ESCHER

Calculation of rosin in a kettle-charge. C. BERGELL AND C. WILMS. *Seifensieder-Ztg.* 52, 1003–4(1925).—Lab. expts. showed that 97% of water-white rosin went into soap and 3% into the lye, while only 92% of the J grade of rosin went into soap and 8% into the lye.

P. ESCHER

The seeds of *Mercurialis* species (GILLOT) 11D. Coloring waxes (Brit. pat. 242,271) 26.

STEINER, O.: *Industrie der Fette und Seifen*. Dresden and Leipzig, 1925: Theodor Steinkopff. viii + 83 pp. Reviewed in *Rev. chim. ind.* 35, 25(1926).

Albuminous and fatty products by autolysis of animal and vegetable substances. M. KAHN. U. S. 1,572,933, Feb. 16. About 0.1% each of toluene and CHCl_3 are added to substances such as fish which are subjected to autolysis.

Treating nut kernels to prevent rancidity. M. A. JULIEN AND D. G. GOONERWAR DENE. Brit. 236,713, June 11, 1924. A protecting layer is formed on the surface of coconut kernels or other oil-bearing kernels by the use of coagulants such as alum. formaldehyde or $\text{K}_2\text{Cr}_2\text{O}_7$; oxidizing agent such as Cl , HNO_3 or Na or K permanganates, or mild disinfectants such as borax or H_3BO_3 .

Detergent. W. SCHNEIDERMAN. U. S. 1,572,814, Feb. 9. A compn. for cleaning grease from the hands, etc., comprises soap cream and turpentine in about equal quantities, a larger quantity of petrolatum and a small proportion of CCl_4 .

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

The sugar industry in Cuba. ANON. *Intern. Sugar J.* 27, 593-9(1925).—An economic survey. W. L. OWEN

The influence of lime upon the velocity of crystallization of sucrose. I. A. KUCHARENKO AND B. G. SAVINOFF. *Sucr. Belge* 45, 205-8(1925).—The presence of CaO in a sucrose soln. has a retarding effect upon the velocity of crystn. The retarding effect brought forth by CaO upon the velocity of crystn. in a sugar soln. is increased with the increase of the amt. of CaO in the mother liquor. T. MARKOVITS

Spray system of juice screening. H. F. HADFIELD. *Facts about Sugar* 21, 210 1 (1925).—A juice screen for purifying sugar juices is described. Illustrated. T. MARKOVITS

Thick-juice densities at the pressure evaporator station and juice concentrators. K. SÁZAVSKÝ. *Z. Zuckerind. czechoslov. Rep.* 50, 60-4(1925); *Listy Cucrov.* 43, 87ff. (1925).—If the density of thin juice varies, a pressure evaporator does not give corresponding variations in thick juice concn., because with denser thin juice less steam is used for heating; hence less evapn. must be done in the pressure evaporator. Increased d. of thick juice can only be obtained by using a concentrating evaporator in connection with the pans, or blowing off steam from the pressure evaporator. S. carries out several calcs. showing that this concentrating evaporator does not affect the heat balance of the mill or the operation of the pressure evaporators. It is to be considered a part of the pan station, not the evaporator station. W. L. BADGER

The theory of evaporation with especial reference to sugar factory operation. BOHUMÍR PRÁČEK. *Z. Zuckerind. czechoslov. Rep.* 50, 161-7, 169-73(1926); *Listy Cucrov.* 43, 373 (1924-5); cf. *C. A.* 18, 3122; 19, 3610.—Mathematical W. L. BADGER

Evaporator bodies with or without juice circulation. K. SÁZAVSKÝ. *Z. Zuckerind. czechoslov. Rep.* 50, 71-2(1925).—A discussion of special juice circulating devices such as used in the Vincik-Turek evaporator. It is shown mathematically that such constructions increase the capacity of an evaporator as compared to the usual construction in which the whole body is filled with juice of the final density. W. L. B.

The influence of filter material on the quality of the work of the filter station. JAROSLAV HRUDA. *Z. Zuckerind. czechoslov. Rep.* 50, 75-80, 81-7, 89-93, 113-8, 121-8 (1925).—Elaborate tests of 4 kinds of filter cloth. Exptl. data are given in full. The cloths are described only by trade names, so that the conclusions are not of general significance. W. L. BADGER

Vallez filters in France. ANON. *J. fabr. suc.* 67, 1(Feb. 6, 1926).—A description is given of the Vallez filters in a sugar factory in France. Detailed observations are included on the time required for various operations. The working of the filters is considered satisfactory, and it is concluded that their cost is amortized in 2 or 3 years by economies in labor and filter cloths. T. MARKOVITS

Experiments on the clarification of cane juice using the "streamline" filter. C. F. ARMSTRONG. *Intern. Sugar J.* 27, 424-6(1925).—Expts. carried out in Guatemala on the filtration of cane juices with the "stream line" filter showed that the best results are obtained when the filter packs are cleaned with compressed air just as they are emerging from the juice. Increasing the distance between the leaves increased the rate of filtration. A max. of 15 gals. of juice per sq. ft. per hr. was obtained. The filtration can best be applied in cane sugar factories, to the juice in the early stages of clarification, after defecation. The filtering area required for a plant grinding 1000 tons of cane daily will be 1092 sq. ft. This is small in comparison with a carbonation factory in which the filtering area required was 5184 sq. ft. for a grinding capacity of only 450 tons per day, or a sulfitation sugar factory in Argentina where 40 presses with a combined filtering area of 18,000 sq. ft. were required for a 1300 tons milling capacity, all the juice being filtered. W. L. OWEN

Deterioration of cane mill juices from the aspect of acidity increase. W. L. McCLEERY. *Intern. Sugar J.* 27, 543-6(1925).—It is becoming more and more evident that there is considerable loss of sucrose in juice during milling as the result of bacterial activities. The difficulty has been to det. these losses, because of the inadequacy of present methods of detg. accurately the sucrose entering the factory. That such losses in sucrose do occur is very strikingly indicated in the purity differences between first expressed juice and mixed juice in factories operating under the usual conditions and the lessened difference in the purities when steps are taken to keep the plants in sanitary condition. Another evidence of the deterioration of cane juice during milling is the

increased acidity of the mixed juice over the freshly extd. juice. The increase in acidity from the first to the last mill is especially marked during the latter part of the week, indicating that it resulted from an increasing accumulation of infection around the mills. By keeping a careful record on the increase in acidity, and including these data in the control sheets of the lab. it is possible to keep acidity at a min. at all times. The test is by titration against $N/2.8$ NaOH and sensitive neutral litmus paper. Each cc. of the alkali represents 0.01% acidity in terms of minus CaO. The acidity is expressed as parts per 100 Brix. If it can be assumed that the acidity increase is due to AcOH formed at the expense of sucrose, the difference in the 1923 and 1924 acidities would represent a saving of 1.75% for the latter year. Correlative data to show that this is correct are lacking.

The chief losses in the manufacture of sugar from Java cane. W. L. OWEN. *Rev. ind. agr. Tucuman* 16, 46-50 (1925).—Owing to sucrose inversion [the commonly cultivated Java cane varieties P. O. J. 36 and 213 suffer considerable and rapidly increasing losses when stored before milling. The loss is actually much greater than the decrease in sucrose content because of difficulties in defecation, filtration and crystal Damping and protection from air may partly inhibit deterioration. P. O. J. 2725, P. O. J. 228, D. 1135 and the purple, or striped creole cane do not markedly deteriorate after being cut. P. O. J. 2725 is most suitable for the majority of soils. M. J.

Chemical control in cane sugar factories. H. A. COOK. *Facts about Sugar* 20, 1234-6; *Intern. Sugar J.* 27, 602 7 (1925).—C. emphasizes the necessity of a complete equipment for chem. control and points to the fact that in Hawaii a large amt. of investigational work on clarification problems has been conducted. Work on liming of juices for the best results in clarification gave positive evidence that there is a point in reaction at which the best results are secured. The P_2O_5 content of the juices is a vital factor in clarification. The max. increase in purity for this method of clarification was obtained at approx. the same reaction, *viz.*, neutral or slightly alk. to phenolphthalein, as that at which the optimum clarification was secured. At the time of these investigations an instrument or other material for the detns. of p_H values was not available. It has since been demonstrated that a definite relation existed between this reaction and the H ion concn. to which the juice is limed. Available potentiometric methods are not adaptable to use in plantation labs. This is due not only to the cost of such equipment and to the skill and care required for their use but also to the inherent characteristics of the H electrode when used in org. solns. There remained the choice of some colorimetric method or the adaptation thereof. The method of Clark and Lubs using comparator tubes with buffer solns. or the spot test method did not seem to possess suitable characteristics for general use, mainly because these buffer solns. could not be counted upon to retain their values for any length of time. The alternative remained to produce color charts of standard color values. The prepn. of these charts was undertaken and the indicators proposed by Clark and Lubs were found most suitable. Inasmuch as buffer solns. are eliminated and the color charts are made the basis of the values, a certain personal element enters into the detn. Even in view of such limitations as may be inherent in the method, however, it is a big step in the right direction, and results can be secured that are very close to those secured by the use of the potentiometer. T M

Fuel economy in the cane sugar factory. G. H. W. BARNHART. *Intern. Sugar J.* 27, 428-33 (1925).—The general rule for power requirements of mill engines is 15 indicated h. p. per ton of fiber ground per hr. for a 2-roll crusher, 30 per ton of fiber in a 3-roll crusher, and 30 additional for each 3-roller mill in the train. The ideal arrangement for a mill power plant where much outside power is supplied is a non-condensing turbo-generator, running in parallel with a condensing unit, the power to be controlled by a back pressure regulator which controls the load. Standard practice indicates a boiling heating surface of 450 sq. ft. of fire tube boilers for each ton of cane ground, per hr., which corresponds to 375 sq. ft. in water tube boilers. If the percentage of CO_2 in the flue gases is 12-14, and flue gas temp. does not exceed $600^\circ F.$, then the bagasse may be said to be burned efficiently. In practice there is a tendency to use too much air on the furnaces in an effort to keep the CO within the prescribed limits with a resulting loss of efficiency as evidenced by excessive flue gas temp. Measurement of piping in sugar factories has shown that for each ton of cane ground per hr. there are 287 sq. ft. of radiating surfaces of pipes in the factory. Evapn. from bare pipe would be equal to 12.64% of total bagasse, which loss could be reduced to 1.61% with a 1" layer of MgO insulation, and to 1.46% with a 1.5" layer. Four factors have contributed to the gradual increase in heating surface required in pans, evaporators, and heaters in cane sugar factories. These are an increase in the grinding rate, an increase in power requirement due to the introduction of the Messchaert groove, a decrease in operating pressure due to lap seam

boilers, the introduction of the calandria type of vacuum pan permitting faster boiling.

Soil hygiene in relation to cane "diseases." MAURICE BIRD. *Intern. Sugar J.* 27, 423-4, 536-7 (1925).—Extended study of the pathological condition of sugar cane, as induced by soil conditions, has shown that it is due to a high MgO-CaO ratio. The phenomenon usually follows a period of very rapid growth on the part of the cane. The first evidence of it is a withering at the tip, the cessation of growth, and finally the plant dies. Analyses of the soil in which this pathological condition manifests itself shows it to be normal in every respect, except perhaps for its low P_2O_5 content. Analyses of the ash of the cane and the soil adhering to its roots show that the MgO-CaO ratio is much higher in the diseased cane than in the sound cane, and the same applies to the dirt from the roots of the canes for the 2 sources. Analyses of the roots, stalks and leaves of the sound and diseased canes show also that the MgO-CaO ratio is much higher in the latter than in the former, and the same relationship exists as regards the soils on which the 2 types are produced. This pathological condition is more pronounced upon stiff clay soils, which are lacking in vegetation, and are more impervious to the penetration of H_2O . Conclusion: The chief factor in promoting this condition in the cane is a deficit in lime, caused by the sluggish circulation of soil moisture and the lack of sol. lime at the roots of the plant, and a consequent excessively high MgO-CaO ratio.

W. L. OWEN

A method of handling cane tassels for breeding work. J. A. VERRET, Y. KUT-SUNAI, U. K. DAS, RAYMOND CONANT AND TWIGG SMITH. *Intern. Sugar J.* 27, 412-8 (1925).—In handling cane tassels for breeding purposes, it is difficult to prevent the cut tassels from wilting and dying. It was found, after a very extensive investigation, that a 5% soln. of SO_2 gas, when used in the proportion of 1 100, would preserve the tassels in a state of perfect freshness for a period of 2 weeks. The substances tested included $HgCl_2$, NH_4Cl , $PbCl_2$, $MgCl_2$, $CHCl_3$ and C_2H_5OH . The $HgCl_2$ prevented the formation of the slime, which was thought to be the cause of the deterioration of the tassels but the plants seemed to be injured by it. The SO_2 soln. has to be very carefully prepd. so as to avoid the occurrence of any free H_2SO_4 . It is necessary to place the tassels in the soln. immediately after they are cut. When tassels are to be conveyed for any distance the cut ends are immediately submerged in water and kept there until they are brought to headquarters, when the lower joint of the stem is removed while still submerged, and the tassels are then transferred to the SO_2 soln.

W. L. OWEN

Milling of Uba cane in Natal. R. F. HUTCHESON. *Intern. Sugar J.* 27, 632-7 (1925).—For the efficient milling of Uba cane the following conditions should be maintained: (1) Good feeding at the cane carrier. (2) The cane carrier to be driven by an independent engine or motor with a variable speed. (3) Levelling knives. (4) A double crusher. (5) All rolls provided with large intermeshing grooves. (6) Rolls run as slowly as possible. (7) Trash plates kept low. (8) Heavy maceration.

W. L. O.

The "crusher shredder." ANON. *Intern. Sugar J.* 27, 418 23 (1925).—The cane first passes between a pair of rollers, having very coarse teeth and moving under very heavy pressure. While the crushed cane is still held in the rollers, it comes in contact with a 3rd or shredding roller, which combs the bagasse into shreds. The shredded cane is then thrown forward into an inclosed casing toward the mills, the extd. juice being kept free from the fiber, and reabsorption is thus reduced to a min. The shredder roller is independently driven, and its speed can thus be regulated as desired. In Java practice it has been found that a speed of 400 r. p. m. is ample to obtain the greatest efficiency. The advantages of the "Crusher Shredder" are: (1) the yield of juice is increased; (2) there is no powdered bagasse with which to contend; (3) the power consumption required for shredding is much less than that required with the ordinary type of shredder; (4) there is less expense required in the replacement of parts as there is less wear on the bearings.

W. L. OWEN

Molasses analysis. H. CHARLIER. *Sucre Belge* 45, 208-10 (1925).—C. emphasizes the necessity of a uniform method of detg. the total sugars in molasses and points out the difficulties which exist in detg. the density with the spindle on account of the different Baumé scales.

T. MARKOVITS

Changes in the composition of frozen beets. JIRÍ VONDRÁK. *Z. Zuckerind. cechoslov. Rep.* 50, 130-2 (1925); *Listy Cucrov.* 43, 555ff (1924-5).—The invert sugar content of samples cut from the same beet and (a) frozen at once, (b) frozen, thawed, and frozen again, and (c) heated to 60° for 15 min., and then frozen, were: immediately after freezing, (a) 0.19, (b) 1.15, (c) 1.00%; after 34 days, (a) 0.47, (b) 4.5, (c) 7.8%; after 67 days, (a) 0.81, (b) 6.0, (c) 8.4%. This increase is to be ascribed to the action of invertase normally present in beets.

W. L. BADGER

Active carbons. CHR. MRASEK. *Z. Zuckerind. cecoslov. Rep.* 50, 142-4(1925).—Polemic. W. L. BADGER

The importance and economy of active carbons for filtering thick-juice. P. HONIG. *Z. Zuckerind. cecoslov. Rep.* 50, 118-20(1925).—Reply to Sazavsky (*C. A.* 19, 3610). A few expts. are cited showing the comparisons between carboraffin and norit on the same juices. Percent color removed and viscosity after filtration are about the same for both; alkyl. of filtered juice is less with carboraffin. Nevertheless H. concludes that norit is superior. W. L. BADGER

Efficiency of decolorizing carbons. L. WICKENDEN. *Facts about Sugar* 21, 230-1(1925).—A comment upon the paper of Blowski and Bon (*C. A.* 20, 836). T. M.

Boneblack, carboraffin, norit. FRANZ NOSEK. *Z. Zuckerind. cecoslov. Rep.* 50, 93-6(1925).—Polemic. W. L. BADGER

May Chile saltpeter be replaced by other nitrogenous fertilizers [for beets]? (BINDERBECK) 15.

Sucrose from molasses. H. S. PAINE, C. F. WALTON, JR., and V. BIRCKNER. U. S. 1,572,359, Feb. 9. Invert sugar in cane molasses is removed by a selective fermentation which may be effected by the use of organisms of the "*S. apiculatus* group". Residual sucrose is then pptd. as saccharate by the addn. of lime and the sucrose recovered by decomposing the saccharate, filtering the sucrose soln. and crystg.

29—LEATHER AND GLUE

ALLEN ROGERS

The behavior of sharpened limes in unhairing. I. A microscopical investigation of the unhairing action of caustic alkalis and sodium sulfide. MADGE KAYE AND R. H. MARRIOTT. *J. Intern. Soc. Leather Trades Chem.* 9, 591-8(1925).—The action on pelts of lime, Na_2S , NaOH , NaHS and various mixts. of them was followed under the microscope by continuous observation and by examn. of sections cut at different time intervals. In all cases "the cellular tissue of the hair roots and follicles and the base of the epidermis" is the first structure attacked. II. The unhairing action of sulfide and polysulfides. *Ibid* 599-611. III. The action of caustic alkalis, sulfides, and polysulfides on the hair shaft. *Ibid* 612-9.—M. distinguishes between the action of the reagents named on the hair root (unhairing action) and on the hair shaft. Both sulfides and hydroxides must be present to obtain satisfactory unhairing. This is attributed to the formation of the S ion by the action of the OH ion on the SH ion. The depilatory action of the polysulfides is less than that of sulfides, and is probably due to the S ion. When hair is treated with sulfide, the S ion decreases in the soln., while the total S increases to an approx. equal extent. Previous treatment of the hair with alkali prevents it from reacting with the S ion. It is suggested that the S ion combines with the hair by addn. to the cystine portion of the keratin mol., forming a sol. complex. The action of alkalis is to split off cystine, leaving a residue which cannot react with the S ion.

H. B. MERRILL

The tannin content of the oak. P. PAVLOVICH. *Collegium* 1925, 627-9.—The tannin content of the winter oak, *Quercus sessiliflora*, increases with age of the tree and also is much higher at the top and slightly higher at the root than at breast height.

I. D. C.

Histological leather investigation. LUDWIG JABLONSKI. *Collegium* 1925, 620-3.—Leather fibers can be stained and examd. after extg. with H_2O , with EtOH and then either with 5-7% $\text{Na}_2\text{S}_2\text{O}_4$ or 10-15% alc. H_2O_2 . Fibers were not damaged in 3 weeks by limes sharpened with Na_2S .

I. D. C.

The utilization of marine animals to supply tannery needs. TH. KÖRNER. *Leder-techn. Rundschau* 18, 1-7(1926).—The production and characteristics of oil, leather, etc., from marine animals are described.

I. D. C.

Electroosmotic tanning procedure. SARROT DU BELLAY. *Cuir tech.* 15, 75-8(1926).—A description and discussion of advantages claimed for this method of tanning.

H. B. MERRILL

Investigation of synthetic tanning materials. EDWARD WOLSENSKY. Bur. of Standards, *Tech. Paper* No. 302, 45 pp.(1925).—Soft, pliable and strong leather can be produced by tanning with condensation products of the sulfonic acids of monohydroxy-phenols with CH_2O , but the leather yield is low. Greater yields can be obtained with

sulfonated phenolformaldehyde resins and still greater yields of leather with a sulfonated phenol-acetaldehyde resin. Condensation products of resorcinol or pyrogallol with CH_2O or with $\text{C}_6\text{H}_4\text{O}$ were found to possess greater filling properties than any of the sulfonated products.

The reversal of double refraction of collagen fibers by some vegetable tannins. J. A. WILSON. A. KÜNZEL. *Collegium* 1925, 623-7.—By tanning with sumac, tea, divi-divi, algarobilla, or myrobalans the double refraction of collagen is changed from + to —. Other tannins lessen the + refraction. Syntans, sulfite cellulose, mineral tannins, HCHO or EtOH have no effect. This test may be used to det. the nature of the tanning material in leather.

Mechanical leather testing. LUDWIG JABLONSKI. *Collegium* 1925, 616-20.—Other tests are often more important than the detn. of tensile strength. Simple methods are given for testing H_2O absorption, elasticity and permeability to H_2O and air.

Note on the modified shake method (for tannin analysis). G. BALDRACCO. *Cuir tech.* 15, 99-101(1926); cf. C. A. 19, 3170.—Slight modifications in manipulation are suggested.

Modifications in the (European) official method for quantitative analysis of tanning materials (approved by the Paris conference, Sept. 1925). *Cuir tech.* 18, 97-8(1926).—Text of changes in details of procedure.

Effect of splitting on the tensile strength of leather. J. A. WILSON AND E. J. KERN. *Ind. Eng. Chem.* 18, 312-3(1926).—Charts showing how the strength and stretch of chrome- and vegetable-tanned calf leathers vary with the degree of splitting of the leather.

New leather preservatives in France. H. SCHMIDT. *Ledertech. Rundschau* 18, 18 9(1926).

CHAMBARD, P.: Contribution à l'étude du tannage au chrome. Paris: Dunod. 128 pp. Fr. 15.

Ornamenting leather with colored designs. W. KNOLL. U. S. 1,573,251, Feb. 16. Leather is coated with a background, a pattern is placed on this and the pattern design is applied in a decorative color and a fixing substance such as varnish. U. S. 1,573,252 specifies a similar process including the feature of shading off the design around the pattern.

Pyrroles and pyrocoll. J. MICHELMAN. U. S. 1,572,552, Feb. 9. Collagenous animal waste is subjected to destructive distn. out of contact with air, the distillate is condensed and the oily fraction is treated with a diluent such as toluene and filtered to obtain pyrocoll crystals which sep. The filtrate is fractionally distd. to obtain pyrrole, etc.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The chemistry of rubber and of gutta-percha. H. STAUDINGER. *Kautschuk*, Aug.-Sept. 1926; *Gummi-Ztg.* 40, 1095.—A review and discussion of previous work (C. A. 17, 2974; 18, 3490; 19, 1791). The term *eucolloid* is suggested for colloids such as rubber, in which the mols. constitute the individual colloidal particles (cf. C. A. 18, 3490). Since very long C chains are unstable, it is probable that these rubber macromols. split or dissociate, as a result of which rubber exhibits abnormal viscosity phenomena. In concd. solns. where the largest mols. are present, the viscosity is high, whereas there comes a point in the diln. where the viscosity suddenly decreases greatly because of the formation of smaller mols. Not only can *cyclo-rubber* be obtained by treating rubber hydrohalides with Zn, but it is formed by heating rubber in the absence of air with acids, or by distn. at atm. pressure. The derivs. of natural rubber, of synthetic rubber, of gutta-percha and of balata are identical, in each case the colloid mol. having suffered degradation to such an extent that any differences in the original 4 substances no longer exist. Accordingly the differences in the properties of rubber, gutta-percha and balata are due solely to differences in the constitution of the colloid mols. The rubber mols. are the largest and so rubber solns. have higher viscosities than gutta-percha or balata solns. of the same concn.

C. C. DAVIS

The concentration of latex with the aid of the filtration apparatus of Bechhold-

König. RUDOLF DITMAR. *Caoutchouc & gutta-percha* **23**, 13,010-1 (1926).—Without the use of collodion, the Bechhold-König filtration app. gives excellent results in the concn. of latex (cf. Ditmar, *C. A.* **20**, 311). On the other hand the method of Traube (German Patents 414,210 and 414,930) is uneconomical on a large scale. C. C. D.

Effect of accelerators on the temperature of rubber mixtures. F. KIRCHHOF. *Rubber Age* **18**, 355-7 (1926).—English version of a previous article (*C. A.* **19**, 2424) C. C. DAVIS

Coloring rubber (Brit. pat. 242,274) **26**. Action of N_2O_4 on caoutchouc (Emden) **10**

Rubber compositions. C. PICKSTONE. Brit. 241,993, July 31, 1924. State powder 40-70, rubber (which may be partly reclaimed rubber) 15-25, bitumen 2-10 and vulcanizing and coloring materials 13-25% are mixed in the powd. state, molded, pressed and vulcanized.

Preserving rubber. T. W. K. CLARKE. Brit. 242,096, Dec. 1, 1924. Tires or other rubber articles are coated with a mixt. formed of china clay 30, soft soap 60 and chrome yellow 10 parts, mixed with H_2O to a paste or paint, or with a similar mixt. which excludes actinic light from the rubber.

Repairing rubber articles. W. H. BUSCHELL. U. S. 1,573,039, Feb. 16. A portion of rubber to be repaired, e. g., a cut or blown-out tire, is heated and treated with a reaction product obtained by "natural valence combination" of turpentine and S. The article is then further subjected to the action of heat and pressure.

Treating rubber latex. W. B. WESCOTT. Brit. 236,624, April 7, 1924. Latex is concd. to a thick mass in which the rubber remains uncoagulated by intense centrifuging with as little agitation as possible. An alk. stabilizing substance is preferably added to the concd. latex as it emerges from the app. Details of an app. for this purpose are specified.

Coagulating latex. H. W. HAMMOND. Brit. 236,633, April 8, 1924. A soln. obtained from cane molasses by dilg., clarifying and boiling (or other saccharine soln.) is added to rubber latex, and the mixt. is boiled to effect coagulation.

Thin-walled rubber receptacles, etc., formed from sheets of coagulum or plastic rubber. A. R. VAN DER MARK and H. KREMER. Brit. 236,897, July 11, 1924. Mech. features of molding, etc.

Rubber playing balls. R. RUSSELL and H. BROOMFIELD. U. S. 1,573,093, Feb. 16. A tennis ball or the like composed of sections of vulcanized rubber is provided on at least one side with a film of pptd. latex solids.

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

An improved all-metal mercury-vapor pump. G. W. C. KAYE. *Phil. Mag.* [7] 1, 349-53(1926).—An all-metal single-stage Hg-vapor pump is described with a detail drawing of the pump and an accessory needle-valve to control the inlet of air for a controlled vacuum. The walls are of solid drawn-steel tubing $\frac{1}{16}$ in. thick. The jet is of the annular type $\frac{1}{32}$ in. in width. Either elec. or gas heating may be used up to 600 v. or 12 l. of coal gas per min. A back pressure of 4-5 mm. is allowable and 15 mm. is sufficient to give the highest attainable vacuum. Only 50 cc. of Hg is required and as a result of the low heat capacity, the pump will operate, with gas, in 3 min. from cold. The micrometer needle valve, shown in detail, is a steel needle in a narrow brass seat. S. C. LIND

Foam meter. H. E. WILLIAMS. *Ind. Eng. Chem.* 18, 361-2(1926).—The substance under test is placed in a vertical cylindrical container and agitated at a standard speed for a definite length of time, when a cock in the bottom is opened and the contents are allowed to fill a standard flask, whose vol. is considerably less than that of the liquid taken for the test, the flask then being weighed. Obviously the greater the foaming tendency of the liquid under test the higher will be the proportion of air in the mixt. drained from the app. and the less will be the wt. of the flask and its contents. W. B. PLUMMER

A support for the condensation of sublimates. A. BRALEY. *Bull. soc. franç. mineral.* 48, 92-5(1925).—An apparatus for the analysis of Hg, Se, As and similar materials. C. B. SLAWSON

A device for circulating fluids under high pressure. I. R. MCHAFFIE. *Trans. Faraday Soc.* (advance proof), Feb. 22, 1926.—An electro-magnetically operated pump for circulating gases at high pressures and const. rates. A detailed description and diagram are given. ARTHUR GROLLMAN

Production and measurement of high vacua. H. H. PAINE. *J. Chem. Met. Soc. S. Africa* 25, 341-50(1925).—Complete descriptions are given of the theory and operation of the Gaede mol. pump, the Gaede Hg-vapor diffusion pump, and the Langmuir pump, and of the McLeod and Pirani gages. T. S. CARSWELL

The accuracy of gas-measuring vessels. H. V. RENN. *Ind. Chemist* 2, 54-6(1926); cf. *C. A.* 20, 847.—The article deals with the calibration of cylindrical glass tubes and burets to be used in gas analysis. Because of the difficulty of constructing a tube closed at both ends by stopcocks, so that it will contain exactly 100 cc., it is usual with such instruments to graduate them on the basis of an arbitrary unit, usually $\frac{1}{100}$ of the total vol. When the arbitrary unit method is employed it is a rule of the National Physical Lab. that the value of this unit must be inscribed on the app. R. describes in detail the precise calibration, by means of Hg, of gas tubes, including tables for use in making corrections for the errors due to water and mercury menisci. With H₂O as the confining liquid, R. gives a detailed description of the calibration of similar tubes with the use of a 2-cc. or 5-cc. Ostwald pipet. Lunge's statement (*Technical Gas Anal.*) that "the examn. of app. adjusted for Hg, especially when they are provided with a stopcock, can be performed by means of water, from the tables worked out for volumetrical vessels" is incorrect if dry Hg is to be used. Vessels intended for use with dry Hg cannot be tested with H₂O in the ordinary way, for in so doing a film of H₂O is left on the walls, thus escaping measurement. E. G. R. ARDAGH

An automatic siphonic gas circulator. G. M. GREEN. *J. Chem. Soc.* 1926, 500.—Two concentric glass tubes, about 6 ft. long and 1 in. in diam., one fitting inside the other loosely enough to allow the passage of water, are connected with a siphon tube, and gas outlet and inlet regulated by mercury seals. The inflowing water fills the tubes, forcing

out the enclosed gas. When the tubes are filled with water, the siphon commences to operate and empties them of water, while a new vol. of gas is sucked in. Intermittent circulation of gas is thus maintained. R. J. HAVIGHURST

Spiral springs of quartz. H. D. H. DRANE. *Nature* 116, 315(1925).—A method is described for the production of spiral springs of silica fibers having a diam. of about 10^{-3} cm. (cf. Smith, C. A. 20, 521). B. C. A.

Small constant-humidity testing cabinet. F. T. CARSON. *Paper Trade J.* 82, No. 8, 231-7(1926).—A cabinet is described in which paper can be tested without opening the cabinet to the outside air at any time. Air is taken from the cabinet through a blower at the rate of about 1 cu. ft. a min., is bubbled through H_2SO_4 of proper concn to maintain the desired relative humidity, and is then returned to the cabinet. The tester is placed inside the cabinet, which normally has no communication with the outside air. The specimens are handled and the tester is manipulated by means of flexible sleeves which terminate in rubber gloves into which the hands are placed. The method of operation is described in detail. The difficulties encountered, mainly possibility of variations in the relative humidity due to differences in the temp. of the air in the cabinet and of the H_2SO_4 , are discussed. A. PAPINEAU-COUTURE

The Brown-Duvel moisture tester and how to operate it. D. A. COLEMAN AND E. G. BOENER. U. S. Dept. Agr., *Bull.* 1375, 1-44(1926).—A detailed description of the Brown-Duvel moisture tester and of its application in the detn. of moisture in grain, flour, meal and other materials. W. H. ROSS

New apparatus for the determination of water. H. KREIS. *Ann. chim. anal. chim. appl.* 8, 33-4(1926).—The app. is similar in principle to that of Normann (C. A. 19, 2277). Also in *Schweiz. Apoth. Ztg.* 63, 671-2(1925). W. T. H.

Proper methods of installing electric pyrometers. MAX MOELLER. *Siemens Z.* 6, 65(1926). C. G. F.

Theory and construction of lever manometers. OTTO FRANK. *Z. Biol.* 83, 1-15(1925).—F. discusses the theory and construction of lever manometers. If the vol. elasticity coeff. equals infinity a system which has 2 degrees of freedom is obtained. This system possesses the essential properties of a lever manometer. The chief data may be calcd. to within 1%. FRANCES KRASNOW

Generation of ultra short waves. V. J. SHAROV AND N. A. PETROV. *Elektrichest.* 1926, No. 1, 44-9.—Report of an exptl. investigation of thermionic valves. C. G. F.

Modern refrigerating machines, their manipulation and advantages. CONSTANTIN REDZICH. *Apparatebau* 37, 117-8, 129-31, 141-3, 153-4, 169-70, 184-6, 195-6, 207-9, 229-31, 244-5, 256-7, 275-6, 288-9, 298-9, 312-3, 324-6, 334-5(1925). 28, 1-3, 13-6, 25-7, 37-9(1926); 29 cuts.—Many data on operating costs and capacities are given. J. H. MOORE

Bibliography of antimony, from 1917 to 1924. C. Y. WANG. *J. Assoc. Chinese American Eng.* 6, No. 3, 14-34(1925). W. H. A.

The early use of zinc in China. H. D. DJANG. *Science (China)* 9, 1116-27(1924). cf. *C. A.* 18, 487.—Further evidence from early writers and analyses of ancient coins suggests that the Chinese possessed a knowledge of the use of zinc in alloys previous to its traditional discovery by the Persians. Its use in China certainly did not date later than its use in Egypt and Rome. WM. H. ADOLPH

Ancient Chinese brass. C. WANG. *Science (China)* 10, 495-503(1925).—A study of the compn. and method of manuf. of the famous brass of the Ming dynasty. WM. H. ADOLPH

The analysis of Chou Dynasty alloys. T. LIANG. *Science (China)* 9, 1261-78(1925).—Analyses of alloys from the period 1100 to 300 B. C. verify the ancient records in their compn. WM. H. ADOLPH

The discovery of aluminum. NIELS BJERRUM. *Z. angew. Chem.* 39, 316(1926).—Oersted, in 1825, was the first to prep. Al. E. H.

A device for constructing models of carbon compounds. W. H. DORE. *J. Chem. Education* 3, 319-23(1926). E. H.

The evolution of chemical terminology. IX. Pectization and peptization. J. F. COUCH. *Am. J. Pharm.* 97, 858-61(1924); cf. *C. A.* 19, 339.—The obsolescent *pectization* should be let go and *peptization* limited "to that type of gel-sol transformation in which the addition of an electrolyte is necessary to effect the change." A. M. P.

The use of subscript and superscript exponents in chemistry. E. Q. ADAMS. *J. Am. Chem. Soc.* 48, 708(1926).—A. advocates the use in arithmetic and chemistry (as in logic and higher math.) of subscripts as a means of designation and of superscript to denote repetition. D. S. VILLARS

The non-metallic elements. Connections between their dielectric and other physical properties. II. G. L. ADDENBROOKE. *Phil. Mag.* [7] 1, 225-43(1926). Comparison is made between the dielec. const. and the optical properties in the liquid and gaseous states of the elements H, He, O₂, N₂, Cl₂, Br₂, I₂, P, S, Se and in the solid state for C (diamond). S. C. I.

Determination of Avogadro's constant by means of birefringent solutions of dialyzed iron. L. TIERI. *Nuovo cimento* [N. S.] 2, 351-61(1925).—The solns. used contained ultramicroscopic particles of a single species of granule. Some of the liquids exhibited a piling up of granules at the bottom and hence a greater birefringence for the lower strata than would follow from Laplace's law. This was particularly marked in one case. Values for Avogadro's const. ranged from $N = 66 \times 10^{22}$ to $N = 50 \times 10^{22}$. L. T. FAIRHALL

The crystalline structure of cadmium and nickel hydroxides. G. NATTA. *Atti accad. Lincei* [6] 2, 495-501(1926).—The hydroxides of Zn and Co are known to have a rhombic symmetry and those of Mn, Fe⁺⁺, Mg and Ca are rhombohedral. Nothing is known about the structure of the other hydroxides of bivalent metals. The method of Debye and Scherrer was applied to Ni(OH)₂ and Cd(OH)₂. Both were found to belong to the rhombohedral system. The results for these and 3 other hydroxides found in the literature are tabulated below:

Metal	At. diam. of metallic ion	Vol. of the cell of the hydroxide	<i>a</i>	<i>c</i>	<i>c/a</i>
Ni	2.70	37.6	3.07	4.605	1.50
Mg	2.85	39.8	3.11	4.73	1.52
Mn	2.95	46.5	3.34	4.68	1.40
Cd	3.20	49.0	3.47	4.64	1.355
Ca	3.40	52.95	3.52	4.93	1.40

E. J. WITZEMANN

The molecular weight of soluble starch. AMÉ. PICTET. *Helvetica Chim. Acta* 9, 33-7(1926).—By accepting +189° as the av. *sp. rotatory power* of sol. starch, its mol. wt. is calcd. to be 2975. This calcn. assumes the relation between *rotatory power* and *mol. wt.* of the ultimate depolymerization products of starch to be applicable to as complex a deriv. as sol. starch. The simplest mol. of sol. starch is, therefore, (C₆H₁₀O₅)₁₈, i. e., a condensation of 3 mols. of *hexahexosan*. ARTHUR GROLLMAN

Corrections to my work: Previously unknown characteristics of simple compounds and considerations on the form of the solid state. ERNST FRIDRICH. *Z. Physik* 34, 637(1925); cf. *C. A.* 19, 1644. H. C. UREY

The effect of rolling on the crystal structure of aluminum. E. A. OWEN AND

G. D. PRESTON. *Proc. Phys. Soc. (London)* **38**, 132-47(1926) — Sheets of Al were examd. by the ionization spectrometer and X-ray photographic methods. When a cast specimen of Al contg. large crystals oriented at random is rolled, the crystals break up into a large no. of min. crystals. These small crystals assume a definite orientation, each crystal having a cube diagonal [111] plane in the direction of rolling and a (211) plane in the surface of rolling. Two sets of crystals exist in the material after rolling, one set being the optical image of the other in the plane of rolling. The lattice parameter of the severely worked material does not differ from that of the annealed material by more than 0.5%. These results confirm those of Wever (*C. A.* **19**, 10). R. J. H.

Structure of α quartz. R. E. GIBBS. *Proc. Roy. Soc. (London)* **110A**, 443-55 (1926); cf. *C. A.* **19**, 1644; **20**, 318. — A study of the intensities of reflection of X-rays by the various planes of α quartz has been made with the aid of oscillation, rotation and Laue photographs and ionization spectrometer measurements. The O atoms occupy positions $c/9$ above and below the basal planes which contain Si atoms. The proposed structure assumes the crystal to be non-molecular and requires a shift of the Si atoms of about 0.3 Å U. from the positions occupied by them in β quartz. The tetrahedral arrangement of O atoms around each Si atom, which was found in β quartz, is distorted in α quartz. R. J. HAVIGHURST

Volume variations in the formation of solid inorganic compounds. E. MOLES. *Anales soc. españ. fís. quim.* **23**, 524-39(1925). — With the work of Ephraim (*C. A.* **13**, 1660; **18**, 1770, 2448), and Biltz (*C. A.* **15**, 2025, **16**, 1195) as a starting point the vol. changes during formation of permanganates and chlorides of a large no. of elements were investigated. The vol. variation is expressed by $VM/\Sigma V.A.$, VM being the mol. vol. deduced from the d. by $VM = PM/d$ and $\Sigma V.A. =$ the sum of the at. vols. of the components. For solid compds whose m. p. is far different from ordinary temp. the d. at this temp. was used. For those readily fusible or liquid or gaseous at ordinary temp. the d. was reduced to abs. zero by the R. Lorenz formula. This is justified by recent results by van Laar (*C. A.* **20**, 1008), and Biltz, which permits comparison of mol. vols. under corresponding conditions. A no. of errors made by Zaslavskii (*C. A.* **19**, 3392) were found. Vol. changes, arranged according to electropos elements in the periodic system, show (a) In chlorides showing a vol. contraction the heat of formation per atom of Cl is above 50 cal. In all cases of dilation it is below 50 cal. (b) Chlorides can be divided into 3 groups according to the vol. change, namely those showing a diminution, a dilation and an intermediate group. (c) With chlorides of the first group the contraction increases with the at. wt. of the metal. In the second group dilation increases with the at. wt. of the metal. With chlorides of the transition elements such as group VIII, rare earths and sub-groups Ib and VIIa, const. values are obtained. These laws allow of calcn. of unknown at. vols. as a function of the known mol. vol. and of the variation in the vol. of the chloride. The variations of the permanganates are practically the same as those of the chlorides. The mol. vols. of metal carbonyls give for the mol. vol. of CO values almost normal with Ni and Co. For Fe the value is a little lower, according to the method of decompn. The CO in carbonyls thus follows the law of addn., like NH_3 in amines and H_2O in hydrates. The mol. vols. of a no. of cobalt-amines show that entrance of NH_3 , H_2O and Cl into the nucleus follows the rule of addn. E. M. SYMMES

Molecular volume of water in crystalline hydrates. E. MOLES. *Anales soc. españ. fís. quim.* **23**, 557-85(1925) — Expts. proved the existence of hydrates of cations and anions, as foreseen by the Werner theory. With chlorides, sulfates, nitrates, nitrites and double sulfates whose hydrates have been well studied, the mol. vol. of the H_2O of the cation is 14.6, practically coinciding with the calcd. value of 14.3 for zero. abs. For amines the vol. of the H_2O of hydration is always very near 10. Almost the same value is found for H_2O combining with anhydrides and oxides to form acids and bases. There is only 1 remarkable exception, the phosphoric and phosphorous acids, in which the mol. vol. of the H_2O approaches that of the cations. This, together with exptl. data on these acids and salts, establishes the formula H_3PO_3 . The H_2O mol. is held in

HOH

a labile form by a covalence. In all monohydrate salts the H_2O mol. is found as the hydrate of the anion. In the acids the H-ion can also give hydrates whose index of coordination is a max. of 1. Salts of the rare earths are the only exception to the above rules. The double sulfates and nitrates of these cations give 3 as the max. for hydration of the cation. The vitriols have 7 H_2O mols., 6 belonging to the cation and 1 to the anion. The thermic values are in exact agreement with the above. The probable existence of hydrates of the cation with an index of coordination of 5 for the sulfates

of the vitriolic metals was detd. For tervalent metals of the alums the existence of hydrates with 12 H₂O mols. was detd., agreeing with the Pfeiffer view. E. M. S.

Solid solutions between compounds of elements with different valences. G. BRUNI AND A. FERRARI. *Atti accad. Lincei* [6] 2, 457-62(1925).—The isomorphism of LiF and MgF₂ was studied with X-rays by Bruni and Levi (C. A. 19, 2581) and by Ferrari (C. A. 19, 2890). The system MgCl₂-LiCl of which the miscibility in the solid state was detd. by Tacchini (C. A. 19, 1368) was studied. The results show that anhydrous MgCl₂ gives a photogram by the method of powders corresponding to a cubic lattice coinciding with that of LiCl. The elementary cell contains 2 mols. MgCl₂ and corresponds to that contg. 4 mols. LiCl. The fundamental data of the 2 cells follow: for 4 LiCl and 2 MgCl₂ $a = 5.10$ A. U. and 5.09 A. U., vol. = 132.65 A. U., and 131.87 A. U., calcd. d. 2.12 and 2.47 , observed d. 2.06 and 2.32 , resp. Since anhyd. MgCl₂ is uniaxial birefringent it has a pseudocubic structure belonging to 1 of the tetragonal or hexagonal systems. E. J. WITZEMANN

The allotropy of zinc. DAVID STOCKDALE. *J. Chem. Soc.* 127, 2951-6(1925).—For detecting the presence and the temp. of allotropic change in Zn an electrolytic cell was used which consisted of Zn electrodes in the arms of a hard-glass U-tube filled with a molten electrolyte (m. about 280°) of ZnCl₂, contg. much oxychloride, plus 10% ZnBr₂. One electrode was kept $6-15^\circ$ hotter than the other, thereby giving rise to an e. m. f. between them; and this e. m. f. was recorded continuously while the whole cell was heated or cooled through the suspected temp. of allotropic change. The occurrence of an allotropic change in either Zn electrode was indicated by a break in the e. m. f.—temp. curve of the cell. The expts. indicate fairly convincingly that Zn undergoes an allotropic change at 315° . Miss Bingham (C. A. 14, 3341) found changes in certain properties of Zn at 330° and 310° . R. H. LOMBARD

Transition compounds between those having a saline character and the metallic alloys. M. PADOA. *Gazz. chim. ital.* 55, 975-83(1925).—The modern theory of valence based on electrochem. processes is adequate for all compds. having a saline character but the problem changes when one considers the intermetallic compds. Ordinary valence does not serve to explain the stoichiometric ratios and the characteristics of metallic alloys are not those of saline compds. Some years ago P. and Zanella (C. A. 17, 1564) suggested that compds. between metals are formed through the secondary valences. In extending this work P. has considered that since As has definite amphoteric characters the arsenides ought to be intermediate between saline and intermetallic compds. Some of the metallic sulfides are undoubtedly saline compds. (e. g., Na₂S, K₂S) while others like FeS₂, ZnS and PbS are even metallic in appearance and Trümpler (C. A. 16, 675) says that these contain the metals in the neutral state. P. investigates As₃Sn₂, As₃Sn and As₃Sn₃. He concludes that compds. of elements of the intermediate type with metals have the properties of metallic alloys and of saline compds. at the same time. The existence of an equil. between the saline form (ionized) and the metallic form is to be expected. This equil. is changeable with the temp. so that the existence of a temp. at which the cond. will reach a max. value for each compd. is to be expected. The above arsenides were prepd. in the form of bars and their elec. resistance was measured at various temps. From these detns. it was found that this max. is 25° for As₃Sn, 0° for As₃Sn and -20° for As₃Sn₃. E. J. WITZEMANN

The hydration water of crystalline compounds. A. GH. BERGHMAN. *J. Russ Phys.-Chem. Soc.* 56, 177-232(1925).—The purpose of the paper was to furnish evidence of the analogy between vapor tension and the elec. potential of metals. The theoretical and exptl. aspects of vapor-tension methods as applied to the study of hydrates are discussed. Van Bemmelen's method, being the most reliable and expedient, was used for the study of vapor tensions at 15° of 16 systems (anhyd. salt-water): CuCl₂, Na₂S₂O₈, Na₂PtCl₆, K₃[Co(C₂O₄)₃], K₃[Cr(C₂O₄)₃], Na₃[Cr(C₂O₄)₃], [Co(en)₃]Cl₃, [Co(en)₃]Br₃, [Co(en)₃]I₃, [Co(en)₃][Cr(C₂O₄)₃], [Co(en)₃][Co(C₂O₄)₃], NiCl₂[Co(en)₃]Cl₃, Ca(UO₂)₂(PO₄)₂, Co(UO₂)₂(PO₄)₂, Cu(UO₂)₂(PO₄)₂, Co(UO₂)₂(PO₄)₂. Conclusions: Cryst. hydrates have 2 vapor tensions. The one which is usually observed and detd. represents the vapor tension of the efflorescent crystals. The other is considerably lower ($1/7_{10}$ as great for CdSO₄) and belongs to the intact crystals. The hydration water of [Co(en)₃][Cr(C₂O₄)₃] is subject to rules different from those of the other salts. MARY JACOBSEN

Kinetic theory of the specific heat of solutions. NICOLA DE KOLOSOSKII. *Gazz. chim. ital.* 55, 844-58; *J. chim. phys.* 22, 225-52(1925).—In a series of nine papers (four of which were published in 1925 and five of which were in press) K. developed a general theory of the sp. heat of solns. by following in the steps of van't Hoff and applying to liquid solns. the consequences of the kinetic theory of gases. This paper constitutes a résumé of the essential part of these papers and also contains some new exptl. data

K. considers 5 hypotheses: (1) The sp. heat of a soln. is composed additively of the sp. heats of all the components of the system; (2) the sp. heats of the dissolved mols. and of the ions are equal to what they would be if in the state of gas; (3) the mol. heat of a n -atomic gas may be expressed by the formula $C_p = 2n + 3$; (4) the passage of a part of the solvent into the state of chem. combination with the mols. or the ions of the dissolved substance is accompanied by a certain variation of the sp. heat; (5) when a rise in temp. is brought about in a soln. a certain quantity of heat is spent in accomplishing the work necessary to overcome the viscosity of the medium. These are considered in detail. It is concluded that the sp. heat of a soln. is composed of the heat spent in raising the temp., of that that is transformed into external heat, and finally of that corresponding to the internal work (work of friction or of viscosity). The same conclusions ought to be applicable to the sp. heat of pure compds. The problem is more difficult in this case, upon which K. is now working. E. J. WITZEMANN

Physicochemical properties of hydriodic acid gas. R. MIRAVALLES AND E. MOLES. *Anales soc. españ. fis. quim.* 23, 509–23(1925).—HI was prepd. from the elements and the pressure of its satd. vapor detd. between -56° and -35° . The normal b. p. was found to be -36.0° , the m. p. -50.0° . A Pt thermometer was used, and a paraffin-oil compensator to isolate the manometers from the receiver because HI attacks Hg even when dry. Vapor pressure is represented by $\log p = 7.20833 - 1025.71 \times 1/T$, which is a straight line. The results approached those of Steele and McIntosh (*Z. physik. Chem.* 55, 136(1906)), and Henglein (*C. A.* 18, 186), but were slightly higher. The b. p. is a little lower, the m. p. slightly higher, than the av. of previous results, which indicates that an impure gas had been used previously. Almost all the previous data have been obtained on HI made by hydrolysis of PI_3 , which was found to give an impure gas. From the above data the mol. heat of evapn. was calcd. as 4916 cal. The Nernst formula gave 20.74 and 20.90 for the Trouton const., and HI is therefore a normal substance. The Guye-Guldberg law gives $T_e = 1.73 \times T_c$ as 410 for the crit. temp., agreeing closely with tests. From m. p., b. p., and heat of evapn., in connection with the same consts. for the corresponding noble gas it was found that HI behaves perfectly normally. E. M. SYMMES

The movement of a perfectly compressible fluid (French). A. FRIEDMANN AND B. IZVEKOV. *Bull. acad. sci. Russie* 19, 351–62(1925).—Math. discussion of the equations of Lagrange and Euler in connection with phenomenon of the movement of fluids. J. S. JOFFE

The rule of Duhem-Margulés. N. ZAVARITZKII. *J. Russ. Phys.-Chem. Soc.* 56, 367–71(1925).—The validity of the relation of Duhem-Margulés between partial pressure and compn. of the liquid phase in binary mixts.: $(d \ln p_i)/(d \ln x) = (d \ln p_i)/[d \ln(1 - x)]$ was studied for the systems HCl-H₂O and HBr-H₂O with the aid of the exptl. material of Zavaritzkii *et al.* (*C. A.* 18, 1421). It was found to be valid for systems contg. from 0 to 30% HCl and from 0 to 55% HBr, resp. The higher concns. were not studied because of the lack of reliable exptl. data. MARY JACOBSEN

Molecular mechanics. R. CASARES. *Anales soc. españ. fis. quim.* 23, 551–6(1925).—An intramol. force of attraction inversely proportional to the square of the distance is assumed. Taking into consideration the thermic movement a hyperbolic law is arrived at, expressing the relation between the mol. distance and the temp. of equil. of a liquid and its vapor. In certain cases this law is approx. verified if a proper origin of temp. for each substance is taken. E. M. SYMMES

A method of measuring the relative surface charges on electrolytes. ALLEN GARRISON. *J. Phys. Chem.* 29, 1517–22(1925).—A new method of obtaining the relative magnitude of the charges on the surfaces of solns. to within 0.01 v. is given. The surface of the soln. is made one plate of a condenser. A disk of Cu coated with Pd is held parallel to the surface and forms the second plate. The potential of the Cu disk is adjusted by an accurate potentiometer until motion of the disk with respect to the surface produces no deflection in a quadrant electrometer connected to both disk and soln. The disk is then at the same potential as the surface. Contact between soln. and electrometer is made through a HgCl electrode. The surface charges of a number of electrodes have been measured, pure water being taken as the standard of reference. The first traces of a substance added to water produce the largest effect. Subsequent addns. have small effect, generally reducing the charge and sometimes reversing its sign. The general relations between concn. and surface charge resemble those between concn. and adsorption. R. E. GIBSON

A comparison of methods of measuring the polarity of surfaces. N. K. ADAM, R. S. MORRELL AND R. G. W. NORRISH. *J. Chem. Soc.* 127, 2793–5(1925).—"Polar" and "non-polar," as here used, refer to the tendency of a substance to dissolve in H₂O,

or in hydrocarbon solvents, resp. Varnishes which "bloom" in H_2O ought to be more polar than non-blooming varnishes. The relative polarity of surfaces of glass, blooming and non-blooming varnishes, paraffin wax, and stearic acid was detd. by measuring their catalytic action on dry ethylene + Br_2 , and on moist ethylene + Br_2 ; and by detg. their angle of contact with H_2O , this being a measure of their attraction for H_2O . The varnishes which are more polar by the angle of contact method are also more polar by the catalytic method. The attraction of a varnish for H_2O parallels its veiling properties. If the attraction is more than about 70% of that of H_2O for itself, the varnish veils, if less than 45-50%, it does not veil. There is, however, considerable disagreement between the polarities of surfaces of different kinds as measured by the catalytic method, and by the angle of contact method; e. g., glass has less catalytic power than stearic acid or the veiling varnishes, but much greater attraction for H_2O . This difference may be due to the "surface" of the more catalytic substance having a depth of several mol so that by penetrating to this depth it would be possible for gases to reach a greater no. of polar groups than are to be found on an equal area of glass. R. H. I.

The adsorption of sulfides by colloidal chromium hydroxide. H. N. HOLMELAND M. A. DIETRICH. *J. Am. Chem. Soc.* **48**, 678-82(1926).—Pptn. of certain sulfides by H_2S in 0.5 N HCl soln. contg. $CrCl_3$ may be prevented by adsorption of the sulfide by colloidal $Cr(OH)_3$ formed by hydrolysis. This occurs in freshly pptd. solns. contg. $CrCl_3$ and $HgCl_2$ in excess of the ratio 2:1. Hydrolysis increases markedly on standing. Sufficient concns. of H^+ and of SO_4^{--} retard the hydrolysis. In $Cr_2(SO_4)_3$ solns. hydrolysis is so slight that there is no interference with the pptn. of the sulfides. Solns. in which marked hydrolysis has occurred are reversed by boiling them for 2 min. after making 3 N with HCl. These facts must be considered in connection with *Sneed's method of qual. analysis* for the H_2S group. F. L. BROWNE

The adsorption of gases by activated charcoal at very low pressures. I. At air temperature. H. ROWE. *Phil. Mag.* [7] **1**, 109-31(1926).—A method is described for detg. the quantities adsorbed by activated charcoal at very low pressures. Results have been obtained for N_2 , CO , O_2 and CO_2 at air temps. From a consideration of the adsorption isotherm of these gases, it is shown that this is better represented by $\log \alpha/P = A_0 - A_1\alpha$ than by the more usual equation $\alpha = kP^{1/n}$. At very low pressures the value of A_1 is negligible compared with that of A_0 , and the relationship between α and P is linear. The pressure at which this relationship no longer holds varies with the b. p. of the gas; it decreases as the b. p. increases. S. C. I.

A method for determination of the adsorption of ions on colloidal particles by means of Donnan's membrane equilibrium theory. HERMAN RINDE. *Phil. Mag.* [7] **1**, 32-50(1926).—R. attains a condition of Donnan equil. by rendering one of the electrolytic ions non-dialyzable by adsorbing it on colloidal particles too large to dialyze. Colloidal S was used to adsorb HCl. In this way the same condition was realized and the same formulas were found to apply as if the HCl itself had been non-dialyzable. By means of a quinhydrone electrode, the e. m. f. of the cell was measured, as also the osmotic pressure. The curve for osmotic pressure has the same shape, but instead of approaching zero attains a low const. value which could not be identified as the osmotic pressure of the colloid itself. S. C. I.

The sorption of vapors by alumina. L. A. MUNRO AND F. M. G. JOHNSON. *Phys. Chem.* **30**, 172-88(1926).—M and J have previously shown that alumina takes up a greater amount of H_2O than of any other vapor (*C. A.* **19**, 759). In the present paper the sorption of water vapor by alumina gel at various temps. and pressures is studied. Both Freundlich's and Patrick's equations apply to the sorption isotherms for 60° and 80°, while neither equation applied to the isotherms obtained when the partial pressures approach the vapor pressure of the H_2O at the temp. of the sorbent. Trouton's sorption rule holds approx. over the temp. range studied, i. e., 35.5° to 80°. PER K. FROLICH

Velocity of crystallization of sucrose from pure aqueous solutions at 60°. I. A. KUCHARENKO AND M. I. NACHMANOVICH. *Centr. Zuckerind.* **33**, 1609-10(1925); *Zapiski* **1924**, 173.—The difficulties of crystn. expts. at high temps. are (a) danger of cracking the original crystals during heating, (b) danger of cracking during cooling after the expt., (c) difficulty of removing the adhering film of soln. at the end of the expt., (d) error due to the fact that expts. are short and the time necessary to remove the crystal is a large % of the total, (e) difficulty of completely removing nuclei from the supersatd. soln. K. and N. have overcome these, but the means used are not given. A large no. of expts. detd. a curve, from which the following values are read for rate of crystn. (a) of sucrose, from solns. of known supersatn. (b), at 60°: (a) 340, (b) 1.005, (a) 720, (b) 1.010; (a) 1340, (b) 1.015; (a) 2210, (b) 1.020; (a) 3100, (b) 1.025. W. L. B.

The rate of solution of sucrose in nearly saturated solutions. I. A. KUCHARENKO AND M. I. NACHMANOVICH. *Centr. Zuckerind.* **33**, 1587-8(1925); *Zapiski* **1924**, 180.—The rate of soln. of a crystal may be written $x = \Delta P/St$, where x is the rate of soln., ΔP is loss in wt., S is surface and t is time. This may be written $x = \Delta P/(K\sqrt[3]{P^2t})$, where P is the mean wt. of the crystal during the process. In general K is not known. Expts. with weighed sugar crystals gave a value of xK (in mg. per sq. m. per min. at 20°) of 20,303 in a soln. 98.96% satd.; 35,479 at 98.13% and 59,649 at 97.54%. If perfect crystals were used K could be calcd. from actual measurements; but during soln. the crystal becomes etched so that the surface cannot be calcd. and hence K is uncertain. K. and N. have detd. the rate of crystal growth for sucrose at 20°. Hence if an etched crystal were grown in a sugar soln. of known supersatn. at 20°, its increased surface could be calcd. from its increased rate of growth. The difficulty is that in growing etched crystals, the first growth tends to restore the regular surface before general growth takes place. Seven such expts. with etched crystals growing in a soln. of 1.025 supersatn. at 20° gave a growth of 504, 335 and 448 mg. per sq. m. per min. for the first 70 mins., and 269, 265, 303, 269 mg. per sq. m. per min. for the first 125 mins. This work is to be continued.

W. L. BADGER

Influence of temperature on the reciprocal solubility of the monoalkyl ethers of ethylene glycol and water. H. L. COX AND L. H. CRETCHER. *J. Am. Chem. Soc.* **48**, 451-3(1926).—Complete soly. data are given for BuOCH₂CH₂OH and iso-BuOCH₂CH₂OH and H₂O; these compds. possess completely closed soly. curves. C. J. W.

The preparation of diluted from concentrated solutions. EMIL LÖW. *Mikrokosmos* **19**, 99-101(1926).—A simple computation permits the prepn. of dil. solns. of a definite content when the concn. is given in g. per 100 cc.

EMIL KLARMANN

The activity coefficients of hydrochloric acid in glycerol-water mixtures. W. W. LUCASSE. *J. Am. Chem. Soc.* **48**, 626-31(1926).—The activity coeff. of HCl is calcd. from the e. m. f. of the cell H₂ | HCl(x M) | AgCl | Ag. x varies from 0.001 to 4 and the solvent is a mixt. of glycerol (1 and 5 mol %) in water. This observed activity coeff. agrees well with that calcd. from the Huckel equation (cf. *C. A.* **19**, 1649) for concns between 0.001 and 1.0 M, but not for higher concns.

D. S. VILLARS

The electrode potential of mercury against its ions in aqueous methanol, acetone, and pyridine. J. GHOSH, P. R. CHAUDHURI AND A. SEN. *J. Indian Chem. Soc.* **1**, 189-200; *Science Abstracts* **28A**, 487-8(1924).—Measurements are made of the abs. potential of Hg in different solns. contg. its ions by detg. the max. position of the electrocapillary curve. From the Lippman-Helmholtz original equations the following relation is derived: $\gamma = \gamma_{\max} - \frac{1}{2}CE^2$, where γ is the surface tension of Hg, C the capacity of unit area of the double layer, and E the p. d. at the boundary. Measurements are made with a U-tube capillary electrometer, to which definite potentials are applied, and the Hg meniscus is read with a microscope. The residual currents corresponding to definite polarization voltages are investigated. The tendency of the electrolyte to creep between the glass wall and the Hg column, thus causing a variation of the capacity of the double layer, is checked as far as possible. A considerable influence on electrocapillary effects appears to be exerted by the adsorption of ions by the Hg surface. With an aq. soln. of HNO₃ and HgNO₃ a fairly good parabolic curve, as demanded by the equation, is obtained with a max. at 1.05 v. This detn. agrees with the value of 0.391 found for the e. m. f. of Hg in this electrolyte against a calomel electrode of which the single p. d. is taken as 0.612. Measurements are made in aq. mixts. of MeOH, acetone and pyridine, and a detn. is made of the dielec. const., D . The potentials E fall with diminishing content of water. With MeOH and water mixts. contg. over 50% of the latter an approx. const. value of about 0.93 is obtained for E/D . In aq. acetone an abnormally low value of the potential is given with a 20% acetone mixt., but with this exception the ratio E/D remains const. at about 1.25 up to 40% acetone and thereafter increases. With pyridine-water the ratio E/D is practically const. at about 0.75 within the range 10 to 40% of pyridine. Within a certain range the free energy of the mercurous ion is in the proportional to the dielec. const. Cf. Kruger and Krumreich, *C. A.* **7**, 3896.

H. G.

The activity coefficients of several types of electrolytes calculated from freezing-point data. W. H. RODEBUSH. *J. Am. Chem. Soc.* **48**, 709(1926).—The activity coeffs. of 0.001, 0.005 and 0.01 M solns. are calcd. from the f. p. data of Hovorka (cf. *C. A.* **19**, 2439). They are, resp.: KCl 0.966, 0.928, 0.902; CsNO₃ 0.966, 0.928, 0.902; K₂SO₄ 0.889, 0.781, 0.715; Ba(NO₃)₂ 0.889, 0.778, 0.710; MgSO₄ 0.765, 0.572, 0.471; CuSO₄ 0.762, 0.560, 0.444; La₂(SO₄)₃ 0.477, 0.232, 0.150.

D. S. VILLARS

Heterogeneous kinetics of dissolved gases. I. The elimination of carbon dioxide from an aqueous solution to a stream of bubbles of an indifferent gas streaming through

it. FRIEDRICH POLLAK. *Monatsh.* **45**, 539-68(1924).—An arrangement is described whereby the rate of elimination of CO_2 from an aq. soln. could be continuously detd. during the passage of a const. stream of N bubbles. On the basis of *Henry's law* an expression $dx/dt = K Bw(N - x)$ is derived for the rate of this elimination. B , is the no. of bubbles of surface area w passing through the soln. whose concn. is N , in unit time; K is a const. Lack of precision in the results prevented their exact interpretation.

ARTHUR GROLLMAN

Relative rates of certain ionic reactions. A. W. FRANCIS. *J. Am. Chem. Soc.* **48**, 655-72(1926); cf. *C. A.* **19**, 2814.—The relative rates of oxidation of several inorg. reducing agents by Br-water were estd. by making these reactions compete with certain irreversible org. substitution reactions. About 300 expts. are reported. To get gradual mixing a special app. was used which delivered the Br-water and the mixt. of competitors at equal slow rates into agitated distd. H_2O . The ratios between the rates of the inorg. and the org. reactions are nearly independent of temp. and concn. The reactivity of a solute is increased by a decrease in soly. and, like thermodynamic activity, is max. in satd. soln. This is a partial explanation of the effect of solvent on reaction velocity. The relative velocity consts. of oxidation (compared with K for TiCl_3 , which is about 10^7) are $\text{Na}_2\text{S}_2\text{O}_3$ 15, HI 14, NaHSO_3 8.6, SnCl_2 4.1, NaAsO_2 4.0, $\text{K}_4\text{Fe}(\text{CN})_6$ 2.4, TiCl_3 1.0, FeSO_4 0.3, FeCl_2 0.3, NaNO_2 0.003. A new volumetric analysis of H_3AsO_4 is given. $\text{Na}_2\text{S}_2\text{O}_3$ reacts faster than NaHSO_3 with I_2 (cf. Eggert, *C. A.* **19**, 766).

A. W. FRANCIS

The catalytic synthesis of water vapor in contact with metallic nickel. A. F. BENTON AND P. H. EMMETT. *J. Am. Chem. Soc.* **48**, 632-40(1926).—From a study of the combination of O_2 and H_2 in contact with reduced Ni and consideration of the work of other authors, it is concluded that the catalytic H_2O formation can be largely and perhaps entirely accounted for on the hypothesis of successive oxidation and reduction of the catalyst. Activation of H_2 does not play a prominent part in the reaction.

F. L. BROWNE

Composition and catalytic action of platinum electro-sols. A. DE GREGORIO ROCASOLANO. *Nachr. Ges. Wiss. Göttingen* **1924**, 177-88.—Because the addn. of protecting colloids such as gelatin increases the stability of Pt hydrosols made by elec. dispersion but decreases their effectiveness as catalysts for the decompn. of H_2O_2 , it is concluded that the chem. compn. of the Pt particles is the important factor governing catalytic action rather than phys. properties such as size of particles. Analysis of the gas evolved during prepn. of the Pt sols by elec. dispersion shows it to consist entirely of H_2 . When the coagulum from such sols is heated, O_2 is given off. The particles of colloidal Pt are therefore composed of Pt and an oxide. The particles are assumed to consist of cryst. masses of Pt torn off from the electrodes during prepn. enclosed in a layer of Pt oxide. The shell of oxide adsorbs OH^- from H_2O , giving the particles a negative charge. The catalytic effect on the decompn. of H_2O_2 is presumed to take place through the alternate reduction of the oxide shell to a lower oxide and its subsequent reoxidation. The catalytic power of a given Pt sol is measured by the amt. of O_2 taken up during its formation. In conformity with this conclusion it is found that (1) the catalytic activity is increased by increasing the proportion of O_2 bound (through control of the exptl. conditions during prepn.); (2) a coagulum from a Pt sol loses its activity when heated to redness and then suspended in H_2O again; (3) sols which have been treated with KI in acid soln., whereby I_2 is set free, lose their activity. The amt. of I_2 liberated by reaction with KI may be taken as a measure of the amt. of O_2 bound, although the results do not check with those obtained by direct detn. To account for this it is assumed that the Pt particles combine with O_2 in 2 different ways. The fact that the catalytic activity is not directly proportional to the amt. of O_2 bound indicates that phys. factors also play a part, even if a minor one.

F. L. BROWNE

Equilibrium between two liquid phases. II. Aniline-lactic acid-water. E. ANGELSCU. *Bul. soc. chim. România* **7**, 72-8(1925); cf. *C. A.* **19**, 3055.—The equil. between the 2 liquid phases of the system was studied by detg. the isotherms at 0° and 20° , the partition coeff. at 20° and variations in the equil. with the temp. The soly. curves of this system have an upper crit. soln. temp., which decreases rapidly with increase in the concn. of the mixt. in lactic acid. The difference between the general shapes of these curves and of those obtained with $\text{PhNH}_2\text{-AcOH-H}_2\text{O}$ is attributed to the greater strength of lactic acid, as compared with AcOH , resulting in less hydrolysis of PhNH_2 lactate. III. *o*-Toluidine-acetic acid-water. *Ibid* **79-90**.—The binary system *o*-toluidine- H_2O has an upper crit. soln. temp. of 216° with a concn. of about 50% *o*-toluidine. The ternary system *o*-toluidine- $\text{AcOH-H}_2\text{O}$ gives closed soly. curves

with upper and lower crit. soly. temps. With 24.52% AcOH in the mixt. the 3 constituents are miscible at all temps. and for all proportions of the other 2. A. P.-C.

The behavior of cyanamide in acid and alkaline solutions. G. GRUBE AND G. MORZ. *Z. physik. Chem.* 118, 145-60(1925); cf. *C. A.* 8, 876.—The equil. $2\text{CNNH}_2 \rightleftharpoons (\text{CNNH}_2)_2$ is investigated by the method given previously. In slightly alk. solns. and at low temps. the reaction goes practically entirely to the right. In strongly alk. solns. and at temps. above 50° , an equil. can be reached from both sides, which advances to the left with rising p_H . The basic dissocn. const. $(\text{CNNH}_2\text{OH}) \times (\text{H})/(\text{CNNH}_2 + \text{H}_2\text{O})$ is detd. at 25° by the sapon. of MeOAc to be 2.5×10^{-16} . The hydrolysis $\text{CNNH}_2 + \text{H}_2\text{O} \rightarrow \text{CO}(\text{NH}_2)_2$ is in dil. solns. a reaction of the first order and below $p_H = 1$ approx. proportional to the H-ion concn. Only when the soln. is concd. as to CNNH₂ and dil. as to acid, a reaction of the second order takes place, because some of the catalyzing acid is lost by salt formation with urea. JOHN T. STERN

Statistics of a diatomic gas and its heat capacity. K. N. SHAPOSHNIKOV. *Bull. Inst. Polytech. Ivanovo-Vosneisensk* 7, 132-42(1923).—S. discusses the observed phenomenon of increase in heat capacity of diat. gases with the increase in temp. He discusses the value $5 RT/2$, which according to the kinetic theory is the energy possessed by a g.-mol. of a diat. gas. He analyses the derivation of this formula by the Plank-Einstein function and through a series of calcns. arrives at the following formula for the total energy: $E = 3RT/2 + 2N(\epsilon/e\epsilon/kt - 1 + \epsilon/2)$. J. S. JOFFE

Measurement and production of high temperatures attaining that of the sun. M. PICON. *J. pharm. chim.* [8] 2, 285-98(1925).—An extended review, based on the work of O. Lummer (*C. A.* 9, 143, 2351) and the advances in pyrometry (cf. Weiss, *C. A.* 15, 2227). S. WALDBOTT

The thermal properties of viscous sulfur. P. MONDAIN-MONVAL. *Compt. rend.* 182, 58-60(1926).—Calorimetric expts. with viscous S, sealed in a glass bulb, have given the following values: Heat of transformation of liquid S into viscous S at about 160° , 2.8 ± 0.1 cal./g. (absorbed); sp. heat of orthorhombic S, 0.176; sp. heat of liquid S, 0.220, and of viscous S 0.290; heat of transformation of orthorhombic S into monoclinic at 95° , 2.7 cal. and the heat of fusion of monoclinic S 9.3 cal. A. W. KENNEY

Thermochemistry of beryllium. C. MATIGNON AND G. MARCHAL. *Bull. soc. chim.* 39, 167-90(1926).—See *C. A.* 20, 695. E. H.

Thermoelectric effect and the heat capacity of electrons in metals. E. D. EASTMAN. *J. Am. Chem. Soc.* 48, 552-62(1926).—The apparent heat capacity of electrons, that is to say the excess heat capacity of metal contg. free electrons over the Debye value, is not the same quantity as the partial molal heat capacity of electrons which occurs in the equation for the Thomsen effect. These two quantities may have different signs. The importance of the Soret effect in this connection is pointed out. F. R. BICHOWSKY

Specific heats of hydrocyanic acid. A reply. EDITH H. INGOLD. *J. Am. Chem. Soc.* 129, 26-9(1926).—A reply to criticism by Partington and Carroll (*C. A.* 19, 2160). F. R. BICHOWSKY

The thermal dissociation of sodium cyanide. E. W. GUERNSEY AND M. S. SHERMAN. *J. Am. Chem. Soc.* 48, 695-704(1925).—Pure NaCN can be prepared by pptn. of NaOH by excess HCN in EtOH. The pure NaCN is not stable at temps. of 600 – 1255° . In atm. of He or N₂, it reversibly dissociates into N₂, Na₂C₂, Na and C. At 1050° the partial pressures in mm. Hg are as follows: Na 117, Na₂C₂ 21.0, N₂ 108, NaCN 21. Equil. const. could not be calcd. with great accuracy because of exptl. conditions. F. R. B.

The free energy and heat of formation of iron carbide for the temperature interval 650 – 700° . H. L. MAXWELL AND ANSON HAYES. *J. Am. Chem. Soc.* 48, 584-93(1926).—Equil. const. for the reaction $3\text{Fe}(\alpha) + 2\text{CO} = \text{CO}_2 + \text{Fe}_3\text{C}$ were measured at 1 atm.; a flow method was used and resultant gases were analyzed. The vol. percent CO₂ at equil. was 35.7 ± 0.1 at 650° , 25.25 ± 0.05 at 700° . From data of Rhead and Wheeler for equil. const. of reaction $2\text{CO} = \text{C}(\text{graphite}) + \text{CO}_2$, ΔF for reaction $3\text{Fe}(\alpha) + \text{C} = \text{Fe}_3\text{C}$ is 3138 cal. at 650° and 2281 cal. at 700° . These data give ΔH at $675^\circ = 19,162$ cal. F. R. B.

Influence of elastic tension on the thermoelectrical force. ESTER MAJO. *Rend. accad. sci. Napoli* 29, 159-67(1923).—Tables of the slight but noticeable change of the Peltier effect under elastic deformation of various metals combined with Cu. JOHN T. STERN

The determination of transition points in non-aqueous solutions by the electromotive force method. R. B. MASON AND J. H. MATHEWS. *J. Phys. Chem.* 29, 1507-16(1925).—The e. m. f. method is used for detg. transition pts. of salts in solns. of anhyd.

C_6H_5N . The temp. e. m. f. curves for the cells, $Cu-Hg | CuCl_2 \text{ 2py.} || HgCl_2 \text{ 2py.} | Hg$, and $Cu-Hg | CuCl_2 \text{ 2py.} || CdCl_2 \text{ 2py.} | Cd-Hg$, show breaks at 55° which are evidently due to the transition, $CuCl_2 \text{ 2py.} \rightleftharpoons 3CuCl_2 \text{ 2py.}$ The temp.-cond. curve has a similar break at 56° . The cell, $Cd-Hg | CdCl_2 \text{ 2py.} | \text{satd. soln. } ZnCl_2 | ZnCl_2 \text{ 2py.} | Zn-Hg$ was very satisfactory as regards cond., stability and reproducibility. Sharp breaks in temp.-e. m. f. curves at 9.3° indicated $CdCl_2 \text{ 6py.} \rightleftharpoons CdCl_2 \text{ 2py.}$, which agrees with 9° obtained by the soly. method. The Cd and Pb amalgams change polarity irreversibly when the cell, $Pb-Hg | PbCl_2 \text{ 2py} | \text{satd. soln. } PbCl_2 | CdCl_2 \text{ 2py.} | Cd-Hg$ is heated. There are indications of a transition pt. at 53° . R. E. GIBSON

The electrolysis of acid solutions of copper sulfate. L. V. REDMAN. *J. Phys. Chem.* **29**, 1548-55(1925).—An account of work done in 1910 as a preliminary for further publications on the subject. Siegrist (*Z. anorg. Chem.* **26**, 273(1901)) noted that in the electrolysis of solns. of $CuSO_4$ in H_2SO_4 , when the ratio $[CuSO_4] / \text{current d.}$ falls below a certain value, the deposition of Cu is independent of the current. He assumed that the reaction is really one of chem. reduction and hence depends on $[CuSO_4]$. Rosebrugh and Miller (*C. A.* **5**, 1013) accounted for the phenomenon on the basis of velocity of diffusion at the electrode. R. shows from the results of unequivocal expts. with interrupted current electrolysis that the theory of R. and M. is to be preferred to that of S. Qual. expts. on the voltage-time curve during the first few seconds of an electrolysis also lend support to the diffusion theory. R. E. GIBSON

The problem of hydration. III. Electroendosmosis and electrical transport of water. HEINRICH REMY. *Z. physik. Chem.* **118**, 161-92(1926); cf. *C. A.* **9**, 1869. The transport of H_2O by electrolysis across a membrane may be due to stoichiometrical hydration, electrodynamical transport of solvent or endosmosis. The results of expts. reported upon (*C. A.* **17**, 3826) are presented in tables and curves. All diaphragms are previously tested for their porosity under a pressure of 150 cm. of water. Different diaphragms of the same material show a H_2O transport parallel to their porosity but this does not hold for different materials. In pure H_2O , S powder, clay and Zsigmondy-Bachmann membrane show a very high endosmotic effect. Animal charcoal, gelatin, and parchment paper show a low effect. The same division into 2 groups is found in KCl solns. from 0.001 N to 1 N . Progressing to concns. above 0.02 N , there is a rapid drop of the factor dv/F with the first 3 substances, which is characteristic for endosmosis. For theoretical reasons the *sp. electroendosmosis*, a term which is derived from the formulas of Helmholtz and Smoluchovsky, can only decrease with increasing concn. as far as the ionic adsorption in the membrane is concerned. The curves for *sp. cond.* $\times dv/F$ in relation to $\log 1/n$ show for most membranes (except parchment) with alkali cations an increase above $n = 0.02$. The alk. earths produce a similar decrease (gelatin membrane). JOHN T. STERN

Duplex electrodes of the second type. PHILIPP GROSS and OTTO HALPERN. *Z. physik. Chem.* **118**, 255-6(1925); cf. *C. A.* **19**, 1808, 2446.—Polemical. J. T. S.

Anomalies observed in the magnetism of gases. A. GLASER. *Ann. Physik* **78**, 641-58(1925).—A continuation of investigations, previously described, with improved app. (cf. *C. A.* **19**, 2295). Results for O_2 , CO_2 and CO are given both in detailed tables and graphically. W. W. STIFLER

Magnetic properties of the carbonyl radical. P. PASCAL. *Compt. rend.* **182**, 215-7(1926).—By taking the value of the susceptibility of the CO radical from measurements on aldehydes, values were computed for amides, acids, urea, carbamates, and carbonates which were in good agreement with exptl. results. P. concludes that the increase of diamagnetism produced by N is accentuated when it is replaced by a neg. radical, but is distinctly diminished upon substitution by a pos. radical. This explains the apparent anomalies observed in compds. with doubly bound O . W. W. S.

The optical behavior of alumina fibers. W. KRAUSSE. *Kolloidchem. Beihefte* **21**, 282-304(1926).—The double refraction of alumina fibers is a minimum after imbibition of liquids whose n is 1.53. The residual double refraction is pos. in the direction of growth of the fibers and is attributable either to the difference in dispersion between fiber and imbibed liquid or to the fiber itself. Cetyl alc., cholesterol, narceine, coumarin, *p*-cresol, paraffin and stearin form sub-microscopic crystals in the interstices of such fibers. They are oriented by the structure of the fibers so as to give a summation of refraction, which is pos. with coumarin and *p*-cresol and neg. with the others. Staining of the implanted cetyl alc. and narceine with I gave a *dichroism* which in the direction of growth of the fibers had the same character as that obtained along the long axis of the crystals of the pure substances. Fibers show dichroism when stained with methylene blue, Au , Ag or Hg , but not with Berlin blue. Staining with metals changes the double refraction, which becomes neg. in the direction of growth with Au and Ag . A. G.

The physical nature of the sun's corona. II. WILHELM ANDERSON. *Z. Physik* 34, 453-73(1925).—A. first discusses previous theories in regard to the sun's corona and finds them unsatisfactory. The distribution of a gas in the gravitational field of the sun is used to derive a relation between the temp. of the base of the corona (the upper surface of the chromosphere) and the radii of the base and outer surface of the corona. The temp. of the outer surface is taken as 0° abs. The temp. of the outer surface of the chromosphere is calcd. for different at. wts. of the gas of the corona and it is found that electron gas would have approx. the at. wt. necessary to give the correct temp. of the chromosphere. A. concludes that the corona is probably pure electron gas.

S. C. LIND
H. C. URREY

The origin of the penetrating radiation. MINESABURŌ AKIYAMA. *Japn. J. Astron. Geophysics* 3, 1-6(1925).—A. correlates data on the diurnal and seasonal variation of the penetrating radiation with auroral appearances and advances evidence supporting the assumption that the radiation is caused by the aurora. If auroral light is caused by bombardment of N₂ mols. by α -particles from the sun, this occasionally results in the release of radiation harder than ordinary γ -rays (cf. C. A. 19, 1812). Max. in frequency of auroral appearances as well as in amt. of penetrating radiation occur in the morning and evening and in the months April and Sept. (cf. C. A. 15, 464; 18, 2642; *Z. Physik* 11, 379; 21, 324; *Jahr. Rad. Elekt.* 14, 383). As aurora is apt to follow transit of sun spots and be accompanied by a magnetic storm, these do not cause the radiation but merely accompany it. (Cf. *Compt. rend.* 173, 722.)

D. S. VILLARS

Apparatus for measurement of penetrating radiation. WERNER KOLHÖRSTER. *Physik. Z.* 27, 62-3(1926).

Have radium rays an influence on the potential of the hydrogen electrode? M. TZENTNERSHVER AND M. STRAUMANIS. *Z. physik. Chem.* 118, 240-50(1925).—An attempt is made to calc. the degree of dissocn. of H₂ under normal conditions. For theoretical reasons the potential of a H₂ electrode should become more neg. by 8.4 milliv., if the concn. of at. H in Pt is doubled. Thirty mg. of RaBr₂ near a H₂ electrode fail to produce an effect detectable by an app. with a sensitivity of 10⁻⁶ v. The ionization of the H atm. is detd. by a condenser which is built into the electrode vessel. Expts are made with H₂ + N₂ and H₂ + SO₂.

JOHN T. STERN

Radioactivity and ionization measurements of air at Tuja-Moujoun (Fergana). V. I. BARANOV. *Bull. acad. sci. Russie* 19, 427-48(1925).—The methods for measuring radioactivity and ionization of air have to be independent of the air purity factor. The measurement of the intensity of ion formation may give a value of abs. significance to judge the activity of the given region. The radioactivity measurements of the air may give the general characteristics of a more or less wide area. Local conditions influence ionization more than radioactivity, especially where an exchange with soil air takes place. Caves could be studied for their Rn with the Schmidt app. Ionization of cave air gives no indication of their radioactivity. In the district of Tuja-Moujoun on account of the Ra deposits the radioactivity and ionization of air are increased.

J. S. JOFFE

Absorption of β -rays by matter. (MME.) J.-S. LATTÈS AND GEORGES FOURNIER. *Compt. rend.* 181, 1135-6(1926); cf. C. A. 20, 702.—The linear relation $\mu/\rho = a + bN$ holds for 3 groups of primary β -rays selected from the complex radiation of a tube of Ra accompanied by its disintegration products. The ratio a/b in all cases studied is const. and = 105. The form $\mu/\rho = b(105 + N)$ is, therefore, proposed for the absorption law.

NORRIS F. HALL

The chemical properties of mesothorium 2 and actinium. ELLEN GLEDITSCH AND C. CHAMIE. *Compt. rend.* 182, 380-1(1926).—Five different chem. tests prove that MsTh 2 belongs to the Ce group of rare earths and is especially like La. These results can also be applied to Act, its isotope.

MARIE FARNSWORTH

Uranium X—its extraction and estimation. RAJENDRALAL DE. *J. chim. phys.* 23, 197-204(1926).—See C. A. 20, 1027.

E. H.

Emission of cathode bundles under vacuum. R. MAGINI. *Nuovo cimento* [N. S.] 2, 485-510(1925).—The form of discharge from cathodes of various shapes and under various stages of vacuum was studied. In all the cathodes studied the deflection of the final rays increases on diminution of pressure and with the distances between opposed points in the cathode. In a cylindrical tube with the bases sufficiently close the cathode streams are normal to the base; the ions strike against the walls and there is no production of canal rays. The course of the cathode rays under various exptl. conditions is described and diagrammed in detail.

L. T. FAIRHALL

Kinetic theory of metallic conduction and the scattering of electrons by atoms. E. L. DAVIES AND G. H. LIVENES. *Proc. Cambridge Phil. Soc.* 22, 555-61(1925); *Science Abstracts* 28A, 565.—A mathematical paper. It is concluded that a purely kinetic theory is quite capable of explaining the phenomena of cond. in metals. H. G.

Laws governing the pulling of electrons out of metals by intense electrical fields. R. A. MILLIKAN AND C. F. EYRING. *Phys. Rev.* 27, 51-67(1926).—The electron current pulled from a W filament increases from 10^{-12} to 10^{-8} amp. as the field is increased from 400 to 1100 kv. per cm. In the dark, luminous spots were seen on the anode, indicating that these currents come from a few active surface spots. A study is made of the variation of current with temp. It is suggested that these currents are due to conduction electrons pulled from minute peaks on the surface. D. C. BARDWELL.

The distribution of energy between the modified and the unmodified rays in the Compton effect. Y. H. WOO. *Phys. Rev.* 27, 119-29(1926).—With small tubes of the Compton type and Soller collimators, reliable measurements of the intensity of scattered X-rays were obtained from five radiators: paraffin, wood, C (graphite), Al and S. The increase in the ratio of the modified to the unmodified line with the angle of scattering agrees in general with Jauncey's theory, but the numerical values given by the theory are 20 to 50% too large. The results are discussed in detail. D. C. B.

Low-voltage discharges in helium. W. H. MCCURDY AND P. DALTON. *Phys. Rev.* 27, 163-72(1926).—Measurements of potential distribution, of mean energy and of concn. of electrons were made in the He discharge at pressures from 0.01 to 2.9 mm. The electron concn. is a max. in the negative glow and falls off to a min. near the cathode side of the first striation. D. C. BARDWELL.

The character of the ionization produced by spraying water. P. J. NOLAN. *Phil. Mag.* [7] 1, 417-28(1926).—The object of the investigation was to det. whether the ions produced by spraying water have mobilities varying continuously over a wide range or whether they are concd. in certain groups or bands. The Zeleny method of measuring mobility was used on account of its high resolving power. A no. of current-voltage curves are shown; the breaks indicate that the water-spray ions preferentially take certain sizes, although these are distributed all the way from "small" ions up to the Langevin "large" ions. Whether these groups include these ions only or whether in addn. there is a general back ground of ions of all sizes the expts. were not crit. enough to det. The proofs of low mobilities 0.00033, 0.0012 and 0.0041 cm./sec./volt/cm. were found in every case. S. C. LIND.

The equilibrium of ionization in the atmosphere. J. J. NOLAN, R. K. BOYLAN AND G. P. DE SACHY. *Proc. Roy. Irish Acad.* 37, 1-12(April, 1925); *Science Abstracts* 28A, 561.—Some results are presented from a general investigation of atm. ionization, nucleation and kindred phenomena. It is found that: (1) The large ions in the atm. carry single electronic charges. (2) A const. fraction of the nuclei of the atm. is charged, i. e., is large ions. The ratio of the uncharged nuclei to the large ions of one sign is 1.28 approx. (3) The equil. between large and small ions in the atm. is detd. by the equation $q = \alpha n^2 + 2\eta_2 N n$, where α is the ordinary recombination coeff. for small ions and η_2 is the recombination coeff. between small and large ions of the opposite sign. When large ions are plentiful the relation is $q = 2\eta_2 N n$. The value of η_2 is 9.7×10^{-6} . (4) A close relation exists between the atm. potential gradient and the concn. of nuclei (and therefore of large ions) in the air. Exptl. details with data and curves are included. H. G.

Gas flow and pressure changes in gases under electric discharge. R. G. LUNNON. *Phil. Mag.* [7] 1, 482-91(1926).—Measurements have been made of the mol. and viscous flow of gases in fine capillary tubes at low pressures. The rate of flow is unaffected, to within less than 5%, by an elec. discharge passing through the flowing gas. A theoretical discussion suggests that an effect is to be expected with diatomic gases at very low pressures. Observations have been made of the disappearance and emission of gas in discharge tubes. The change of pressure follows an exponential law when it occurs, and under special circumstances there may be no change. The gases used in the flow expts. were pure N_2 , commercial O_2 , air and a mixt. of 75% A, 25% N_2 and a trace of O_2 . S. C. LIND.

The so-called positive photoelectric emission (inverse effect) and the reality of the subelectron. E. J. LORENZ. *Phil. Mag.* [7] 1, 499-509(1926).—The inverse photoelec. effect is a spurious effect, and is not due to discharge of positive electricity. This has been proved by careful work on oil, glycerol and Hg drops in various gases. Work with Hg drops shows that the drops that yield values of " e " smaller than 4.77×10^{-10} e. s. u. also show an abnormal behavior to ultra-violet light, that is, they are only slightly sensitive or not sensitive at all. The multiple relationship holds for the charges on

these insensitive drops, proving that their charges are electronic, and that it is erroneous to assume their density to be that of Hg. Drops that are known to be pure Hg satisfy Millikan's $e_1^{1/2}$, $1/pa$ relation, and yield 4.77×10^{-10} e. s. u. for the electronic charge, and 0.695 as the value of the correction const., A , in Stokes' law. S. C. LIND

X-ray radiation from hot sparks. ALBERT BJÖRKESON. *Proc. Nat. Acad. Sci.* 11, 413-5(1925).—A vacuum spectrograph of the Siegbahn type was used with Ag, Al, Si, S and Cu as electrodes and a gypsum crystal as a grating. The plates showed all the earlier known characteristic lines in the L-series spectrum of Ag, and the K-series for the other elements including the so-called spark-lines. No new lines nor any shift nor broadening of the old ones was observed. From the plates the conclusion is drawn that the multiple ionization giving rise to the enhanced X-ray lines of the K-series must be due to simultaneous ejection by a single impact. J. F. SCHAIERER

Significance of the discovery of X-ray laws in the field of optics. R. A. MILLIKAN AND I. S. BOWEN. *Proc. Nat. Acad. Sci.* 11, 119-22(1925); *Science Abstracts* 28A, 459.—Series of atoms of elements from Na to Cl and Li to N have been obtained without valence electrons (cf. C. A. 18, 3537). The working out of the corresponding energy levels has shown that the Moseley and irregular doublet laws hold with optical spectra as well as with X-ray spectra. The same seems to hold also for the regular or relativistic doublet law. As this would involve the abandonment of either relativity causes and effects or of Bohr's interpenetration ideas, the data have been again examined. It is concluded from small discrepancies in values of the screening const., that only the doublets of H and He really obey the law, and that those for other elements are not really relativistic doublets, although they very nearly obey the same law. H. G.

The resonance absorption of X-rays. M. V. POSEJAL. *Compt. rend.* 182, 272-4(1926).—It appears from previous investigations that the secondary radiation produced by the photoelec. effect of X-rays does not follow Einstein's law, the emitted amt. of electronic energy being larger and that of electromagnetic energy smaller than calcd. The agreement between theory and expt. may, however, be established by the assumption of a resonance absorption in the first series of the X-ray spectrum. The absorption of the K-series of W by a sheet of the same metal was observed by means of a Seemann spectrograph. While the absorption of the line β_1 is a normal one the absorption values of α_2 and α_1 , were higher than calcd. This phenomenon of an obviously selective absorption is attributed to a resonance absorption taking place in connection with the ionization or excitation of the atom and depending on the no. of electrons in the spheres L_2 and L_1 . ÉMIL KLARMAN

The excitation of soft X-rays. O. W. RICHARDSON AND F. C. CHALKLIN. *Proc. Roy. Soc. (London)* 110A, 247-82(1926).—Soft X-rays have been excited at 40-600 Å from C, Ni, Fe and W, and studied by a photoelec. method. The breaks on the curves between efficiency of X-ray emission and primary voltage correspond to the following voltages: C: 39.5, 81.2, 265.0, 292.8; W: 36.8, 40.3, 44.9, 70.8, 108.2, 127.7, 150.0, 191.0, 245.2, 263.7, 336.0, 395.0, 419.0; Ni: 38.6, 80.0, 88.9, 99.0, 140.3, 245.5, 282.0, 288.0, 316.4, 335.0, 392.4, 433.0, 532.0; Fe: 45.6, 50.6, 63.7, 75.6, 84.8, 95.0, 107.6, 115.1, 137.6, 189.7, 221.5, 240.6, 270.2, 288.3, 498.0. Most of these discontinuities are due to excitation of characteristic radiation, but some are probably due to discontinuities in the general X-radiation, arising from the space distribution of the electrons in atoms. The total X-radiation per electron impact is approx. proportional to the square root of the at. no. of the target element. R. J. HAVIGHURST

The relative intensities of reflection of X-rays from the principal atomic planes of fluorite. D. A. MACINNES AND THEODORE SHEDLOVSKY. *Phys. Rev.* 27, 130-7(1926); cf. C. A. 19, 1817.—The method of Bragg is modified by adding a reference crystal illuminated through the same slit on a line slightly above the other, and a second ionization chamber and Bumstead electroscopes. D. C. BARDWELL

K-series emission spectra for the elements from tantalum to bismuth. B. R. STEPHENSON AND J. M. CORK. *Phys. Rev.* 27, 138-43(1926).—Accurate measurements were made of the K-lines for all elements from Ta to Bi, excepting Hg, the elements being placed in sheets or layers on a thin Cu target. The $\sqrt{\nu/R}$ values plotted against at. no. give practically a straight line, where ν is the frequency and R is Rydberg's const. D. C. BARDWELL

The X-ray spectra of the lower elements. ROBERT THORAEUS. *Phil. Mag.* 41, 1, 312-21(1926).—By using a vacuum spectrograph and reflecting crystals of palmitic and lauric acids the spectra of some of the lighter elements have been extended into the K and L series. New wave-length values are given for F in the K-series and for Rb, Br, Se, As, Zn, Cu, Ni, Co, Fe, Mn and Cr in various members of the L-series. S. C. LIND

The excitation potentials of the band spectra of nitrogen. H. SPONER. *Z. Physik* **34**, 622-33(1925).—The energy diagram for neutral N_2 is derived from data in the literature together with new data on the critical potentials required to excite the positive and negative bands. The second positive bands appear at 13.0 v. and the excitation potentials of the first and fourth positive bands are calcd. to be 9.3 and 14.8 v., resp., from spectroscopic data. The excitation of the negative bands requires 19.6 v. and the ionization of the mol. is then calcd. to be 16.5 v. The origin of the active N and the afterglow is discussed. It is suggested that the active N is at N and that the afterglow is due to light emitted as the atoms recombine. The trace of O_2 necessary to secure the afterglow may act as a poison to the glass walls just as water does in the case of the monatomic H.

H. C. UREY

Intensity measurements of the iron spectrum. I. J. B. VAN MILAAN. *Z. Physik* **34**, 219-23(1925).—The intensities of the $f'_1 - d'_1$ multiplet of iron are measured. The summation rule of Burger and Dorgelo is obeyed for low current in the arc. The intensity formula of Honl, Kronig, Russell and Sommerfeld is not obeyed. H. C. U.

Additions to the series of the lead arc spectrum. H. GIESLER and W. GROTRIAN. *Z. Physik* **34**, 373-88(1925).—The arc spectrum of Pb has been studied in a heated vacuum discharge tube. This was tried with Tl first and some 15 new lines of the subordinate series are recorded. The known series of Pb consisting of transitions between the p_1, p_2, p_3 and P_2 levels and the ms, md_1, md_2 and md_3 levels are extended. New series consisting of transitions between the p_2 and P_2 levels and the mf_3 levels and between the P_0 level and the ms and md_1 levels have been found. A number of unclassified lines are also recorded.

H. C. UREY

Measurements of the intensity of the lines of the many-lined spectrum of hydrogen at different temperatures and pressures. F. GOOS. *Z. Physik* **31**, 229-39(1925); *Science Abstracts* **28A**, 453-4.—A photographic photometric arrangement is fully described, by means of which the relative intensities of the Fulcher triplets and some other lines in the red part of the many-lined spectrum of H are investigated for 3 different temps. and 4 different ds. of the gas, also for 12 different conditions. The results are given in both tabular and graphical form. It is found that, relative to a standard line, a part of the lines are sensitive to temp. as well as pressure, while of the others some are sensitive to d. only and the remainder to temp. only.

H. G.

The critical potential of the K band of neon. F. HOLWECK. *Compt. rend.* **182**, 53-4(1926).—Measurements of the exciting potential of the K-series of Ne gave a value of 862 v.

C. C. KIESS

The ultra-violet absorption spectra of aqueous solutions of sulfur dioxide and some of its derivatives. F. H. GETMAN. *J. Phys. Chem.* **30**, 266-76(1926).—The extinction coeffs. of aq. solns. of SO_2 and some of its derivs. were observed spectrophotometrically. The characteristic absorption band of SO_2 lies at 276μ . Curves illustrating the absorptions of $SO_2, Na_2SO_3, NaHSO_3$ and $K_2S_2O_8$ in H_2O are given. Solns. of $NaHSO_3$ are stable in light provided O or air is absent; but in the presence of these gases, photo-oxidation ensues, and the absorption band of the soln. changes to that of SO_2 . $K_2S_2O_8$ rapidly decomposes in soln., its characteristic absorption band at 263μ disappearing and that of SO_2 appearing. The frequency relationship of Baly connecting the ultra-violet bands with a fundamental infra-red frequency is applicable to the bands 263μ and 276μ .

C. C. KIESS

The line absorption spectra of the alkali metals. A. L. M. SOWERBY and S. BARRATT. *Proc. Roy. Soc. (London)* **110A**, 190-7(1926).—The lines $1s - md$ which, in the absence of an external field, are forbidden by the selection principle have been observed in absorption for the vapors of all the alkali metals. For Cs they are here observed for the first time either as absorption or emission lines and their wave lengths are found to be, $1s - 3d$: 6894.7 and 6848.5 A. U.; $1s - 4d$: 4425.8 and 4417.7 A. U. These values are only approx., but they indicate that the Cs term values are somewhat in error. Comparison of the absorption intensities of $1s - mp$ and $1s - md$ for K and Rb indicates that the probability for the absorption of $1s - mp$ is about 12,000 times that for $1s - md$. The line $1s - 3d$ of K was observed in emission in an intense flame, but could not be detected in a similar test with Na.

C. C. KIESS

The Doppler effect in canal rays of hydrogen, oxygen and nitrogen. H. KREFFT. *Sci. Assoc. Maharajah's Coll.* **2**, 21-40(1925).—See *C. A.* **18**, 3546; **19**, 931. C. C. K.

The interpretation of the spectra emitted by solid nitrogen and by solidified mixtures of nitrogen with inert gases. L. VEGARD. *Compt. rend.* **182**, 211-3(1926).—Several series of bands of simple structure are emitted by solid N when it is bombarded by canal rays or by rapid cathode rays. The series are the same whether the solid N

is pure or mixed with A. The series are all expressible by Deslandres' formula and are regarded as characteristic for Cr^{+} . C. C. KIESS

Displaced series in the spectrum of chromium. C. C. KIESS AND O. LAPORTE. *Science* 63, 234-6(1926).—Analysis of the arc and spark spectra of Cr has yielded sequences of ^1S , ^3S and ^3D terms which, according to Hund's theory (C. A. 20, 18) should converge, resp., to ^4S and ^4D of Cr^{+} . Of these terms, only ^4D was known; but from the series relationships ^4S should lie 12,730 cm^{-1} below it and should combine with ^4P to give a strong triplet of lines in the ultra-violet. A spectrogram of the region showed the triplet in its predicted place with wave lengths 2055.5 A. U., 2060.5 A. U. and 2065.4 A. U. A table describing the normal states of the neutral, ionized and doubly ionized atoms of the first and second long periods is given. C. C. KIESS

Spectrographic investigations of the Compton effect. M. DE BROGLIE AND A. DAUVILLIER. *J. phys. radium* 6, 369-75(1925).—Results confirming the Compton effect (C. A. 18, 2839) are given, following a description of the theory and the app. employed in the expts. C. C. KIESS

Infra-red absorption of the nitrogen-hydrogen bond. E. O. SALANT. *Proc. Nat. Acad. Sci.* 12, 74-80(1926).—Observations were made of the absorption of a series of symmetrical dialkyl- and trialkylamines. The dialkyl compds. have bands from 2.9 to 3.1 μ due to the N-H bond. Of the trialkyl compds. the aliphatic amines have bands from 3.45 to 3.52 μ due to the C-H bond, and the phenylamines and benzylamines show additional bands at 3.2 μ and 3.3 μ , resp. C. C. KIESS

The spectrum of neon in the extreme ultra-violet. T. LYMAN AND F. A. SAUNDERS. *Proc. Nat. Acad. Sci.* 12, 92-6(1926).—In the arc spectrum of Ne 16 lines were photographed with a vacuum grating spectrograph between the limiting wave lengths 743.7 A. U. and 586.4 A. U. in the extreme ultra-violet. All of these lines are assigned to their proper series and are found to be combinations between a low term $1p = 173,930$ and higher s and d terms found by Paschen (C. A. 15, 341). C. C. KIESS

The secondary spectrum of hydrogen at higher pressures. II. IAN SANDEMAN. *Proc. Roy. Soc. (London)* 110A, 326-41(1926); cf. C. A. 20, 15.—The arc spectrum of H_2 , excited at high pressures (C. A. 20, 15), has been studied further, with the result that additional band series have been found. Of these bands the most intense contains a series already given by Richardson and Tanaka (C. A. 19, 1988). The null lines of this band and three others, details for which are tabulated, are represented accurately by a Rydberg formula in which the current no. $n = 6, 7, 8, 9$. With this formula some lines of the Q and R branches of the band for which $n = 10$ have been found. C. C. KIESS

The absorption spectra of the vapors of aluminum, gallium, indium and thallium. J. G. FRAYNE AND ALPHEUS W. SMITH. *Phys. Rev.* 27, 23-30(1926).—The metals were vaporized in a graphite tube heated with an oxy-acetylene torch to temps. as high as 2000°. A W under-water-cooled spark provided a continuous emission spectrum. D. C. BARDWELL

The optical properties of chromatic emulsions. C. M. SOGANI. *Phil. Mag.* [7] 1, 321-33(1926).—The range of wave lengths transmitted by non-homogeneous emulsions is narrow and dependent upon the intensity of the incident light, the thickness of emulsion, the av. particle size, concn. of the disperse phase, and the difference in dispersion form of the two phases. The homogeneous emulsions contg. particles of uniform size are obtained by sedimentation. The light scattered by this does not give a continuous halo but is concd. in sharp diffraction rings. The surface sepg. the sedimented emulsion from the clear liquid above shows sparkling colors on both sides. A spectroscopic study showed this to be due to total reflection, the emulsion as a whole possessing a different dispersive power from that of the liquid. S. C. LIND

The production of some spectra of carbon, oxygen, and nitrogen in the presence of neon. W. H. B. CAMERON. *Phil. Mag.* [7] 1, 405-17(1926).—The effect of the presence of excess of the inert gas He, Ne or A in the various types of spectra of the gases contg. C, N or O produced by elec. discharge is demonstrated and discussed. The effects are strongest for He, weaker for Ne and weakest or absent for A. The various types of discharge dealt with are: comet-tail bands, associated bands, negative C bands, C arc lines, negative N bands, N arc lines, triplet system, ultra-violet O bands, negative O bands, O_1 and O_{II} . The possible causes of the various phenomena are discussed at length. S. C. LIND

The water-spark absorption spectrum of iron. N. K. SUR. *Phil. Mag.* [7] 1, 433-50(1926).—The paper describes exptl. work on the absorption spectrum of Fe, which is obtained when the high-frequency spark produced between two Fe electrodes immersed in distd. water is analyzed by a spectroscope. The exact exptl. conditions

are described in detail, and the results obtained are compared with the recent work of Laporte on the classification of Fe lines. All multiplets having the three highest groups of terms, viz. d^1 , f^1 and occasionally F^1 , as initial orbits, are obtained in absorption. Some weak lines are also obtained in absorption, which are shown to correspond to the transition of the azimuthal quantum no. from k to $k \pm 2$ (violation of Sommerfeld's selection-principle). This method of obtaining absorption spectra is as suitable as the more elaborate method of obtaining it in the furnace. Arguments are advanced in support of the view that Fe may have a term higher than the d -term, which is the highest so far obtained.

S. C. LIND

The absorption spectra of aluminum and cobalt. N. K. SUR AND K. MAJUMDAR. *Phil. Mag.* [7] 1, 451-62(1926).—The paper contains an account of exptl. work on the absorption spectra of Al and Co in the high-temp. furnace. The $2p_1 - 2s$, $2p_2 - 2s$ lines of Al do not come in absorption before a temp. of 1520° is reached. The higher members of ps - and pd -series are obtained in absorption at about 1700° . The absorption spectrum of Co has been photographed from 4500 A. U. to 3000 A. U. at a temp. of 2000° . The lines have been identified by measurement, and tabulated according to the series classification of Catalan and Bechert. It is shown that many lines belonging to f^1 and f^2 , and a few lines belonging to F^1 terms, which are the three successive largest terms, have been obtained in absorption. Only one line, 4190.709, belonging to the group which Catalan and Bechert have suggested for the resonance lines has come out in absorption.

S. C. LIND

Variations in the ozone content of the higher regions of the atmosphere. H. BUISSON AND C. JAUSSEAN. *Compt. rend.* 182, 232-4(1926).—Fabry and B. have shown (*J. phys.* [6] 2, 197(1921)) that the limitation of the solar spectrum in the ultra-violet region must be due to absorption by O_3 in this region of the spectrum, and that the quantity of O_3 present was equiv. to a thickness of 0.30 cm. of pure O_3 at normal pressure. The av. value of 0.30 cm. has been confirmed, and variations of 0.45 mm. were observed between extreme values measured once daily for over 2 months. These variations could not be related in any manner to variations in atm. conditions. A. P.-C.

The decomposition of potassium ferrocyanide in the light. G. ROSSI AND C. BOCCHI. *Gazz. chim. ital.* 55, 876-83(1925).—The earlier knowledge of this decompn. is reviewed. Baudisch and Bass (*C. A.* 16, 4137) found that N_2 solns. of $K_4Fe(CN)_6$ free from air in sealed tubes exposed to the light undergo a reversible color change. It is nearly indefinitely reversible and only after some months is some $Fe(OH)_2$ pptd. and this decompn. is interpreted by B. and B. R. and B. have studied this process in some detail. The decompn. of $K_4Fe(CN)_6$ in aq. soln. reaches an equil. that does not change in a short time. After 30 min. of exposure the max. amt. of KOH is formed in a N soln. The abs. amt. of KOH increases with the increase of the $K_4Fe(CN)_6$ concn. to a certain limit and then tends to decrease. The relative amt. of KOH present first diminishes, then increases and then diminishes again. The presence of KOH in a soln. of $K_4Fe(CN)_6$ favors the decompn. of the salt by means of light and this favorable action reaches a max. When the concn. is increased beyond this limit the favorable action tends to disappear. The reaction is at first perfectly reversible and then reaches a stage when it does not reverse completely in the dark and this tendency increases with the no. of exposures. The quantity of KOH formed increases with the no. of exposures. Fluorescent compds. do not catalyze this reaction. Heat cannot be used instead of light. If the temp. is high and if the duration of the exposure is many hrs. a decompn. of $K_4Fe(CN)_6$ takes place that is different from that due to light. The temp. in the light expts. did not exceed 45° . The latter results clearly indicate that the effect studied was not due to heat arising from the lamp used for illumination.

E. J. WITZEMANN

The variation of the electromotive force of a photoactive cell, containing a fluorescent electrolyte, when the amount of fluorescent material in solution is varied. WM. RILEY. *Phil. Mag.* [7] 1, 532-41(1926).—The photoactive cell consisted of a glass tube 2×20 cm. with a flat Pt spiral electrode at the lower end and a Pt wire at the upper. The electrolyte was in all cases 0.5 g. NaOH in 100 g. H_2O . No e. m. f. was set up by illuminating one electrode when no fluorescent substance was in soln. The concn. of fluorescein was then varied from 1.6 to 5000 mg. per l. The voltage was detd. with a Dolezalek electrometer, the readings of which were measured at successive time intervals. For all concns. the voltage increases rapidly with time. For the diluter soln. the max. voltage attained increases rapidly with concn. of fluorescein up to about 300-400 mg. per l. and then falls off slowly with further increase of concn. Similar results were obtained with eosin in glycerol and water between the limit of 3 to 30,000 mg eosin per l. That the e. m. f. should vary proportionally to the concn. for the lower

ranges is to be expected. The diminution of e. m. f. at the high concns. is discussed from the standpoint of Perrin's "protection" theory (*C. A.* **18**, 2648). S. C. LIND

4—ELECTROCHEMISTRY

COLIN G. FINK

The installation, operating characteristics and economy of Nathusius furnaces. E. BLAU. *Chem.-Ztg.* **50**, 6-7, 26-7 (1926).—B. describes the Nathusius furnace (cf. *C. A.* **6**, 1401, 2207) with the aid of several figures, also the layout of the transformer room and the regulating room, and the scheme for raising and lowering the electrodes. The electrode holders are "free-hanging," there being 3 top and 3 bottom electrodes. An installation consisting of 2 furnaces on a turntable and provided with a single set of electrodes and control equipment is also described. A. D. SPILLMAN

Economic operation of electric furnaces. R. S. KERNS. *Blast Furnace & Steel Plant* **14**, 133-5 (1926).—K. discusses economic operation of the elec. furnace in the acid steel melting practice. Curves showing the relative costs of steel produced in furnaces rated at 500, 1000, 2000, 3000 and 6000 lb. capacity when pouring from 1 to 8 heats per day for 25 days per month are reproduced. The figures used for plotting the curves were based on the averages of 5 standard sizes of well-known furnaces, 3 phase, automatically controlled, made in the U. S. A simple method of arriving at the cost of labor, power, and material per ton when pouring 1 or 8 heats per day is explained. A. D. S.

Electric power for chemical plants. J. L. McK. YARDLEY. *Elec. J.* **23**, 113-24 (1926).—Chem. plants require large quantities of cheap power, or large quantities of steam. Com. processes are classified as to one or the other. Operations in each class are analyzed and individual applications of elec. power are indicated. D. c. and a. c. generation are compared. Points discussed include: the efficiency of a turbogenerator unit, the effect of plant load conditions upon efficiency, the most efficient a. c. generating equipment, large electrochem. plant developments in 1925, methods of detg. efficiency of power-conversion equipment, a classification of efficiency losses, and Hg-arc rectifiers for electrolytic service. W. H. BOYNTON

Present status of the electrochemical and electrometallurgical industries. ROBERT FLUSIN. *Industrie chimique* **12**, 345-8, 393-7, 489-92, 537-40 (1925).—Review of progress during the last few years. A. PAPINEAU-COUTURE

The problem of organizing the aluminum industry in Russia. A. P. KOORDUMOV. *Trans. Inst. Econ. Mineralogy and Petrography* (Moscow) **1923**, No. 6, 1-80.—K. discusses the world's Al production, the Russian requirements and resources, the technical methods and reactions involved starting with (1) bauxite, and (2) clay. Economics of chlorine. D. A. PRITCHARD. *Trans. Am. Electrochem. Soc.* **49**, (preprint) (1926).—A brief chronological sketch of the economics of the Cl industry with its by-products. C. J. BROCKMAN

Chlorine in Japan. SHUICHIRO OCHI. *Trans. Am. Electrochem. Soc.* **49** (preprint) (1926).—The industry is reviewed from the date of its inception to the present. About 40,000 tons of bleaching powder and 25,000 tons of caustic soda per year are manufactured in Japan today. The bleaching powder is all of electrolytic Cl origin; 80% of the caustic soda produced today is electrolytic. C. G. F.

The electrolytic separation of carbon-bearing iron from its complex compounds with carboxylic acids. HEINZ SCHMIDT. *Z. Elektrochem.* **32**, 33-41 (1926).—The separation of C together with Fe from citrate, tartrate, succinate, oxalate, formate, acetate and carbonate solns. is shown to be a simultaneous process and its dependence upon the

cathode potential or the cathodic total current d. and upon the current efficiency for the deposition of the Fe is established. The latter fact is explained by a soln. and pptn. theory which also explains the carbonization of the Fe cathode in the Fe-free solns. The C in the Fe is formed principally from easily decomposable C-contg. gases. No reduction or pptn. of unknown ions (as ionized C) could be detected either by decompn. potential studies or by chem. analyses of the cathode soln. after an electrolysis of long duration.

J. H. PERRY

A simple method for measuring polarization and resistivity. H. E. HARING. *Trans. Am. Electrochem. Soc.* **49** (preprint) (1926).—A simple method for measuring polarization uses the static potential of the metal in the given soln. as the basis of reference. A glass tube with a capillary extension is filled with the same soln. as that undergoing electrolysis. A rod of the metal dips into this tube. The e. m. f. of the cell consisting of the unpolarized metal rod and the electrode under study is equal to the polarization of the latter. The errors due to contact potentials are avoided and the accuracies of the instrument approach that of the elaborate conventional methods. The new method is reliable in Cu-, Ni- and Ag-plating and appears generally applicable in electro-deposition. In these baths the polarization at both anode and cathode for several c. ds. was measured with (a) a calomel half-cell and potentiometer, (b) with the gauzes and potentiometer; and (c) with the gauzes and a voltmeter. Polarization results by (b) and (c) were practically coincident and in fairly close agreement with the half-cell. The possible application of the app. and principle here set forth in pedagogy, research and industrial control is indicated. A new method for the graphic analysis of the voltage used in electrolysis is described.

W. H. BOYNTON

The electrolytic preparation and some properties of metallic yttrium. A. P. THOMPSON, W. B. HOLTON AND H. C. KREMERS. *Trans. Am. Electrochem. Soc.* **49**, (preprint) (1926).—Metallic Yt was produced (after reduction with Na and with C, and the electrolysis of Yt_2O_3 in cryolite had failed) by electrolysis of fused $YtCl_3$ with small quantities of NaCl. Considerable quantities of cryst. Yt powder and 4 g. of coherent metal were obtained. Phys. and chem. properties of the metal are given. The metal is not pyrophoric and its alloys with Fe are brittle and resistant to acids.

W. H. BOYNTON

Charging storage batteries from direct current mains. L. S. LOOMIE. *Elec. World* **87**, 611(1926).—With low-voltage batteries, the simplest method to avoid trouble during the charging period of storage batteries is to disconnect the battery. But the detn. of the grounded side of a circuit is simple by means of either a voltmeter or a test lamp, and the precaution of connecting the proper terminal of a storage battery to the ground will avoid the burning out of the low voltage app., also shocks to operators. The location of charging resistances with respect to supply wires is illus.

W. H. B.

Cadmium in the electrical industry. N. F. BUDGEN. *Electrician* **94**, 271, 276 (1925); *Science Abstracts* **28B**, 336.—Several interesting applications of Cd in the elec. industry are outlined, the importance of which will increase as the cost of Cd is reduced. Edison's Cd/Cu oxide cell fell into disfavor when the Fe/Ni oxide cell was invented. Forseke and Aschenbach have recently described a new process for making spongy Cd plates to be used against Ni electrodes in a soln. of NaOH or KOH. The cost of such cells is about 3 times that of Pb cells of equal amp. hr. capacity. Cd is used together with finely divided Fe in the negative plates of accumulators for miner's lamps, etc., the Cd forms from 50 to 75% of the filling of the negative plates. Reference is made to the use of Hg-Cd alloys in standard cells and to the use of Cd rods in testing separately the conditions of the positive and negative plates in accumulators. Cd oxide finely ground with water, made into a paste, with or without addn. of Zr silicate, and then baked at 800°, can be used in the form of rods, tubes, etc., as a resistor material for elec. furnaces. Other applications are mentioned, and it is pointed out that probably one of the most important elec. uses for Cd will be in the manuf. of conductors for telegraph, telephone and power transmission lines.

Collector for separating finely divided charged particles suspended in gases. W. H. DICKERSON and W. B. McLAUGHLIN. U. S. 1,573,376, Feb. 16. The app. is adapted for sepg. solids in spray-drying.

Chromium-coated wires as electric apparatus leading-in connections. D. S. GUSTIN. U. S. 1,576,436, March 9.

Electric apparatus for automatically controlling acidity of solutions. F. H. OLDEN. U. S. 1,576,001, March 9.

Electric resistance furnace. F. J. PETERSON. U. S. 1,574,108, Feb. 23. A U-shaped groove in the resistor is adapted to hold a piece of stock to be heated.

Electric resistance furnace. E. L. SMALLEY. U. S. reissue 16,269, Feb. 16. Original pat. No. 1,459,801; C. A. 17, 2838.

Oxide terminal for resistors of electric furnaces. A. D. KEENE. U. S. 1,575,117, March 2.

Electric condenser. W. P. DAVEY. U. S. 1,576,096, March 9. Layers of conducting material are spaced apart with paper or similar material impregnated with linseed oil or like substance contg. a compd. of unsatd. fatty acids.

Protective coating for magnesium. L. J. KEELER. U. S. 1,574,289, Feb. 23. Mg or its alloys are brought into contact with nascent F which may be generated from a fluoride electrolytically in order to prevent tarnishing. U. S. 1,574,290 specifies electrolyzing Mg or its alloys as anode in a soln. of $\text{Na}_2\text{Cr}_2\text{O}_7$ or other alkali metal chromate.

Cooling electrodes of ozonizers. R. GRAEF. U. S. 1,575,049, March 2. Cooling air is passed in 2 independently regulable streams along internal and external electrodes.

5—PHOTOGRAPHY

C. E. K. MEES

Photochemical studies. VI. Mechanical effects on the photographic plate. A. REYCHLER. *Bull. soc. chim. Belg.* 34, 293-5(1925); cf. C. A. 20, 545.—Various different phenomena may be observed by writing on a photographic emulsion with a blunt metal stylus, depending on whether the plate be developed without exposure to light, exposed to diffuse light before or after the moment of writing thereon, etc. These phenomena are discussed and explained.

Professor Kögel's integral photography. A. STEIGMANN. *Camera (Luzern)* 4, 130-3(1925).—Integral photography is based upon the fact that certain substances behave like quinone diazides, which are decompd. by light to hydroquinol or *p*-aminophenol, which in turn, couple with undecomposed quinone diazide to give azo dyes in the presence of alkalis or NH_3 vapor. In its present form, integral photography cannot hope to approach the speed of Ag halide emulsions, since in integral photography there must be sufficient light action to produce the image-forming material of itself, whereas, in photography with Ag halide emulsions, the initial action of the light is amplified by the developing agent, and made to spread from mol. to mol. of the Ag halide. Kögel and Steigmann [*Phot. Ind.* 23, 1141(1925)] have been able to develop latent quinone diazide and dye images and to show the high sensitiveness of these substances.

M. W. SEYMOUR

Reduction of negatives. R. NAMIAS. *Photo-Revue* 5, 39-40(1926); cf. C. A. 19, 2787.—The recommended process consists in bleaching the upper layers of the image to AgBr, removing the lower layers of Ag with a soln. of KMnO_4 and AcOH, and then redeveloping the AgBr image in an ordinary developer. The image is first bleached in $\text{K}_3\text{Fe}(\text{CN})_6$, 20 g.; KBr, 20 g.; H_2O , 1 liter. After washing for 15 min., the residual Ag is removed in KMnO_4 , 5 g.; AcOH 25 cc.; H_2O , 1 l. The image is then treated with a 5% soln. of NaHSO_4 , rinsed and redeveloped in the light. J. I. C.

Effect of washing on desensitized plates. LABORATOIRES DE RECHERCHES PATHÉ CINÉMA. VI* *Congrès internat. photogr.* (Paris) 1925; *Chimie et industrie* 15, 95-6 (1926).—Strips of a given cinematographic film, to which was arbitrarily assigned a sensitiveness of 1000, were desensitized with 0.01% solns. of pinacryptol green, phenosafranine, and a mixt. of sky-blue rhoduline (0.005%) and of acridine yellow (0.015%). The desensitized strips were washed in the dark for periods of 1 min. to 2 hrs., and after drying the sensitiveness was detd. by means of an Eder-Hecht sensitometric screen. With phenosafranine and with the rhoduline-acridine mixt. desensitization was rapidly reduced by washing, and would doubtless be completely eliminated if washing could be prolonged sufficiently without injuring the emulsion. With pinacryptol green desensitization was slightly reduced at the start, and then remained const., showing that this dye is fixed much more strongly than the other dyes and permanently desensitizes the emulsion.

A. PAPINEAU-COUTURE

Emulsions and baryta coating. T. BENTZEN. *Phot. Ind.* 23, 783-5, 4296-8, 1386-7; *Brit. J. Phot.* 73, 59-62(1926).—The conditions are defined which a baryta coating must fulfil for coating photographic papers. Formulas are given and the purpose and effect of each constituent of the baryta coating is discussed. The exptl.

procedure is stated and several emulsion formulas for printing-out papers are recommended. Proof papers are given two coatings of baryta and papers for sep. toning and fixing are usually given 3 or 4 coatings. G. E. MATTHEWS

Light-sensitive photographic materials. S. E. SHEPPARD. U. S. 1,574,943, March 2. A biochem. sensitizing material which increases the general light-sensitiveness of gelatino-Ag-halide emulsions when incorporated with them is prepd. by treating mustard seed, wheat, wheat bran, corn, etc. with alc. or ligroin. U. S. 1,574,944 specifies photographic emulsions comprizing a colloid, particles of photographic Ag salt suspended in the colloid and a sensitizing added compd. such as thiosinamine.

Light-sensitive varnish mixture for photographic use. M. C. BEEBE. U. S. 1,574,356, Feb. 23. A compn. adapted for reproducing designs on metal, glass, etc., comprizes a varnish contg. a light-sensitive oil such as tung oil and an accelerator, e. g., I, which serves to accelerate the selective action of light upon the varnish for photographic purposes. U. S. 1,574,357 (M. C. BEEBE and A. MURRAY) specifies a compn. including a hydrophobic gel-like material such as gelled tung oil sensitive to the action of light, and a catalytic accelerator such as CHI_3 and AlCl_3 . U. S. 1,574,358 (M. C. BEEBE) specifies a process of photographic copying in which compns. of this kind are used. U. S. 1,574,359 (M. C. BEEBE and A. MURRAY) specifies a hydrophobic colloid such as a tung oil compn. and a sensitizer comprizing Pb triethyl iodide.

Color-sensitive photographic emulsions. E. J. WALL and D. F. COMSTOCK. U. S. 1,573,596, Feb. 16. Photographic emulsions are treated with a color-sensitizing dye and an oxidizing agent such as H_2O_2 .

Photographic prints on metal. C. W. CARMAN. U. S. 1,573,478, Feb. 16. A continuous-tone photographic print is applied on the surface of Ag or other metal after the latter has been provided with a series of parallel scratches which serve to reflect light and give added contrast.

Collotype printing plate. W. J. DOBINSON. U. S. 1,574,378, Feb. 23. A base such as glass or metal carries an inner coating of sensitized gelatin insol. in H_2O when unhardened, and an outer adhering coating. The 2 coatings are conditioned by the action of light through a negative and developed by cold H_2O to remove the soft portions of the outer coating and swell (but not remove) the soft portions of the inner coating.

Photographic sensitizer. M. C. BEEBE and A. MURRAY. U. S. 1,575,143, March 2. A sensitizer is formed of a hydrophobic protective colloid such as asphalt in naphtha soln., and a halogen-liberating compd., e. g., Pb triethyl iodide and CHI_3 .

Glass pictures with colored background. W. KIESLING. U. S. 1,574,156, Feb. 23. A transparent plate is coated with a thin layer of chromate glue sol. in the cold and the coated side of the plate is exposed under a reticle negative, the unaltered glue removed from the portions of the plate protected from the light during the exposure and the exposed portions are colored with a dye soln. The entire coated side of the plate is then painted with another color to form a background.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Synopsis of literature concerning the chemical combination of silicon. I. F. PONOMAREV. *Trans. Inst. Exp. Silicates* (Russian) 9, 1-91 (1924).—A comprehensive critical review of the literature pertaining to Si and its compds. for the years 1912 and 1913. J. S. JOFFE

Air oxidation of titanous sulfate solution. Vanadous sulfate, a new and powerful reducing agent. A. S. RUSSELL. *J. Chem. Soc.* 1926, 497-8.—A soln. of titanous sulfate in 4 N H_2SO_4 is not appreciably oxidized during 12 hours' exposure to air. For ordinary purposes, the simplest procedure is to have a soln. of titanous sulfate in 4 N H_2SO_4 and when titanous sulfate is needed, to reduce the vol. required with Zn amalgam. Vanadous sulfate, prepd. in the same way, is a stronger reducing agent, lying between Cd and Sn in its reducing power in 2 N H_2SO_4 . A 0.1 N soln. in 10 N H_2SO_4 is not measurably oxidized by air when kept an hour in a buret. R. J. HAVIGHURST

The oxidation of fixed nitrogen to nitrate at low temperatures and the reduction of nitrate to cyanide. K. A. HOFFMANN, WALTER LINNMANN, HELENE GALOTTI, HERMANN HAGENEST AND ULRICH HOFFMANN. *Ber.* 59, 204-12 (1926).—While the formation of NO at high temps. has been studied exhaustively and applied in industry, little information was available on the formation of nitrites and nitrates at lower temp. and

with the exception of the old expt. of Tuttle (cf. *Ann.* 101, 283(1857)) no chem. reactions are known which could be compared with the formation of nitrate in the soil. The authors found, however, that different compds. contg. N (NH_3 , nitrides, cyanamide, cyanates, cyanides) react with oxidizing agents (KClO_3 , Na_2O_2) in the absence of water, often giving nearly quant. yields of nitrate. The idea is advanced that the oxidation of NH_3 is not a gradual one; the strong affinity of O for N results in the displacement of atoms originally attached to the N atom, e. g., in the formation of KNO_3 from NH_3 and KClO_3 . Since N_2O is an internally satd. compd., its formula being $\text{N}\equiv\text{N}=\text{O}$, no formation of nitrate occurs when it is led over KClO_3 at 360° . (H and CO likewise do not react with hot KClO_3 .) KCNO reacts violently with KClO_3 with formation of KNO_3 , 37.4% N of KCNO having undergone this reaction. Considerable amts. of nitrate are formed on heating urea and Mg nitride with Na_2O_2 or CaCN_2 with BaO_2 . KCNO , NH_3 and CaCN_2 are oxidized by air temps. below 400° in the presence of catalyzers such as Cu or Ni powder, basic Cu carbonate, Ni carbonate, Ag powder or Au (on porous clay), resp. The presence of a small quantity of water vapor in the air promotes the velocity of the reaction. The reduction of nitrate to cyanide is not to be regarded as the inversion of the process of nitrification as explained before, in view of the high temps. required for this process and the great loss of fixed N. The oxidation of NH_3 is carried out on alk. contact masses at low temps. in the presence of suitable catalyzers such as Cu or Ni carbonate, or Ni and Ag powder, resp. The velocity of the reaction increases considerably when the temp. is raised to $380\text{--}400^\circ$. The yield with Ni carbonate is 97%. The presence of impurities (hydrocarbons, sulfides, cyanides, PH_3) does not interfere. Crude CaCN_2 (contg. C and CaO) is oxidized at temps. below 200° when mixed with soda-lime and CuO and exposed to air in a thin layer. At 400° 50% of the N is converted within 3 hrs. Better yields are obtained with Ni carbonate. The amts. of the catalyzers used are rather large, varying from 20 to 50% of the N compd. In all cases nitrite may be found at the beginning of the reaction, proving an intermediate transformation of the tervalent N of NH_3 into the tervalent oxidized N of the nitrite. The subsequent oxidation to the nitrate takes place with considerable velocity.

EMIL KLARMANN

The reaction between sodium sulfit and sulfur. H. J. WATSON AND M. RAJAGOPALAN. *J. Indian Inst. Sci.* 8A, 275-86(1925).—The factors governing the formation of $\text{Na}_2\text{S}_2\text{O}_3$ from S and Na_2SO_3 in aq. soln. were studied. The reaction took place readily above 60° and was appreciably accelerated by rapid stirring. Addn. of an excess of S produced an acceleration approx. proportional to the amt. of S, the reaction being complete in 1 hr. at 80° with 4 mols. S, $22\text{H}_2\text{O}$ and $1\text{Na}_2\text{SO}_3$. Dilm. of the soln. produced a slight increase in the percentage conversion. Addn. of Na_2S in amts. corresponding to 1-4% of the wt. of Na_2SO_3 accelerated the reaction. The velocity of the reaction appeared to depend almost entirely on the rate of soln. of the S and not on the concn. of the Na_2SO_3 . Preliminary treatment of the S with Na_2SO_3 soln. reduced its rate of soln. Flowers of S and roll S were much more efficient than ordinary S. Thionates other than $\text{Na}_2\text{S}_2\text{O}_3$ were not detected in the reaction mixts. The mechanism of the reaction is being investigated further.

K. D. JACOB

The interaction between copper and sulfuric acid. C. W. ROGERS. *J. Chem. Soc.* 1926, 254-69.—Expts. performed at temps. of $16\text{--}270^\circ$ show that there is only one primary reaction, as follows: $5\text{Cu} + 4\text{H}_2\text{SO}_4 = \text{Cu}_2\text{S} + 3\text{CuSO}_4 + 4\text{H}_2\text{O}$. This is followed rapidly (in a few seconds at 270°) by the secondary reactions: $\text{Cu}_2\text{S} + 2\text{H}_2\text{SO}_4 = \text{CuS} + \text{CuSO}_4 + 2\text{H}_2\text{O} + \text{SO}_2$; $\text{CuS} + 2\text{H}_2\text{SO}_4 = \text{CuSO}_4 + 2\text{H}_2\text{O} + \text{SO}_2 + \text{S}$; $\text{S} + 2\text{H}_2\text{SO}_4 = 2\text{H}_2\text{O} + 3\text{SO}_2$. The completed reaction at any temp. is represented by the equation: $\text{Cu} + 2\text{H}_2\text{SO}_4 = \text{SO}_2 + \text{CuSO}_4 + 2\text{H}_2\text{O}$. A white cryst. deposit is anhydrous CuSO_4 , which is at least dimorphous.

R. J. HAVIGHURST

The reciprocal salt pair (Na , Ba)-(Cl, NO_3) in aqueous solution at 20° . ALEXANDER FINDLAY AND JAMES CRUCKSHANK. *J. Chem. Soc.* 1926, 316-8.—The compn. of aq. solns. in equil. with one, two and three salts of this reciprocal salt pair has been detd. with a view to ascertaining the best conditions for the prepn. of $\text{Ba}(\text{NO}_3)_2$ by interaction of BaCl_2 and NaNO_3 . It is found advantageous to use a relatively large proportion of NaNO_3 (about 60% in the initial mixt.) so as to secure as complete a utilization as possible of BaCl_2 .

R. J. HAVIGHURST

Hydrides of the metals nickel, cobalt, iron and chromium. THEODOR WEICHSSELWELDER (WITH BRUNO THIEDE). *Ann.* 447, 64-77(1926).— NiH_2 , CoH_2 , FeH_2 , FeH_3 , and CrH_3 were prepd. by shaking dry H with an ethereal soln. of PhMgBr in which the dry chloride of the metal is suspended. The ethereal soln. becomes colored and a black ppt. seps. out which loses H on being dried. Analysis shows the ppt. to be a hydride. The reaction proceeds as follows: $\text{MCl}_2 + 2\text{PhMgBr} = \text{MPH}_2 + \text{MgBr}_2 +$

$MgCl_2$; $MPh_3 + 2H_2 = 2C_6H_6 + MH_3$. M is the metal under investigation. $FeCl_3$, which is sol. in ether, reacts very rapidly with $PhMgBr$ and also takes up H more rapidly than the other substances. $CrCl_3$, although sol. in ether, takes up H very slowly. W has been observed to form a hydride in a similar manner. R. J. H.

Pseudohalides of quadrivalent lead. H. P. KAUFMANN AND F. KÖGLER. *Ber.* 59, 178-86(1926).—The application of $Pb(AcO)_4$ in the prepn. of free $(SCN)_2$ from HSCN (cf. C. A. 20, 50) suggested its use in an attempt to prep. free $(SeCN)_2$. When a soln. of $Pb(OAc)_4$ in chloroform was added to a cooled soln. of $KSeCN$ in dry acetone, $Pb(SeCN)_2$ pptd. and the soln. contained free $(SeCN)_2$, or possibly the compd. $K(SeCN)_2$. On addn. of antipyrine and evapn. of the solvent the *di-antipyrinyl selenide* (*bis-(1-phenyl-2,3-dimethyl-5-pyrazolonyl-4)selenide*) was isolated, colorless crystals from benzene, m. 236° . $(SeCN)_2$ is decomposed by water with the formation of H_2SeO_4 , HCN and $HSeCN$; H_2SO_4 , HCN and HSCN are produced from $(SCN)_2$ and H_2O . When the soln. is not kept neutral or alk., $HSeCN$ decomposes with formation of Se. It is assumed that the decompn. of $(SeCN)_2$ takes place in 2 stages, the intermediate products being $HOSeCN$ and HO_2SeCN . The reaction between I and $HSeCN$ may be used for the detn. of the latter. When a soln. of $(SeCN)_2$ in CS_2 is heated under reflux a rearrangement takes place with formation of $Se_3(CN)_2$ and $Se(CN)_2$, which were first obtained by Verneuil (cf. *Ann. chim. phys.* [6] 9, 353(1883)) and correspond with the analogous S compds. The same compds. are formed when Se_2Br_2 reacts with $AgCN$ in the presence of Et_2O . An attempt was also made to prep. free oxycyanogen, the radical of cyanic acid, by the action of $Pb(OAc)_4$ on $HCNO$ in $CHCl_3$ soln. No production of CNO was observed and the resulting sirupy product is regarded as $Ph(OCN)_4$. EMIL KLARMANN

The system ferrous oxide-phosphoric acid-water and some of its oxidation products. S. R. CARTER AND N. H. HARTSHORNE. *J. Chem. Soc.* 1926, 363-74.—In an atm. of CO_2 , at 70° , the system $FeO-P_2O_5-H_2O$ was studied between the concns. 7.38 and 57.51%, P_2O_5 . Within this range the stable solid phases are the acid salts $FeO \cdot P_2O_5 \cdot 4H_2O$, $2FeO \cdot P_2O_5 \cdot 3H_2O$, and a new compd. $2FeO \cdot P_2O_5 \cdot 5H_2O$. By the oxidation of phases poor in acid, two neutral ferric phosphates, both having the compn. $Fe_2O_3 \cdot P_2O_5 \cdot 4H_2O$, are deposited. The brown β -form exists in contact with liquid phases having high to medium concns. of ferrous iron; at lower concns., the pink α -form becomes stable.

R. J. HAVIGHURST

The two varieties of mercuric oxide and the direct formation of oxychlorides and oxybromides. H. PÉLABON. *Bull. soc. chim.* 39, 201-2(1926).—See C. A. 19, 1105, 2308. E. H.

Synthetic potassium and sodium chromosilicates. (MLLE.) H. KARFIOL. *Roch. ki Chem.* 5, 182-92(1925).—Synthetic chromosilicates of Na and K are prepared by the fusion of mixts. in various proportions of Cr_2O_3 , Na or K chloride and carbonate and silica. The fused mass, after being heated for 10 hrs., is extd. with water. In the case of mixts. with K, the residue thus obtained had so low a K content that most of them appeared to be compds. of Cr_2O_3 and silica in various proportions, the K present being probably an impurity. The only product of this type which appeared definitely to be a chromosilicate had a compn. corresponding with the formula $K_2Cr_2Si_3O_{13}$. The cryst. nature of these substances could not be detd., because of the extremely small size of the particles. The Na chromosilicates obtained are of very complicated compn. and seem to be additive compds. of Na silicate and oxide to chromosilicates of the same type as the known series of aluminosilicates, $R_2Al_2Si_nO_{3n+4}$. All the Na chromosilicates prepd. are isomorphous, in spite of considerable differences in compn., the proportions of Cr_2O_3 to Na metasilicate being as 1:2, 3, 4, 5, 6, 7 and 8. B. C. A.

Monohydrate of borax. M. RAKUZIN AND A. NESMEIANOV. *Mitt. wiss.-tech. Arb. Rep.* (Russia) 13, 52-4(1924).—The monohydrate of Na tetraborate (borax) may be obtained pure by heating the decahydrate at 180° to const. weight. B. C. A.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Some ideas on the future of analytical chemistry. A. LASSIEUR. *Rev. sci.* 63, 613-6(1925).—A plea for more theory and less cook-book procedure in teaching analytical chemistry. A. PAPINEAU-COUTURE

Sources of error in electrolytic analyses. BOEHM. *Chem.-Ztg.* 50, 109(1926).—The possibility of the deposition of Pt on the cathode after it has been dissolved from the anode is pointed out and the danger of deposition of Mn with Ni is suggested.

These errors are particularly noticeable in working in laboratories which are heavy with fumes and in which the current is variable. W. T. H.

Use of hydrazine sulfate in iodometry. E. CATTELAINE. *J. pharm. chim.* [8] 2, 387-91(1925).— $N_2H_4 \cdot H_2SO_4$ may be used as a standard substance in the titration of I solns., on account of the ease of its purification, its stability in solid form or in aq. soln. and its quant. oxidation by I as follows: $N_2H_4 + 2I_2 = 4HI + N_2$. S. W.

The use of certain organometallic complexes in gravimetric analysis. E. CATTELAINE. *J. pharm. chim.* [8] 2, 485-91, 525-35(1925).—A summary of the use of dimethylglyoxime, diphenylglyoxime, dicyanodiamidine, 1-nitroso-2-naphthol, cupferron and K ethylxanthate for the sepn. and detn. of Ni and Co, Ti and Al, etc., with detailed account of the analytical characters of each ppt. Some recently proposed org. reagents for the quant. sepn. of Ni, Co, Al, etc. (*C. A.* 16, 2460, 3826-7; 17, 2251, 2417; 19, 1548, 1833) are as yet untried. S. WALDBOTT

Analysis of tungsten steels. F. FETTWIS. *Stahl u. Eisen* 45, 1109-10(1925).—Addn. of phosphoric or tartaric acids to the H_2SO_4 - HNO_3 mixt. used in dissolving W steel serves to retain the W in soln. After adding H_3PO_4 the soln. is ready for the detn. of Cr by the persulfate process without filtration, but both phosphoric and tartaric acids interfere in the Mn detn. by the persulfate-arsenite method. For the cyanometric detn. of Ni in W steel, tartaric acid is used to keep the tungstic acid in soln., and $Na_2P_2O_7$ is added to render the soln. sufficiently pale-colored when made ammoniacal before titration. The Ni dimethylglyoxime ppt. from such a soln. invariably retains WO_3 , so that the Ni results are 0.05-0.1% too high. B. C. A.

Commercial practice in sampling and assaying copper. A. M. SMOOT. *Eng. Mining J.-Press* 120, 605-11(1925).—This paper is of interest to the mining engineer who has not time to read the extensive literature on the subject and shows in particular how some of the losses of metal shown on the balance sheet may be more or less fictitious. W. T. H.

Method for the determination of vanadium in ferro-vanadium. KINICHI SOMEYA. *Sci. Repts. Tôhoku Imp. Univ.* 14, 577-91(1925); cf. *C. A.* 19, 796.—The H_2SO_4 soln. contg. V is oxidized by $K_2Cr_2O_7$ and then titrated with $FeSO_4$ with diphenylamine as indicator. W. T. H.

The estimation of tin in non-ferrous alloys. H. NORRISON MARR. *Metal Ind.* (London) 27, 77-8(1925).—The method is an adaptation of Beringer's method and consists in oxidizing the alloy with 6 N HNO_3 , evapg. to dryness and taking up the residue in HNO_3 , filtering off SnO_2 and Sb_2O_3 , igniting this residue with very fine Zn and ZnO to reduce the Sn and Sb to the metallic condition, dissolving in HCl, reducing with Ni and titrating with $SbCl_2$. W. T. H.

Method for the detection and determination of mercury by means of aluminum. PAUL DENIS. *Ann. méd. légale* 1, 348-9(1921).—The method is based on the decompn. of H_2O in the cold by Al in the presence of Hg. With fine Al filings weighing about 0.01 mg. each the H liberated adheres to the Al and carries it to the surface, where the H escapes, allowing the Al to sink. The test is extremely delicate and can give positive results with solns. contg. only 10^{-9} $HgCl_2$. The acid radical can be detd. quant. in the soln., and the Hg calcd. therefrom. A. PAPINEAU-COUTURE

The dichromate method for the determination of iron. A. BESOMBE. *Bull. soc. chim. Belg.* 34, 338-41(1925).—A slight improvement in the operating technic is described. W. B. PLUMMER

Analysis of copper-palladium-gold-silver concentrates. C. W. DAVIS. *Bur. Mines. Repts. of Investigations* No. 2731, 5 pp.(1926).—In Alaska a concentrate is produced contg. 40-50% Cu and considerable Pd, Au and Ag. Results obtained by different assayers on Pd, Au and Ag varied so much that the Bureau of Mines was asked to develop a suitable method of analysis. Five procedures were tested and the following proved to be the most satisfactory on the whole. Fuse 0.5 assay ton with 90 g. PbO , 5 g. borax glass and some Na_2CO_3 . For the detn. of Pd, add 10 mg. of Ag per mg. of Pd to the charge. After melting, pour in the usual way. The button is usually too brittle to hammer. Therefore, add Pb and scorify the buttons twice singly and then in pairs, finally scorifying singly and then cupelling. Part the beads as usual with dil. HNO_3 , anneal and weigh the Au. Ppt. the Ag with HCl, filter and wash with hot water. (For the Ag detn. do not add Ag at the start.) Evap. the filtrate with HCl to dryness twice on the water bath, moisten the last residue with 2 drops of HCl, add a little water, filter and ppt. the Pd with a little dimethylglyoxime reagent. *Filter, ignite in H_2 and weigh as Pd. W. T. H.

The entrainment of magnesium by aluminum. A. LASSIEUR. *Compt. rend.* 182, 384-6(1926).—Pariselle and Laude (*C. A.* 19, 2923) have recommended adding a

very large excess of NH_4Cl in order to prevent pptn. of Mg with Al upon adding NH_4OH . It is here pointed out, however, that the pptn. of Al as hydrated oxide takes place preferably in a soln. to which only enough NH_4OH has been added to make the p_{H} equal to 7. Under such conditions it is not necessary to provide as much NH_4Cl as recommended by Pariselle and Laude, who evidently added too much NH_4OH . W. T. H.

Determination of zinc oxide in brass. B. S. EVANS AND H. F. RICHARDS. *J. Inst. Metals* (preprint) 7 pp. (Mar., 1926).—When the attempt is made to det. O in brass by simply heating in H_2 and weighing the H_2O formed, the results are invariably too low; the trouble has been traced to the volatilization of Zn and condensation of ZnO from the vapors. This trouble can be prevented by placing rolls of Cu in the furnace on both sides of the sample and heating not higher than 1000° . W. T. H.

Estimation of oxygen and sulfur in refined copper. W. H. BASSETT AND H. A. BEDWORTH. *Trans. Am. Inst. Mining Met. Eng.* 1926, No. 1526F, 14 pp.—By heating in H_2 , the O is liberated as H_2O and the S as H_2S , both of which products can be absorbed and weighed. It is sometimes more convenient to weigh the residual metal, calling the loss in wt. O and S. Detailed directions are given for carrying out both detns. W. T. H.

Determination of potassium as cobaltinitrate. L. LE BOUCHER. *Anales soc. españ. fis. quim.* 23, 540–50(1925).—Directions are given for obtaining a normal ppt of $\text{NaK}_2\text{Co}(\text{NO}_2)_6 \cdot \text{H}_2\text{O}$. Emphasis is placed on dropwise addn. of the reagent, prolonged stirring while the ppt. is forming, and allowing to stand overnight before filtering. The drying temp. should not exceed 110° . The method is accurate when the Na content of the soln. is not over 15 times that of the K. With more Na it is best to dissolve the ppt. and repeat the pptn.: in such cases an error of 1% is likely. E. M. S.

Analysis of commercial magnesium. R. GUÉRIN. *Ann. chim. anal. chim. appl.* 8, 34–40(1926).—According to the French Commission, Mg obtained by electrolysis of the chloride is classified into metal contg. over 99.7% Mg and metal contg. 99.2–99.7% Mg. For metal of such purity, special precautions are necessary in the analysis so that detailed directions are prescribed for the accurate detn. of Cl, Si, Fe, Mn, Cu, Pb, Al, Zn and Ca. The methods are well chosen. W. T. H.

Determination of rubidium and cesium. W. STRECKER AND F. O. DIAZ. *Z. anal. Chem.* 67, 321–41(1925).—Dissolve the mixt. of KCl, RbCl and CsCl in as little water as possible and add a mixt. of 2 parts alc. and 1 part concd. HCl. This causes pptn. of the greater part of the KCl. Filter, wash the ppt. with abs. alc., dry at 110° and weigh. In the filtrate, ppt. Rb_2SnCl_6 and Cs_2SnCl_6 at the boiling temp. by means of boiling soln. of SnCl_4 in alc. Filter and det. the residual K by the HClO_4 method after evapg. off the alc. Dissolve the Rb-Cs ppt. in tartaric acid soln., ppt. the Sn with H_2S , filter, evap. to dryness and destroy the tartaric acid by igniting. Dissolve the residual salts together with an equal amt. of FeCl_3 or NaCl in the least possible vol. of water. Add 50 cc. of AcOH per g. of the mixt., heat to boiling and add a satd. soln. of SbCl_5 in AcOH . Heat 1 hour on the water bath and then allow to stand overnight. Filter off the ppt. of $\text{Cs}_3\text{Sb}_2\text{Cl}_9$ and wash with a 5–10% soln. of SbCl_5 in AcOH . Dissolve the ppt. with HCl and det. the Cs as CsClO_4 . In the filtrate, remove all Sb as Sb_2S_3 , by dilg. and introducing H_2S , and det. Rb as perchlorate. Tests with this procedure, using approx. 0.5 g. of each chloride, agreed remarkably well considering the difficulties involved. Interesting data are given concerning the accuracy of the detn. of Rb as RbClO_4 , reduction of RbClO_4 by fusion with soda and niter and titration of the chloride thus formed, reduction of RbClO_4 with hydrazine sulfate and titration of the chloride, detn. of Cs as CsClO_4 , reduction of CsClO_4 and titration of the Cl, pptn. of Rb and Cs with cobaltinitrite reagent and the analysis of the ppts. and pptn. of Rb and Cs with SnCl_4 and SbCl_5 . Some 167 expts. are described. W. T. H.

Separation of iron and aluminum from zirconium. RUDOLF LÉSSING. *Z. anal. Chem.* 67, 341–52(1925).—To the soln. of Fe, Al and Zr in dil. HCl or HNO_3 , add dil. NH_4OH until no further pptn. is noticeable; then add a slight excess of NH_4OH , 100 cc. of a cold, satd. soln. of $(\text{NH}_4)_2\text{CO}_3$ and enough water to bring the vol. to approx. 400 cc. In some cases it is well to add about 2 g. of NH_4Cl at the start, to prevent the formation of a colloidal soln. After the addition of the carbonate, heat gradually to $70\text{--}80^\circ$ and maintain this temp. for 5–10 min. Filter, wash with hot water, dissolve in dil. HCl and repeat the above treatment. Upon ignition, the last ppt. yields Fe_2O_3 and Al_2O_3 . In the combined filtrate, the Zr can be pptd. as $\text{Zr}(\text{OH})_4$ by NH_4OH after making slightly acid and evapg. to about 400 cc. It is probable that the solv. of Zr^{++++} in $(\text{NH}_4)_2\text{CO}_3$ soln. is due to the formation of the complex anion $[\text{Zr}(\text{CO}_3)_3]^{--}$. W. T. H.

Determination of nicotine by the method of Ulex. F. MACH AND F. SINDLINGER

Z. anal. Chem. **67**, 369–86(1926).—Tobacco ext. is now used so much as a fungicide* that the detn. of nicotine is a matter of some importance. The various methods which have been used for the detn. of nicotine are outlined and a bibliography of 36 papers on this subject is appended. It has been known for some time that the Ulex method gave higher results than most, if not all, other methods and a careful study of the details shows that there are so many sources of error that no reliance can be placed upon any results obtained with it. Some nicotine is lost during the analytical procedure but in the distn. considerable NH_3 is formed, which is titrated subsequently with the nicotine. The method is so faulty that it shows very appreciable quantities of nicotine present in such substances as hay, cabbage leaves and tomato leaves, which positively do not contain any nicotine. The method of Ulex must be discarded. W. T. H.

Determination of cerium in alloy steel. K. SWOBODA AND R. HORN. *Z. anal. Chem.* **67**, 386–98(1926).—On the basis of some 37 expts. which are here recorded and discussed, the following method is suggested for the detn. of Ce in high-speed steel. Treat 2 g. of sample with 60 cc. of 6 N HCl in a 500-cc. beaker. After the sample has all dissolved, add dropwise sufficient HNO_3 to insure the complete oxidation of the Fe and W. To the hot soln. add at once 60 cc. of 25% tartaric acid soln. and 30–35 cc. of SnCl_2 in HCl. This serves partly to reduce the Fe and W. Add a slight excess of NaOH soln. and transfer to a 500-cc. measuring flask. After the liquid has become cool, add 10 cc. of alc. and make up to the mark. Mix and filter, using a superposed funnel to avoid oxidation as much as possible. The ppt. contains hydroxides of Fe, Mn, Co, Ni and metallic Ta and there are present in the filtrate cerous tartrate, chromic tartrate and the tartrate complexes of the Na salts of WO_3 , MoO_3 , V_2O_5 and W_2O_5 . Take 250 cc. of the alk. filtrate in a 500-cc. beaker and make slightly acid with HCl. Heat to boiling, remove the flame and ppt. the Ce as CeF_4 by adding 2 g. of solid NH_4F . Neutralize the supernatant liquid with NH_4OH , add 1–2 drops of HCl and filter after 1 hour. Wash with hot water contg. 3 g. NH_4Cl per l. Ignite and weigh as CeO_2 . W. T. H.

The iodometric determination of arsenic acid. B. ORMONT. *Z. anal. Chem.* **67**, 417–26(1926).—The principle involved is identical with that of Gooch-Browning so often used in the analysis of commercial Pb arsenate. The As is reduced to the tervalent condition by means of KI in 15–20% H_2SO_4 . The liberated I_2 is expelled, for the most part, by passing a mixt. of CO and CO_2 through the soln., and the last traces by means of H_2SO_3 . Eventually the tervalent As is oxidized by titration with I_2 in the presence of NaHCO_3 . W. T. H.

Determination of nitrogen by the Kjeldahl method. A. C. ANDERSEN AND B. N. JENSEN. *Z. anal. Chem.* **67**, 427–48(1926).—In this paper some 88 expts. are described in the study of the sources of error in the Kjeldahl detn. As a result of this study the conclusion is drawn that if 20 cc. of H_2SO_4 , 10 g. of K_2SO_4 , 1 g. of CuSO_4 crystals and 0.75 g. of HgSO_4 are used, and the digestion is accomplished by very gentle but steady boiling of the liquid—adding a little graphite if necessary to prevent the danger of overheating—and if, moreover, care is taken to avoid loss of H_2SO_4 , then the N of proteins and similar substances can be converted without loss into NH_4HISO_4 . After the liquid has become clear (green), 2–4 hrs.' heating usually suffices; with some difficultly decomposable substances, more prolonged heating is necessary. If the substance to be analyzed contains considerable chloride, it is advisable not to add the HgSO_4 until all the HCl has distd. off. To remove the Hg from soln. it is best to add Na_2S but the excess of sulfide should be pptd. by adding a little Cu soln. If Hg is used as contact substance, glass flasks are better than Cu ones for the distn. A trap is shown which prevents spattering when Zn is not added. Pumice also prevents bumping. The NaOH added to liberate NH_3 must be free from nitrite. W. T. H.

Determination of perchlorate in Chili saltpeter on the basis of precipitation with methylene blue. K. A. HOFMANN, FRIDOLIN HARTMANN AND ULRICH HOFMANN. *Ber.* **58B**, 2748–54(1925).—The proposed method is suitable for the detn. of 0.4–0.8% of KClO_4 in samples of NaNO_3 . By using the so-called "methylene blue B extra" in 0.1% soln., a sensitive reagent is obtained for the pptn. of KClO_4 . An approx. idea of the amt. of KClO_4 present can be obtained by noting the rate of formation of the ppt. on adding the reagent to a 20% or 10% soln. of the nitrate. The actual amt. can be estd. from the color of filter paper that has been moistened with the soln. and methylene blue and then dried, or by colorimetric comparison with known amts. of KClO_4 added to pure NaNO_3 . It is interesting to note that the soly. of the ppt. is less in NaNO_3 soln. than it is in water, because of a salting out effect. The compn. of the ppt. also varies according to the menstruum from which it is pptd. and approaches the ideal compn. of 1 mol. of dyestuff to 1 KClO_4 only in very dil. solns. The most sensitive

test for KClO_4 is by means of a satd. soln. of the methylene blue perchlorate itself with which 0.04% of KClO_4 can be estd. W. T. H.

Analysis of lime. J. C. BAILLAR. *Ind. Eng. Chem.* 18, 389-90(1926).—Three methods are described for the detn. of CaO . (1) Weigh 1 g. of lime into a dry flask and treat with 500 cc. of boiling water. Add an excess of 0.3 N I_2 soln. and titrate the excess with $\text{Na}_2\text{S}_2\text{O}_3$. (2) Weigh 1 g. of lime into a dry flask and hydrate by adding 500 cc. of boiling water. Add 25-50 cc. of NaOH soln. (of strength equiv. to the ZnCl_2 soln.) and 0.5-1 cc. of an indicator made by mixing a 1% soln. of phenolphthalein in alc. with a 0.4% soln. of alizarin-cyanine-green in water. Add standard 2.5% ZnCl_2 soln. until a fairly permanent green color is obtained and then an excess of 10 cc. After 10 min. titrate to a lavender shade with NaOH . (3) Weigh 5 g. lime into a dry flask and add 150 cc. of boiling water. Shake till the CaO is hydrated, add 40 g. of sugar and shake till the lime is dissolved. Use an aliquot part of the filtered soln. for titration with NaOH with phenolphthalein as indicator. W. T. H.

Benzoylmethylglyoxime as a precipitant of palladous salts. J. HANUŠ, A. JILEK AND J. LUKAS. *Chem. News* 131, 401-2(1925); 132, 1-4(1926).—Benzoylmethylglyoxime, in 2% alc. soln., appears to be a sp. reagent for Pd. To 100-200 cc. of boiling HCl -Pd-soln. add the reagent in 40% excess, boil a few min., let stand 12 hrs., filter, wash with dil. HCl and then with water, dry at 105° and weigh. The dry ppt. contains 20.64% Pd. The yellow ppt. is sol. in NH_4OH but insol. in water and dil. HCl . If Pt, Ir, Rh, Os or Au is present add 1-6 cc. of HCl before adding the reagent. If Sb is present add tartaric acid. In the presence of Mo, W and V, add KH_2PO_4 besides HCl . The presence of Bi, Cd, Hg, As, Sn, Fe, Ni, Co and Zn does no harm if HCl is present. The formula of the ppt. is $\text{C}_{20}\text{H}_{18}\text{N}_4\text{O}_6\text{Pd}$. W. T. H.

The reliability of vacuum analysis for solid metallic hydrides. E. J. WEEKS. *Chem. News* 132, 17-8(1926).—Loss of wt. after heating in a vacuum gives better results in the analysis of metal hydrides than does the attempt to measure the H_2 liberated. W. T. H.

Crucible methods of analysis. J. D. MAIN SMITH. *Chem. News* 132, 65-72 (1926).—Instead of using open crucibles, as is the common practice in gravimetric analysis, or crucibles with lids fitting on top of the crucible, the use of "interior-fitting, serrated lids" is advocated for igniting ppts. The lid prevents loss by spattering if the heating is too rapid and the serrations on the sides of the lid permit escape of gases. The advantages of gravimetric over volumetric analysis are pointed out in numerous instances. W. T. H.

Some new, very sensitive methods based on the measurement of gaseous volumes. LOUIS HACKSPILL and GEORGES D'HUART. *Ann. chim.* 5, 95-133(1926).—*I. New volumetric method of elementary analysis.*—In a single sample weighing 20 mg., it is possible to det. C, O and N with remarkable accuracy. The principle of the method consists in heating the org. substance in an evacuated vertical tube. The substance is covered with a column of CuO to insure complete oxidation and on top of this there is a reduced Cu spiral to insure reduction of oxides of N. The evolved gases are chilled to -80° , which causes congelation of H_2O . The residual gas is measured before and after the CO_2 is absorbed by KOH and $\text{K}_2\text{S}_2\text{O}_8$. From the chilled tube, H_2O is allowed to evap. and after contact with CaH_2 the liberated H_2 is measured. *II. Detn. of water in a gas mixture.*—The principle of the method is the same—condensation of the water by evacuating and chilling, contact with CaH_2 and measurement of the liberated H_2 . In order to get accurate results with small samples it is necessary to take special precautions, which are enumerated in detail. *III. New method for determining carbon in steel.*—The steel is dissolved in 6 N HCl , a very strong soln. of CrO_3 is added and the system is evacuated. The gases pass through a condenser, as in the Corleis method then through a tube chilled to -80° , which condenses H_2O and Cl_2 , then through a hot furnace contg. CuO , and finally into a tube chilled to -190° , which condenses the CO . As compared with the Corleis method, the method is not unduly tedious, but it cannot be as rapid as the dry combustion method now in use in most steel labs. W. T. H.

Sensitive and specific reaction for nitrate and for hydroxylamine. JAKOB BLOM BER. 59, 121-5(1926).—*Reagents.*—(1) Water free from nitrate and nitrite, prepd. by boiling tap-water with Zn and H_2SO_4 and distg. from a flask provided with a Hopkins' trap. (2) 10 g. sulfanilic acid dissolved in 1 l. of 30% AcOH . (3) 3 g. of α -naphthylamine boiled with 700 cc. of water, the clear soln. decanted off from the bluish violet residue and treated with 300 cc. of AcOH . (4) 1.3 g. I_2 dissolved in 100 cc. of AcOH . (5) 2.5 g. $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ in 100 cc. of water. (6) 0.7 g. NaNO_2 in 100 cc. of water. (7) Nitrate- and nitrite-free Zn dust, prepd. by heating Zn dust for 1 hr. on the water bath with very dil. AcOH cooled, treated with more AcOH , filtered, washed and dried

All these reagents must be tested to make sure that they are free from HNO_2 or HNO_3 . Since mineral acids interfere with the test for nitrite, they must be weakened by adding AcONa . The tests depend upon the formation of HNO_2 , by reduction of a nitrate or by the oxidation of NH_4OH , after the removal of any nitrite that may have been present originally. Treat about 5 cc. of the AcOH soln. to be tested with 1 cc. each of the above reagents (2) and (3). If no red coloration results, there is no nitrite present, and the soln. can be used directly for the test for HNO_3 . Add a small piece of Zn , or a few centigrams of Zn dust, and if nitrate is present a red coloration will result, eventually with pptn. of the azo dyestuff if much nitrate is present. To test for NH_4OH in the absence of HNO_2 , treat the original AcOH soln. with 1–2 cc. of reagent (2) and then 0.5 cc. of (4). Shake well and after 2–3 mins. remove the excess I_2 by dropping in reagent (5), using a slight excess. Add a little of reagent (3) and a red coloration should result if NH_4OH was originally present. If the original soln. gave the test for nitrite, this must be removed and its decompn. is best effected by means of *p*-diazobenzenesulfonic acid, which is formed by diazotization of sulfanilic acid. Other methods are likely to cause trouble with the test for NH_4OH . To the AcOH soln. under examn. add an excess of reagent (2). After a few minutes the diazotization may be regarded as complete. Heat 3–4 minutes on the water bath or over a free flame to decompose the excess of diazobenzenesulfonic acid. If considerable nitrite was present the soln. will be yellow. To make sure that the HNO_2 was all removed, test a little of the soln. with a few drops of reagent (3). Next make sure that an excess of (2) was added by testing with a drop of (6). Then test as above for HNO_2 and NH_4OH . If large quantities of HNO_2 are present and it is desired to test only for nitrate, it is best to remove the greater part of the HNO_2 by heating with $(\text{NH}_4)_2\text{CO}_3$, afterward adding AcOH and treating as above for the removal of the last traces of HNO_2 . W. T. H.

The potentiometric control of diazotization and the determination of amines. ERICH MÜLLER AND ERNST DACHSELT. *Z. Elektrochem.* 31, 662–6(1926).—Expts. were made in diazotizing aniline, *m*-xylydine, tolidine and aminoazobenzenedisulfonate of Na . It was found in all cases that when the end point was reached, a slight excess of NaNO_2 caused a distinct indication with the indicator electrode. With a little more NaNO_2 the test with iodo-starch paper could be obtained. In the expts. the soln. of the amine was placed in a glass beaker, which was provided with a stirrer and a Pt electrode connected with the *N* calomel electrode in the usual Poggenдорff-Ostwald way. Max. points in the plotted e. m. f. curve was obtained in all 4 of the above cases at +0.54–0.59 volt. The curve is so steep that it is feasible to titrate with an indicator electrode corresponding to this e. m. f. and titrate till the galvanometer shows a permanent zero reading. Such an indicator electrode can be prepd. with Pt foil dipping into a soln. of the same acidity as that of the soln. under examn. and to which 1 cc. of 19.2% NaNO_2 is added for each cc. of soln. The method can be used for the detn. of the amine content as well as for the control of technical diazotizing operations. The results are accurate at 20° but attempts to accomplish acceleration by raising the temp. were abortive. W. T. H.

The absorption of carbon monoxide by cuprous chloride. LUDWIG MOSER AND FRANZ HANIKA. *Z. anal. Chem.* 67, 448–56(1926).—As a result of numerous expts. the conclusion is drawn that the most suitable concn. for an acid Cu_2Cl_2 soln. contains the following parts by wt., Cu_2Cl_2 16–18, concd. HCl 24–27, H_2O 60–55. The addition of 0.2–0.3 g. $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ accelerates the reaction. For an ammoniacal soln. the most favorable concn. is Cu_2Cl_2 11–12, NH_3 13–14, H_2O 76–74. This soln. is unquestionably more efficient, only 11 parts by wt. of Cu_2Cl_2 being required to absorb 30 cc. of CO , and 16 parts Cu_2Cl_2 being required in the presence of HCl . The dispute of nearly 75 years' standing with respect to the relative advantages of the 2 absorbents seems to be settled in favor of the ammoniacal soln. Expts. with $\text{K}_3\text{Fe}(\text{CN})_6$ showed that in the presence of Hg as catalyzer it can be used for absorbing CO but the rate of absorption is too slow. W. T. H.

A simple means of avoiding entrainment in distilling ammonia in the micro-Kjeldahl method. LEO PICK. *Z. Zuckerind. cecoslov. Rep.* 50, 141–2(1925); *Listy Cucrov.* 43, 557(1924–5).—Charcoal (best official basswood charcoal) is boiled with NaOH and ignited. 20 to 100 mg. added to a Kjeldahl flask is ample to prevent entrainment of alkali. W. L. BADGER

The determination of invert sugar in the presence of sucrose. II. R. OFNER. *Z. Zuckerind. cecoslov. Rep.* 50, 65–71(1925); cf. *C. A.* 19, 583, 3445.—O. finds that his soln. reduces 2.6 mg. Cu per mg. invert in a soln. contg. 0.01% invert. This drops to 2.0 mg. Cu at 0.05% invert, 1.8 mg. at 0.1%, 1.5 mg. at 0.2%, and 1.0 mg. at 1.0%. His standard soln. contains 80 g. $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$. A series of solns. was made up

contg. varying amts. of Na_2HPO_4 and Na_3PO_4 . With sucrose alone, the soln. contg. only Na_2HPO_4 ppts. no Cu when boiled according to directions. As Na_2HPO_4 is replaced by Na_3PO_4 the amt. of Cu pptd. by sucrose alone increases, but the net amt. of Cu pptd. by invert increases, and also the amt. of Cu pptd. by invert becomes more nearly const. with changes in invert content. A soln. contg. 40 g. $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ and 40 g. $\text{Na}_3\text{PO}_4 \cdot 10\text{H}_2\text{O}$ ppts. 5.0 mg. of Cu from 10 g. pure sucrose; but ppts. 2.7 mg. Cu per mg. invert at all concns. of invert between 0.01 and 0.5%. If this soln. is to be used on a sample contg. over 50 mg. invert in a 10 g. sample, a smaller sample should be used and made up to 10 g. with refined sucrose. W. L. BADGER

Salt solution as a confining liquid in gas analysis. F. G. HOFFMANN. *Z. angew. Chem.* 39, 23-4(1926).—Concd. NaCl soln. has been used as confining liquid in gas analysis but recently it has been proposed to add a little acid to the NaCl soln. Whereas the use of NaCl soln. is advantageous because most gases are less sol. in brine than in pure water, it is pointed out that there is no advantage gained by adding acid but, on the contrary, the use of acid is likely to cause error. W. T. H.

Analysis of gases from rocks by microchemical methods. NICOLAS METTA *Annuar. Inst. Geol. Romaniei* 10, 85-119(1925). (In French.)—The analysis of gas is made under const. vol., in a volumeter of previously detd. capacity and placed in communication with a MacLeod manometer modified to show 0.001 mm. of pressure. Operating under an initial pressure of 3.5 to 4 mm., detns. may be made with 0.001 of the vol. required by the ordinary methods of gas analysis. The construction and calibration of the app. are described, also the procedure and calcs. in the detn. of gases in several samples of rock. L. W. RIGGS

Spectrographic analyses of residues of mineral water. I. Water of Salsomaggiore. C. PORLEZZA AND A. DONATI. *Ann. chim. applicata* 15, 535-42(1925).—Spectrographic examn. by a modification method of Urbain (C. A. 18, 2862) and chem. analyses of Salsomaggiore water showed the presence of Na, K, Li, Mg, Ca, Sr, Ba, Al, Fe, Mn, Si and B, and no element was found by one method and not by the other. A detn. of Ba was also attempted spectrographically by an improvised method. NaCl was intimately mixed with 1% of BaO and spectrograms were obtained of this mixt. and of mixts. prepd. from this mixt. by dilg. progressively with more and more NaCl. The spectrogram of the water residue was practically identical with the artificial mixt. contg. 0.01% BaO, from which it was calcd. that Salsomaggiore water contained 0.0162 g. of Ba per l. Previous chem. detns. of Ba give no quant. data, only traces being reported. The results in general indicate that spectrographic examn. is as reliable as chem. analysis for identifying the elements present in the residue of a water, but that the examn. must extend from the green to the ultra-violet and must not be confined to the region prescribed by the original method of Urbain. C. C. DAVIS

Determination of quinone with thiosulfate. J. RZYMKOWSKI. *Z. Elektrochem.* 31, 371-82(1925).—Several methods for detg. quinone iodometrically have been proposed. A study of the equil. between quinone + $\text{I}^- + \text{H}^+$ and hydroquinone + I_2 shows that the equil. const. is 2.9×10^{-6} , which explains why somewhat divergent results are obtained under slightly different conditions when it is attempted to reduce quinone by HI. Now it happens that quinone acts directly with thiosulfate, the final reaction being represented by the equation $2\text{C}_6\text{H}_4\text{O}_2 + 4\text{H}^+ + 2\text{S}_2\text{O}_3^{--} \longrightarrow \text{C}_6\text{H}_2(\text{OH})_2(\text{S}_2\text{O}_3\text{H})_2 + \text{C}_6\text{H}_4(\text{OH})_2$. This reaction can be used for the direct titration of quinone. The end point can be based upon the color of the quinone soln. itself or upon the color obtained in a spot test with Wurster's soln. of dimethyl-*p*-phenylenediamine. It is also possible to det. the end point electrometrically. For the titration take about 0.4 g. of quinone, dissolve in 4 cc. of AcOH and dil. to 100-150 cc. W. T. H.

Formol titration of certain amino acids. S. L. JODIDI. *J. Am. Chem. Soc.* 48, 751-3(1926).—Cystine can be detd. accurately by the formol titration method. Titration of hippuric acid with standard alkali yields a result as accurate as that obtained by the formol titration, there being no advantage in the application of the latter method. The formol titration apparently indicates about 87% of tryptophan. C. J. WEST

Analysis of ternary mixtures, particularly of acetone, alcohol and water. ERWIN BENESCH. *Chem.-Ztg.* 50, 98-9(1926).—A general method is explained based on the detn. of the d. and the direct detn. of one of the constituents. Thus in the mixt. of acetone, alc. and water, the acetone is first detd. by the iodometric method of Messinger. Then, with the aid of the d. detn., it is possible to compute the % of alc. and H_2O with reasonable accuracy. W. T. H.

Volumetric determination of alcohol. G. CHABOT. *Bull. soc. chim. Belg.* 34, 328-37(1925).—The method is based on the assumption that if 0.5 cc. of beer is suspended in an open vessel within a tightly stoppered flask contg. 25 cc. of 0.175 N $\text{K}_2\text{Cr}_2\text{O}_7$

and 12 cc. of concd. H_2SO_4 , all of the alc. and no other reducing substance can be made to distil into the dichromate by heating at 80° for 1 hr. Then the unreduced dichromate can be titrated iodometrically. The method gives concordant results, which are, however, higher than those obtained by the usual distn.-densimetric method. W. B. P.

Air oxidation of titanous sulfate solution. Vanadous sulfate, a new and powerful reducing agent (RUSSELL) 6.

Ausgewählte Methoden für Schiedsanalysen und kontradiktorisches Arbeiten bei der Untersuchung von Erzen, Metallen und sonstigen Hüttenprodukten. Part II. Berlin: Gesellschaft Deutscher Metallhütten und Bergleute e V. Rm. 10.

VILLARD, A.: **Tableaux d'analyse qualitative des sels par voie humide.** Paris: Masson. 408 pp. Fr. 25. Reviewed in *Tech. Book Review Index* 8, No. 3, 415

Detecting chlorine or other halogens. H. SIMON, LTD., AND H. J. DENHAM. Brit. 237,330, April 22, 1924. Cl, other halogens or CHCl_3 , $\text{C}_2\text{H}_2\text{Cl}_4$ or similar halogen compds. are detected by a green or blue color imparted to the flame of a miner's safety lamp with a Cu gauze in contact with the flame.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

The time factor in the formation of some artificial minerals. A. B. PECK. *J. Geology* 34, 65-70(1926).—The minerals were formed in a Dressler tunnel kiln having a max. temp. of 1460° after continuous operation for 18 months. Silica glass was formed at 500 – 600° (98% SiO_2), probably as the result of pneumatolytic action due to an oxidation of the linings composed of SiC. Hematite pseudomorphs after magnetite were observed in branching arborescent forms, formed at 840° . Cristobalite lithophysae were noted at a temp. above 1460° produced by the oxidation of SiC. Changes were noted at lower temp. than usually recorded in the literature, due to the longer time element. Also the larger size of crystals showed a very rapidly increasing rate as the temp. increased beyond a certain point. Below this point the time factor seemed negligible.

W. F. HUNT

Quartz pseudomorphs. CHARLES PALACHE AND K. K. LANDES. *Am. Mineral.* 10, 405 11(1925).—Two types of pseudomorphs were found at Greenwood, Maine (1) Quartz replacements of cubes truncated by trapezohedrons and (2) incrustations of drusy quartz upon a monoclinic host which was later removed by soln. In the first type the original mineral was analcite or pollucite and in the second heulandite or bertrandite.

C. B. SLAWSON

Skeleton quartz crystals. G. W. BAIN. *Am. Mineral.* 10, 435-41(1925) The skeleton quartz phenocrysts occurring in the rhyolite at Agate Point, Lake Superior are formed of 3 plates intersecting at 60° . B. concludes that these skeletons are growth rather than resorption effects because of the systematic arrangement of the tongues of glass penetrating the crystal. These tongues of glass are parallel to crystal faces and clear quartz extends from the center to the corners showing that the rate of growth is greatest along the crystallographic axes. The rate of etching by HF confirms this conclusion.

C. B. SLAWSON

Veins with fibrous quartz and chlorite from the vicinity of Providence, R. I. GRAGG RICHARDS. *Am. Mineral.* 10, 429-33(1925).—White quartz and yellowish chlorite in all proportions occur as fine fibers nearly normal to the walls of veins 1 to 60 mm. wide. Replacement of chlorite by quartz in all stages from fiber by fiber to "in mass" may be observed. Analysis of the chlorite, purified by sepn. with heavy solns. and the electromagnet, gives: SiO_2 23.8, Al_2O_3 21.8, Fe_2O_3 2.0, FeO 28.2, MgO 10.9, MnO 0.3, H_2O 10.7%. K and Na not detd.

C. B. SLAWSON

Mineralogy of the chrome ore from Etchison, Montgomery Co., Md. E. V. SHANNON. *Am. Mineral.* 11, 16-20(1926).—The chrome ore consists of dark brown fractured mass with a low metallic luster penetrated with numerous small veins of margarite and serpentine. Margarite represents about 10% and serpentine about 30% of the total mass of the ore, the remainder being chrome spinel. The ore carries only 20.56% Cr_2O_3 , which is too low to make it com. available.

C. B. SLAWSON

Some minerals from the Kensington Mica Mine, Montgomery County, Maryland. E. V. SHANNON. *Am. Mineral.* 11, 35-7(1926).—The pegmatite dikes at this mine are

mineralogically different from the other granite pegmatites in the region. They carry such minerals as autunite, gahnite, cleavelandite, spessartite, apatite and beryl. An analysis of spessartite gave: SiO_2 35.76, Al_2O_3 20.72, Fe_2O_3 0.76, CaO 1.22, MgO 0.50, MnO 34.40, FeO 6.66%, which agrees closely with the accepted garnet ratios.

C. B. SLAWSON

Mica schists with piedmontite in the Valli di Lanzo, Alpi Piemontesi. VIRGINIA GENNARO. *Atti accad. Lincei* [6] 2, 508-10(1925).—A description of the mineralogical association of the rock.

E. J. WITZEMANN

Topaz and associated minerals from the Einstein Silver Mine, Madison County, Mo. C. S. ROSS AND E. P. HENDERSON. *Am. Mineral.* 10, 441-3(1925).—Argentiferous galena is found in veins in the Archean granite. The wall rock has been profoundly altered with complete replacement of the feldspar by muscovite and quartz and the introduction of topaz, fluorite, hübnerite and scheelite. Analysis of the topaz gives: SiO_2 32.65, Al_2O_3 54.67, Fe_2O_3 1.78% F not detd., establishing the identity of this mineral for the first time.

C. B. SLAWSON

Some minerals of the Keweenaw copper deposits: pumpellyite, a new mineral; sericite; saponite. CHARLES PALACHE AND HELEN VASSAR. *Am. Mineral.* 10, 412-8(1925).—Pumpellyite occurs as bluish green fibers or narrow plates in the amygdaloidal ores. Its species rank was determined optically and confirmed chemically and showed that it is most closely related to zoisite. It is orthorhombic, + with 2V large, $\rho < \gamma$ strong, $\alpha = 1.698$, $\beta = 1.700$, $\gamma = 1.708$, α and γ colorless, β green, X nearly normal to a perfect basal cleavage, hardness = 5.5, sp. gr. = 3.2. The av. of the 2 analyses given is: SiO_2 36.85, Al_2O_3 23.81, Fe_2O_3 4.38, FeO 3.62, MgO 3.94, CaO 21.62, MnO 0.14, K_2O and Na_2O 0.80, H_2O 5.00%. Saponite is detd. as monoclinic or orthorhombic, —, 2V moderate to small, $\alpha = 1.479$ -90, $\beta = 1.510$ -25, $\gamma = 1.511$ -27, X normal to cleavage and Z parallel to elongation. Analyses of sericite and saponite are given.

C. B. SLAWSON

Notes on dachiardite. HARRY BERMAN. *Am. Mineral.* 10, 421-8(1925).—Crystallographic and optical data gives this mineral species rank. Dachiardite is monoclinic, +, with 2V = 65°, $\alpha = 1.492$, $\beta = 1.496$, $\gamma = 1.500$, X = b, and $Z/\alpha c = 35^\circ$. The axial ratio is 2.4786:1:1.3663, $\beta = 72^\circ 11'$ and the characteristic habit is mimetic twins on (110). It is readily decomposed by HCl and decrepitates and fuses to a white enamel before the blowpipe.

C. B. SLAWSON

Pectolite in the Khibin tundra. E. E. KOSTUILEVA. *Bull. acad. sci. Russie* 19, 383-404(1925).—A description of pectolite deposits and a discussion of pectolite from the chem. and mineralogical standpoint. It may be divided into 2 series: CaSiO_3 with $(\text{Na}, \text{K}, \text{H})_2\text{SiO}_3$ and MnSiO_3 and CaSiO_3 with $(\text{Na}, \text{K}, \text{H})_2\text{SiO}_3$.

J. S. JOFFE

The identity of ectropite and bementite. E. S. LARSEN. *Am. Mineral.* 10, 418-21(1925).—Optical properties and chem. analyses of ectropite, bementite and serpentine show that the first 2 are identical and that they may represent the MnO end of the serpentine series. Bementite is retained as the species name because of priority.

C. B. SLAWSON

Planchéite and shattuckite. ALFRED SCHOEP. *Bull. soc. chim. Belg.* 34, 315-27(1925).—A review and discussion of the properties of these 2 minerals. The formula of planchéite may be written in the form $2\text{SiO}_2 \cdot 2(\text{Cu}, \text{Ca})\text{O} \cdot \text{H}_2\text{O}$, whereas shattuckite is $2\text{SiO}_2 \cdot 2\text{CuO} \cdot \text{H}_2\text{O}$, their close chem. similarity being thus made evident. W. B. P.

Purple muscovite from New Mexico. W. T. SCHALLER AND E. P. HENDERSON. *Am. Mineral.* 11, 5-16(1926).—A reddish purple muscovite which is strongly pleochroic upon the basal section is found in Taos County, New Mexico. The pleochroism is most intense in specimens with the highest Fe and Mn content. The only other published description of a muscovite with a high Fe content is "baddeckite" which is non-pleochroic. An examn. of baddeckite under the microscope shows that it contains 2 component minerals, one of which has the optical properties of thin scales of hematite while the other resembles a clay. By recalculating the original analysis of baddeckite after assigning all the Fe to Fe_2O_3 , it is shown that the remaining material has the composition of the clay, cimolite.

C. B. SLAWSON

A peculiar manganiferous serpentine from Franklin Furnace. E. V. SHANNON AND E. S. LARSEN. *Am. Mineral.* 11, 28-30(1926).—This serpentine is red-brown in color with hardness = 5.5, and resembles massive garnet. Analysis gave: SiO_2 41.32, Al_2O_3 0.65, FeO 1.57, MnO 7.57, ZnO 0.14, MgO 32.58, CaO 0.96, $\text{H}_2\text{O} + 12.44$, $\text{H}_2\text{O} - 0.94\%$. The mineral is optically — with 2V medium, $\alpha = 1.561$, $\beta = 1.567$, $\gamma = 1.568$.

C. B. SLAWSON

Radiated chrysotile from Franklin Furnace, New Jersey. WM. F. FOSHAG. *Am. Mineral.* 11, 38-9(1926).—Examn. of a no. of Franklin Furnace specimens of "wave"

lite" showed that they were chrysotile. The *ns.* were slightly higher than the accepted values and analysis gave: H_2O —2.31, H_2O + 14.51, SiO_2 41.47, Al_2O_3 0.10, FeO 0.90, CaO 0.83, MgO 38.40, MnO 0.71, alkalis 0.42%.

C. B. SLAWSON

The so-called genthite from Webster, North Carolina. C. S. ROSS AND E. V. SHANNON. *Am. Mineral.* 10, 444–5(1925).—This mineral occurs as films or veinlets in a partly altered dunite. It is in a cryst. metacolloidal state with mean $n = 1.510$, optically +, and probably uniaxial. Analysis gives: SiO_2 43.26, Al_2O_3 + Fe_2O_3 1.20, CaO 0.24, MgO 30.00, NiO 4.20, H_2O + 10.54, H_2O — 9.30%. This indicates that the mineral is a nickelliferous variety of deweylite rather than genthite.

C. B. S.

The identity of "lehnerite" and ludlamite. HARRY BERMAN. *Am. Mineral.* 10, 128–9(1925).—The optical properties of "lehnerite" are $\alpha = 1.650$, $\beta = 1.669$, $\gamma = 1.689$, +, $\rho > v$, 2V large. It has perfect basal cleavage, sp. gr. = 3.19, and hardness = 3.5. These properties agree so closely with those of ludlamite that "lehnerite" is considered as a Mn-Mg variety of ludlamite.

C. B. SLAWSON

The identity of gilpinite and johannite. E. S. LARSEN AND HARRY BERMAN. *Am. Mineral.* 11, 1–5(1926).—Detns. of the optical properties of johannite show that gilpinite is identical with it; johannite is retained as the species name because of priority. The optical constns. are triclinic, negative, 2V about 90° , $\alpha = 1.572$, $\beta = 1.595$, $\gamma = 1.614$, $\rho > v$ strong, strongly pleochroic, greenish yellow to canary yellow. Specimens from different localities show a very close agreement in all optical properties. The suggested formula is: $(Cu, Fe, Na_2)O, UO_3, SO_3 \cdot 4H_2O$.

C. B. SLAWSON

The identity of newtonite and alunite. WM. F. FOSHAG. *Am. Mineral.* 11, 33–5(1926).—Analyses of "newtonite" from the original locality gives: SO_3 34.92, SiO_2 0.96, Al_2O_3 38.56, CaO 0.78, MgO 0.30, K_2O 8.23, Na_2O 0.80, H_2O 15.15%. The mean $n = 1.58$. The chem. compn. and the phys. and optical properties indicate that "newtonite" is not a species but is identical with alunite. The analysis given with the original description of newtonite is similar in all respects to that of halloysite, so must have been founded upon an error in connection with the material analyzed.

C. B. SLAWSON

Mineralization of the Platteville-Decorah contact zone in the Twin City region. C. R. STAUFFER. *Bull. Geol. Soc. Am.* 36, 615–22(1925).—The Platteville-Decorah contact has passed through 4 stages of mineralization. The first was soln. of the highly calcareous shells, then followed dolomitization of the remaining Ca. Fe-bearing solns. next deposited pyrite in the open spaces, and later the pyrite coatings were covered by calcite.

W. F. HUNT

Mines and ore deposits of Southern Norway. STEINAR FOSLIE. *Norges Geol. Undersøkelse* No. 126, 89 pages(1925).—On the map accompanying this paper all the mines and ore deposits of Southern Norway, 1407 in all, are collected for the first time. Their extension, importance and geological characteristics are outlined. Predominating at present are pyrite, Cu and Fe ores and these will probably also dominate the future production. The Mo, Ni, Ti, Zn and Ag ores have been mined or are known in such quantities that they may be said to have national economic importance. Pb, As, Au, Cr, Co, Mn, Bi, U and V have been mined to a less extent, but deposits of real importance are not known yet. W, Sb and Pt have been extracted in minute quantities. Sn and Hg are the only economically important metals which have not been found at all in Norway.

C. A. ROBAK

The genetic relations of the deposits of ore in the Krivoi Rog. P. P. PYATNITZKII. *Trans. Inst. Econ. Mineral. and Petrography* (Moscow) 1924, No. 9, 1–55(1924).—A treatise on the genesis of the Fe-ore deposits, a description of the region, its geology, compn. and structure of the cryst. rocks on the Dnieper. P. compares the formations with those of the U. S. in the Great Lakes region. A complete summary in English is given. II. Ferruginous cherts and jaspilite. *Ibid* 1925, No. 17, 1–42.—A critical study of Fe-ore deposits throughout the world in comparison with those in the Krivoi Rog district. P. takes up the formation of Al silicates, their soly. and deposition in the upper layers of the crust, cementation of sandstones and other rocks, SiO_2 content of river and sea waters, consumers of Al silicates, source of Fe, its soly. and deposition in rocks, Fe content of river and sea waters, consumers of Fe in the ocean waters, thickness of yearly deposition of Al silicates, Fe oxides and $CaCO_3$, the problem of change of quantity of SiO_2 , Fe_2O_3 , $CaCO_3$ brought in by the rivers in early geological times and the geological picture of the formation of pre-huronic ferruginous cherts and jaspilite. A good English summary is given.

J. S. JOFFE

The natural iron pigments, their chemical and mineralogical composition and technical properties. I. KURBATOV. *Trans. Inst. Econ. Mineralogy and Petrography* (Moscow) 1925, No. 14, 3–36.—Chem. and mineralogical analyses are given of the Fe-pigments found in various sections of Russia. The process of formation of ochre and

"mummy" (rouge) is as follows: When Fe ore contg. ferrous Fe on the surface or in the faults in the vicinity, is oxidized, some of the Fe oxide goes into a dispersed phase; red "mummy" is formed under such conditions. When ferric Fe is present this dispersion leads to the formation of native red pigments, rich in Fe oxides. The technical properties, mineralogical compn., quantity of staining pigment depend on the original chem. compn. of the ore or rocks, from which the red pigments are formed *in situ*. When the native red pigments have been weathered still more, combined with hydration and dispersion of the oxides of Fe, yellow pigments (ocher) are formed. In the decompn. of pyrite and marcasite "mummy" is formed first and later also ocher. Enrichment of bauxite with the dispersed Fe oxides brings about the formation of red pigments which contain free Al_2O_3 .

J. S. JOFFE

New deposits of uranium and vanadium in the Minusinsk district, State of Eniseisk. S. M. KURBATOV. *Bull. acad. sci. Russie* 19, 315-22(1925).—The minerals found in the district correspond to allophane; in these, concretions of canary-yellow color were found, contg. 20.62% V_2O_5 and 0.36% U_3O_8 .

J. S. JOFFE

Investigations on the salt mass from the waters of the Sosnevskaia factory, Ivanovo-Vosniesensk. V. I. PASTAGANOV AND V. A. ZAITZEV. *Bull. Inst. Polytech. Ivanovo-Vosniesensk* 7, 120-31(1923).—A report of the compn. of a salt body, its geological history and adaptability as a source for use.

J. S. JOFFE

Phosphate ores of U. S. S. R. A. V. KASAKOV. *Trans. Inst. Fertilizers* (Moscow) No. 24, 1-66(1925).—This is a report of the phosphate deposits of Jegoryevsk, Moscow government. It gives the geology of the region, of the phosphate deposits, the phys and chem. characteristics of the phosphatic ores and of the adjacent layers, the methods used in the investigations and resources.

J. S. JOFFE

Certain clays from the productive series near Moscow. N. N. SMIRNOV. *Trans. State Exptl. Inst. of Silicates* (Russian) 1924, No. 15, 1-12.—A study of the clays in the region near Moscow, their geology, composition, genesis and uses.

J. S. JOFFE

Coal bed in the metamorphic terranes south of Limoges. JEAN GANDILLOT. *Compt. rend.* 182, 274-5(1926).—Analysis of the coal showed fixed C 58.23%, volatile matter 29.20, H_2O 1.82, ash 9.85, S 0.40, heating value 6048 cal. The age of the deposit is uncertain because of the absence of fossils.

L. W. RIGGS

Coal deposits of Albania. ERNST NOWACK. *Montan. Rundschau* 18, 69-84 (1926).—Mainly a geological discussion, with many maps and a few coal analyses.

W. B. PLUMMER

The effect of rock flowage on the kerogen of oil shale. F. M. VAN TUYL AND C. O. BLACKBURN. *Bull. Am. Assoc. Petroleum Geol.* 9, 158-64(1925).—It has frequently been reported that the kerogen of oil shale could be converted to petroleum at elevated pressures. Recent exptl. work by V. and B. on typical shales from Elko, Nevada, and Grand Valley, Colorado, to det. quantitatively the amt. of oil produced when these shales were subjected to rock flowage at ordinary temps. disclosed the fact that no free oil was formed under such conditions. In view of the results obtained there is reason for doubting the common conception that the kerogen of oil shales represents a stage in the transformation of org. material to petroleum.

C. L. C

A proposed classification of igneous rocks. E. T. HODGE. *Univ. of Oregon Publications* 2 (No. 7), 72 pp.(1924).—Previous classifications are described, also an ideal classification which is planned to cover 18 objectives. It is based on modal minerals which are expressed in actual percentages, and uses a diagram consisting of a circle divided into 2 pairs of equal sectors to show the classes, each sector is divided into 19 smaller sectors by radial lines to show the orders. Six concentric circles are equally spaced inside the original circle to show the rangs. By means of this chart a rock classified either chemically or mineralogically will arrive at the same compartment of the chart.

L. W. RIGGS

The specific heats of rocks. TOKIHARU OKAYA. *Japan. J. Astron. Geophysics* 3, 45-80(1925).—A list of the sp. heats and a petrographic description of 73 Japanese rocks belonging to the andesitic, tuffic, metamorphic and granitoid classes is given. The sp. heat varies considerably from sample to sample in the same rock and is rarely greater than 0.30 or less than 0.10. In general, for andesitic rocks of the Na group it lies between 0.28 and 0.24; for rocks of the K group, 0.20 and 0.14. In the tuffic class, that of Na rocks is between 0.27 and 0.23; of K rocks, 0.20 and 0.18; of metalloid rocks, below 0.16. The sp. heat of cryst. limestone is between 0.19 and 0.25; of granite, 0.25 and 0.18; and of saccharoid marble, greater than 0.26.

D. S. VILLARS

Concerning "evidence of liquid immiscibility in a silicate magma, Agate Point, Ontario." N. L. BOWEN. *J. Geology* 34, 71-3(1926).—Globular inclusions differing in color from the main mass do not constitute sufficient evidence for liquid immiscibility.

bility. The same effect might have been produced by hydration and oxidation by permeating solns. W. F. HUNT

Spectrum analysis of the flames from the Santorin volcano. (Eruption of 1925.) G. GEORGALAS and N. LIATSIKAS. *Compt. rend.* 182, 148-50(1926). Orange-colored flames 15 to 20 m. high were observed, also yellowish green, bluish green or blue flames which seldom exceeded 1 m. in height. The spectroscope showed the presence of the blue H-ray ($\lambda = 486.1$), the Na(D) ray, Cl-blue rays ($\lambda = 481, 479.4, 489.7, 490.3$) and the N-blue band. Rays of Fe and O were probably present. From a fumerole there were exhaled H_2O , HCl, CO_2 and small quantities of SO_2 . In the principal cloud of the volcano the SO_2 was in sufficient quantity to make the air irrespirable. L. W. R.

The paragenesis of the granite pegmatites of central Maine. K. K. LANDES. *Am. Mineral.* 10, 355-405(1925).—The pegmatites show 5 successive stages of mineralization: (1) coarse granitic pegmatite formed by mass crystn.; (2) the development of large cavities by the solvent action of hydrothermal solns. and the deposition in these cavities of Si-Na-Cs-Cb-Ta-Sn minerals; (3) the partial soln. of minerals previously formed and the deposition of Li-Mn- PO_4 minerals; (4) hydrothermal activity ceases with a Li-Si phase; (5) the development of secondary minerals by ground-water activity. L. believes that the cavities of the Maine pegmatites are largely due to soln., though they may follow the trend of primary cavities produced in the igneous magma by shrinking or gas bubbles. C. B. SLAWSON

Evolution of the mineralogical composition of the skeletons of organisms. Y. V. SAMOILOV. *Trans. Inst. Econ. Mineralogy and Petrography* (Moscow) 1923, No. 4, 1-16.—The author traces the mechanism of the mineralization of the skeletons of certain lower animals and discusses the question of the role of organisms as geological agents in the formation of mineral substances. The accumulation of different chem. substances by organisms is discussed. J. S. JOFFE

Deposits of silica of organic origin. Y. V. SAMOILOV and E. V. ROZHKOVA. *Trans. Inst. Econ. Mineralogy and Petrography* (Moscow) 1925, No. 18, 1-65.—The theories of the role of organisms in forming siliceous deposits are analyzed. Diatomaceous ooze, from the lake Baikal was subjected to chem., mech. and microscopic examn. The soly. of the frustules of diatoms in 5% soda was considerable (63.6 to 72.8% SiO_2). Spicules from the sponge *Geodia baretii* were analyzed. Chem. and mineralogical investigations were made on tripolite from various localities of Russia. Samples of "gaize" of early Tertiary age were examd., and it was found that there are several types of gaize, varying in chem. compn. and phys. properties. Detailed descriptions with micrographs of these are given. As a result of the relatively high soly. of the hydrogel of silica the gaize gradually alters its characteristics and merges into varieties of chert. The authors consider the origin of these rocks as a result of biochem. processes and regard them as *silicobioliths*. The literature on the subject is thoroughly reviewed and criticized. An English résumé is given. J. S. JOFFE

The occurrence of lower Tertiary gaize in European Russia. A. N. SEMICHATOV. *Trans. Inst. Econ. Mineralogy and Petrography* (Moscow) 1925, No. 18, 68-73.—This article supplements the discussion of Samoilov and Rozhkova (preceding abstr.). J. S. JOFFE

The use of a lead plate for finishing microscopic rock sections. A. SHUBNIKOV. *Trans. Inst. Econ. Mineral. and Petrography* (Moscow) 1924, No. 10, 25-6.—Lead plates have the advantages over glass plates of slower wear, the possibility of using one single grade of emery in finishing a section, the possibility of using higher pressure and safety against casual larger sized grains of emery, which imbed in the lead. J. S. JOFFE

Bibliography of the mineral wealth of China. III. C. Y. WANG. *J. Assoc. Chinese Am. Eng.* 6, No. 5, 37-53(1925).—For the period 1918 to 1924. W. H. A.

Chemical analysis of Feng Huang iron ore (WANG) 9. The loess of China (BARBOUR) 15. A support for the condensation of sublimes (BRALY) 1. Analyses of gases from rocks by microchemical methods (METTA) 7.

D. J. DEMOREST, ROBERT S. WILLIAMS

The relation between metallurgy and atomic structure. P. D. FOOTE. *Trans. Am. Inst. of Min. & Met. Eng.* 1926, (advance proof), 29 pp.—An address reviewing the quantum theory of atomic structure as it applies at the present to the solid state and to metallurgy. Bibliography. ALBERT THOMAS FELLOWS

Secondary metals in 1924. J. P. DUNLOP. U. S. Geol. Survey, *Mineral Resources of U. S.* 1924, Part I, 119-39 (preprint No. 12, published Feb. 11, 1926). E. H.

Recording alkalinity or acidity of flotation pulp. D. WELGE. *Eng. Mining J. Press* 121, 409 (1926).—The general arrangement of electrodes and ammeter used in detg. the cond. of a mill pulp is shown. Soda is added periodically to the primary cells to secure the desired flotation results and the correct amt. is checked by detg. the cond. of the soln. The size of the plates, and the distance between them are so adjusted that the ammeter registers at about the center of the ammeter scale. W. H. BOYNTON

Selective flotation at Bauer, Utah. EDWARD HODGES ROBIE. *Eng. Mining J. Press* 121, 405-7 (1926).—Flow sheets for crushing, fine-grinding and classification, and Pb and Zn flotation of Pb-Zn ores are shown. The manner of handling the circulating load in the Pb circuit is impressive. The concentrate from the flotation cell fed with middling, together with Pb tailings, is returned to the ball-mill classifier. 90% of the crushed ore passes a 200-mesh screen. W. H. BOYNTON

Effect of cyanogen compounds on the flotability of pure sulfide minerals. E. L. TUCKER, J. F. GATES and R. E. HEAD. *Mining Met. J.* 126-9 (1926).—A table has been established of normal relative flotability for chalcopyrite, chalcocite, bornite and pyrite in distd. water under standard conditions. Cyanide in conjunction with lime produces a more depressing action on pyrite than lime alone. High lime alky. depresses markedly the flotability of chalcocite necessitating close alky. control for elimination of pyrite. The exptl. results indicate a feasible method for the elimination of pyrite during Cu concn. A microscopic study is made of surface effects produced on pyrite by contact with NaCN or other reagents in a flotation cell. W. H. B.

Classification on the Witwatersrand. B. R. BATES. *Trans. Am. Inst. Mining Met. Eng.* No. 1560-B, 11 pp. (Feb., 1926).—The results of tests with cones, straight type and bowl classifiers are outlined and the importance of quality of feed and classifier speed is pointed out. The use of "corduroy" tables and cyanidation on ore crushed to 5-10% plus 60-mesh with a corresponding total of 75-80% minus 90-mesh results in satisfactory recovery. The use of the bowl type as a concentrator is being considered. W. H. BOYNTON

Precipitation efficiency of zinc dust in cyanide solutions. ROBERT LIPSOE. *Trans. Am. Inst. Mining Eng.* 71, 1061-5 (1925).—The presence of Pb is not of importance. There is a distinct relation between pptn. efficiency and fineness; the effect generally can be estd. by examp. the size of metallic particles. H. C. PARISH

Treatment of the telluride-bearing gold ores of the Wright-Hargreaves Mines, Ltd. W. A. MUELLER, J. E. GRANT and C. L. HEATH. *Trans. Am. Inst. Mining Met. Eng.* No. 1549-D, 12 pp. (Feb., 1926).—Au occurring as tellurides is but slightly acted upon by the ordinary cyanide treatment. Flotation of the tailings from the regular cyanidation process, taken directly from the Oliver filters, results in a good sepn. Flotation is materially aided by finer grinding and cannot replace it. Results are tabulated from tests using as feed the pulp pumped from the Dorr classifiers. Straight cyanide treatment fails on the resulting concentrate. Roasting of the concentrate renders the Au sol. A flow sheet of the present mill practice and one rearranged for treating roasted concentrates in circuit are shown. The bromocyanide process shows rapid action and when uniform grade of flotation concentrate is obtained should give even better results than at present. Exptl. data are included. W. H. BOYNTON

Lead in 1924 (smelter report). C. E. SIEBENTHAL and A. STOLL. U. S. Geol. Survey, *Mineral Resources of U. S.* 1924, Part I, 149-64 (preprint No. 13, published Feb. 26, 1926). E. H.

The Durango lead smelter and sulfating plant. E. H. ROBIE. *Eng. Mining J. Press* 121, 288-90 (1926).—A description of operations. A. BUTTS

High zinc in lead blast-furnace slags. F. E. BEASLEY. *Trans. Am. Inst. Mining Met. Eng.* 71, 919-28 (1925).—The ZnO content of Pb blast-furnace slags was increased from 13.5 to 20.0% and the FeO content reduced from 33.5 to 25.6% by the addition of 10 to 12% granulated slag to the roaster charge and improved conditions of the crushing, mixing and roasting of the constituents of the sinter. H. C. PARISH

A zinc-distillation furnace with vertical. ROTT. *Feuerungstechnik* 14, 85-6(1926).—The furnace is oval, 70 by 150 cm. high. They are charged from above and discharged into a tank beneath; thus they save a great deal of labor. They may be made by machine; the method of condensing in a sort of side-neck and is tapped out at the bottom. The method of heating is described.

The theoretical basis for metallurgical zinc production. ERNST JANECKE. *Metall. u. Erz* 22, 316-21(1925).—A diagrammatic presentation of the relations between C, Zn, ZnO, CO and CO₂ at different temp. during Zn distn.

Redistillation of zinc. KURT STOCK. *Trans. Am. Inst. Met. Eng.* 71, 897-918(1925).—A review of redistn. methods in use since this method of producing pure Zn was put into practice.

The outlook for aluminum. R. J. ANDERSON. *Mining Mag.* 34, 137-47(1926).

Studies in copper slagging. F. FREIH. V. CZEDIK. *Metall. u. Erz* 22, 175-9(1925).—The relation between the Cu content of the reverberatory mat and slag in the Mansfeld process was studied in special tests and over a long period of normal operation. The mat generally ranged from 70 to 74.4% Cu and the slag from 2.2 to 4.0% Cu. The Cu content of the slag may increase greatly if the concn. in the mat exceeds 75%.

Utilization of chlorine in recovery of tin and tin salts from tin-plate scrap. C. L. MANTELL. *Trans. Am. Electrochem. Soc.* 49 (preprint) (1926).—In detinning with Cl all humidity must be excluded, to prevent corrosive action of Cl on the Fe. The scrap must also be free of org. substances, and the process cannot be used for unclean scrap. Provision must be made for keeping the temp. of the reaction chamber below 38°, otherwise the Fe will be attacked. In the Goldschmidt process, the material is placed in baskets in large cylindrical containers, and dry Cl is introduced under a pressure of 3.7 atm. at 0°, or 7.6 atm. at 25°. After the reaction is complete, the gases are drawn off along with any volatilized SnCl₄, and the detinned scrap is washed and dried. In the method of Von Schutz, a dry mixt. of Cl and air is drawn through the scrap by suction. Dubois and Kaufman employ Cl in a solvent such as CCl₄. The Sn salts and solvent are recovered by addn. of H₂O or steam, or the soln. of the Sn salts in CCl₄ may be electrolyzed. Other processes are briefly described. In the Cl process the plant cost will vary from \$15 to \$20 per ton of scrap handled for a yearly capacity of 1500 tons to \$8 to \$10 per ton of scrap for a yearly capacity of 10,000 tons. Cl consumption will be approx. 80-100 lb. per ton of Sn plate of the quality used in the manuf. of Sn cans.

Chemical analysis of Feng Huang iron ore. C. WANG. *Science (China)* 10, 951-7(1925).—Forty analyses of this important deposit av. 47.8% Fe. The S is high; working of this ore is declared impracticable.

Desulfurization of spathic iron ore during roasting. A. WEYEL. *Stahl u. Eisen* 45, 1273-4(1925).—Spathic Fe ore from Siegerland, contg. very variable amts. of S, due to its admixt. with Cu and Fe pyrites, loses most of this S on roasting. Samples of the ore having a S content of 2.56-2.64% were ground to particles less than 2 mm. and roasted in an electrically heated oven at temps. of 700°, 800° and 900°. The amt. of S burnt off (as dioxide and trioxide) depends on the temp. and on the time of roasting, but particularly on the former, 800-900° being found most effective. Roasting for 6 hrs. at 800° reduced the S to 0.44% and for 2 hrs. at 900° to 0.48%. The rate of desulfurization is rapid at first, but falls off with decreasing S content. Because of the varying distribution of temp. and other factors, similar quant. results may not hold for large-scale practice. A smaller degree of desulfurization takes place when the hot roasted ore is quenched with water. This is due to the washing out of MnSO₄ formed during the roasting. Five g. of ore roasted at 840° had its S content reduced from 0.564 to 0.055% on washing with 1200 cc. of hot water. The washings contained no metal except Mn. Complete removal of the residual S in this way would require too much water for large-scale work. MnSO₄, however, is completely decomposed at 900°, and the amt. of S left in well-roasted Siegerland spathic Fe ore may be ignored with reference to the limestone required in the smelting furnace.

[Spathic] ore roasting. N. FLEISSNER. *Stahl u. Eisen* 45, 1373-9(1925).—Spathic Fe ore was heated in streams of various gases, and the amts. of CO₂ given off in a given time were measured as a function of the temp. The temp. necessary for the decompn. of the Fe carbonate fell as the partial pressure of the CO₂ was diminished, the effect depending on the nature of the gas used in the following order—water vapor, air, N, CO₂. Decreasing the grain size of the ore increased the rate of decompn. The quicker

results obtained with finely divided material suggested a modification of roasting furnace design and led F. to suggest that the blast furnace may be superseded. The heat set free by the oxidation of FeO to Fe_2O_3 during the roasting process should be made use of in practice to diminish the external heat applied. The method of roasting described may be applied to ores contg. large quantities of FeO , as this is readily reducible if porous. Moreover, contamination of the ore by the ash of the fuel and local heating and formation of lumps are avoided.

Blast-furnace practice in Alabama. H. E. MUSSEY. *Trans. Am. Inst. Mining Met. Eng.* **71**, 436-52(1925).—A brief summary of existing practice in this district Southern practice tends to carry higher stove temp. than Northern plants as well as a higher blast vol. for a given size of stack. It is thought that still higher stove temp will be maintained with the more thorough cleaning of the gas and adequate stove capacity. This will result in lower fuel consumption and increased production.

H. C. PARISH

Effect of sulfur on blast-furnace processes. T. L. JOSEPH. *Trans. Am. Inst. Mining Met. Eng.* **71**, 453-69(1925).—In charcoal furnaces, about $\frac{2}{3}$ of the S in the materials comes from the charcoal, and about $\frac{1}{3}$ of the total S charged enters the metals. In coke furnaces about 92% of the S comes from coke, but only about 5% enters the metal. Slag carried off 86.7%. The elimination of S, therefore, in coke furnaces is difficult as the allowable % entering the metal is so small. In 1921 S in coke cost the country's resources 3,000,000 tons of fuel. The possibilities of desulfurization by steam are being studied.

H. C. PARISH

The blowing-in methods with a water-jacketed furnace. V. P. SMIRNOV. *J. Russ. Met. Soc.* **1925**, Pt. I, 297-303.—Expts. on the charging of water-jacketed furnaces so as to give max. efficiency of the blowing-in process are described. The ratios of wood, coke and other materials are worked out.

J. S. JOFFE

Economic significance of cyanide accumulation in the blast furnace. R. FRANCHOT. *Trans. Am. Inst. Mining Met. Eng.*, July, 1925, (advance copy) 14 pp.—The reactions occurring in the blast furnace, particularly those involving the oxidation of C and reduction of Fe oxide, are discussed in relation to furnace efficiency. The 2 to 1 ratio of CO to CO_2 in the gas at the top of the furnace is not necessary, since it has been experimentally demonstrated that FeO can be reduced to Fe with a gas contg. more than 50% CO_2 and less than 50% CO , and that hematite and magnetite are reduced at all furnace temps. to FeO by gases contg. much more than 50% CO_2 . The greatest loss in the furnace is that about $\frac{2}{3}$ of the coke C is not converted from CO to CO_2 . That about twice as much coke is required to produce 1 ton of Fe as indicated by heat-developing and heat-absorbing values is attributed to the heat required to vaporize, as cyanide, accumulated alkalis. About 30% of the coke burned in the hearth appears to be applied to cyanide vaporization. Measurements of cyanide concn. in hearth gases have shown this to reach as much as 4% by vol. or 9 lb. of KCN per 1000 cu. ft.

B. C. A.

Temperature and analysis of gases in the throat of a recently constructed blast furnace. H. LENT. *Stahl u. Eisen* **45**, 1149-52(1925). Continuous records were taken of the temp. and compn. of the gases at the middle and circumference of the throat of a furnace having an av. output of 774 tons per day. The temp. in the downcomer, the temp., pressure and quantity of the blast, and the depth of the charge were also recorded. Particulars are given of the compn. and grading of the charge. Contrary to what is supposed from an examn. of the flames, the temp. was higher in the middle of the throat than at the periphery, especially when "chimneys" tended to form in the middle of the furnace. An unsuitable ratio between the fine ore and lump ore charged, caused the latter to roll to the center, thus forming a path of lower resistance for the gas current. The gases from the middle of the throat were 2-3% lower in CO_2 and 3-4% higher in CO . The changes in the gas analysis during tapping are recorded. At the moment of plugging the tap hole the gases were extraordinarily rich and contained 8-9% of H compared with a normal content of 1.5%. The H was formed by the reaction of chemically combined water or ordinary moisture with CO_2 and CO , and may explain some of the difficulty in keeping furnaces damped. A zone of indirect reduction was present in the upper part of the shaft. Uniformity in size of ore lumps resulted in a smaller coke consumption.

B. C. A.

Desulfurization and reduction in cupola furnaces. A. WAGNER. *Stahl u. Eisen* **45**, 1202-5(1925).—A crit. comparison is made of the results obtained with various manganiferous desulfurizing media in cupola practice. The effect is greater the more reducible the Mn oxide used. To det. the possible degree of reduction W. used ferro-manganese blast-furnace slag, which had a higher S content than pure Mn ore, but this

did not affect its desulfurizing power. Expts. were made in 2 cupolas of 480 mm. and 800 mm. diam., resp., with a charge coke percentage of 8.5–9.0. The S in the Fe was reduced 18–36% by the use of the ferromanganese slag, the favorable effect being due to the easy reduction of its MnO content. The use of a forehearth had no effect on the desulfurizing action and the basicity of the slag, but appeared to favor Mn reduction in the furnace. The Mn reduction was independent of the basicity of the slag and increased with the Mn concn. in the burden. The ferromanganese slag raised the Mn content of the Fe, but the Fe loss was greater. A high Mn content in the cast Fe did not appreciably increase the desulfurization. The higher MnO content of the slag protected the Fe from taking up S from the gases, and exerted a greater desulfurizing effect than limestone on charges with high S content. Desulfurization was, however, more certain when fluorspar was used. B. C. A.

New Wüst furnace for refining high-quality cast iron. T. KLINGENSTEIN. *Stahl u. Eisen* 45, 1476–8(1925).—In the production of high-quality pearlitic cast Fe it is difficult to hold the C low and regular in the cupola furnace. Although the C content can be reduced it is at the expense of the temp. of the molten Fe, and when tapping small quantities the compn. is irregular. The Wüst oil-fired flame cupola furnace is designed to overcome these difficulties. The oil burner is at one end and the charging shaft at the other. The flame licks the bath and meets the bottom end of the charge column. The exhaust gases are used to preheat the blast to 400–600°. The fuel is tar oil; 2% of lime is added to the charge and no coke is used. With an output of 1020–1125 kg. per hr. the total oil consumption was 8–10%, the Fe being tapped at 1500–1600°. The S content is low, and the finely divided graphite is more like temper C. B. C. A.

The calculation of charges of the ore scrap-iron open hearth (Martin) process. C. I. SHARASHKIN. *Trans. Inst. Exp. Silicates (Russian)* 1923, No. 6, 1–31.—This is a discussion of the metallurgical principles involved in the Martin process. Many analytical data on various charges with a diagram of the changes taking place are given. J. S. JOFFE

Making rimmed steel. CARL PIERCE. *Trans. Am. Inst. Mining Met. Eng.*, Feb., 1926, No. 1563-C, 11 pp.—P. deals with the manuf. of rimming steel by the open-hearth process, and with lower-C steels, such as sheet bar, rivet stock, skelp, etc. Materials of known compn. must be used, a satisfactory mix made, and enough pig iron charged to insure heats that will not melt soft. Working and tapping temps., proper shaping of the slag and slow pour are essential. The steel must contain sufficient CO to produce the rimming effect. The finished steel should preferably contain only a trace of Si, and for soft steel 0.08–0.10% C and 0.30–0.35% Mn. W. H. B.

Elimination of metalloids in the basic open-hearth process. J. L. KEATS AND C. H. HERRY, JR. *Trans. Am. Inst. Mining Met. Eng.*, Feb., 1926, No. 1550-C, 28 pp.—Very complete exptl. data obtained in a 100-ton (90,909 kg.) stationary furnace are given. The charge consisted of scrap, pig iron, dolomite, ore and spar. Accurate record was kept of the wts., the temps., sampling of metal and slag, and the rate of elimination of C, Mn, P and S. Wide variations in compn. of the bath, from door to door, occur right after ore addns., while the compn. becomes uniform under finishing conditions. It is probable that the gas given off from the decompn. of the limestone desulfurizes the bath. Erosion of the furnace lining is dependent, for a given amt. of slag, primarily on the SiO₂ content and the fluidity of the slag. The rate of soln. of lime from the limestone into the slag is dependent, under the same conditions, on the fluidity of the slag and on its Fe oxide and SiO₂ content. The rate of elimination of metalloids is mainly controlled by the fluidity of the slag. Numerous tables and curves are included. W. H. BOYNTON

The Krupp nitrogen process for case hardening. AD. FRY. *Krupp Monatsh.* 7, 17(1926).—Detailed description profusely illustrated. C. G. F.

Temper carbon and iron graphite as identical forms of carbon. A. LISSNER AND R. HORNBY. *Stahl u. Eisen* 45, 1297–301(1925).—The chem. behavior of graphite from gray Fe and temper C pptd. during the annealing of white Fe has been compared, and the conclusion is drawn that the 2 forms of C are identical. Both give graphitic acids of the same compn.; neither is attacked by fused Na₂SO₄, and both resist the action of HNO₃ and of a mixt. of HNO₃ and H₂SO₄. Because of its more finely divided condition, temper C ignites at a lower temp. than Fe graphite, but both have the same heat of combustion. B. C. A.

Austenite and austenitic steels. J. A. MATHEWS. *Trans. Am. Inst. Mining Met. Eng.* 71, 568–96(1925).—See C. A. 19, 3457. G. F. C.

Inspecting and testing automobile axles. R. L. ROLF. *Blast Furnace and Steel Plant* 13, 386–91, 418(1925).—A general discussion of the chem., mech., microscopic,

and deep-etching methods of testing axes. The usefulness of the results obtained is emphasized, and the article is well illustrated by photomicrographs and photographs of machines, etc. G. F. C.

Finishing melting temperatures of simple ingot steels. H. D. HIBBARD. *Trans. Am. Inst. Mining Met. Eng.* 71, 476-506 (1925).—The compn., casting temp., and rate of teeming det. the quality of plain C steel. There is an ideal pouring temp. for any given ingot of steel, although a different temp. may give serviceable metal. Casting steel too hot causes concn. of impurities along grain boundaries and cracking during hot-working. The effects of Mn and Si on the fusion temp. are negligible, but the tapping temp. becomes lower as the C content is raised, being 1615° with 0.1% C, and 1475° with 1.5% C, if no alloys are melted in the ladle, and teeming is not delayed. A table of tapping and teeming temps. for steels with various C contents is given. Variations of even 10° affect the quality somewhat. The hottest steel in the ladle is at the top, and is teemed last; hence there is little change of temp. during teeming. Pyrometers are not necessary in steel melting, for skilled melters judge the temp. accurately in other ways. The best casting temp. is generally the lowest possible without leaving too much solid steel in the ladle. Caspersen's results published in 1882 are discussed, but are not applicable to present American practice. Pure killed steel of over 0.1% C may be cast very hot without injury. This is common European practice, using small nozzles. Casting effervescing steel too hot impairs the effervescence, so that some gas, probably H, is not removed and causes skin holes. At lower temp. the steel dissolves less gas, so that when cast the H does not sep. until several in. of sound steel have solidified around the sides of the mold. The failure of very hot steel to effervesce properly may be due to a decompn. of CO by Mn at the abnormally high temp. In discussion, A. Sauveur stated that a high teeming temp. produced coarser dendrites only because the mold became hotter, and did not necessarily injure the steel. H. Stern said no steel should contain blowholes, questioned the presence of H in them, and denied the power of Mn to reduce CO. G. V. Luerssen presented the temp. of skull formation for a series of steels, the values being 9° to 28° below the author's ideal teeming temp. The skull temp. was about 10° above the Fe-C liquidus. Various opinions were expressed regarding the value of optical pyrometers in open-hearth work. L. F. Reinartz defended the use of effervescing steel. H. Le Chatelier stated that the tapping temp. of one heat may vary 50°, but the temp. in the ladle is more uniform and more important. The melting temp. may affect the size of the solid dendrites. W. J. Priestley reported tapping and teeming temps. somewhat lower than the author's but showing the same variation with C content. Molten steel should not be hotter than necessary to flux out the non-metallic inclusions, on account of absorption of gas at higher temp. H. W. Gillett quoted some measurements by Popp of German tapping and teeming temps. that were 30° to 80° higher than the author's. I. A. Billiar reported temps. of 0.48% C and 0.70% C heats that agreed with the author's in tapping, but were lower in teeming. Differences of 28° in casting temp. are negligible, other variations in practice being much more important. W. P. Barba considered that the proper pouring temp. depended on so many factors that no definite value could be fixed. J. Strauss questioned any effect of 10° variations in casting temp., and doubted that casting too hot was ever truly harmless. Hot tapping, cooler teeming and rapid solidification were advocated. H. H. Smith favored the practical test for fluidity. The author in reply emphasized the usefulness of effervescing steel for boiler plate, high-finished sheets, and welded tubes. G. F. C.

An examination into the causes of the failure of steel rails. E. A. DANCSTER. *Ind. Chemist* 1, 441-8 (1925).—A record of the make, years of service and traffic carried has been kept for a number of fractured rails. Photographs of sections deep-etched with H₂SO₄ show most failures are due to flaws from pipes in ingot. When sound rails fail it is nearly always at the first fish-bolt hole at the leading end. The wearing qualities increase about with the square of the C content between 0.30 and 0.55%. Small grained, ductile metal is desirable. E. L. CHAPPELL

Fatigue failures in steel. F. W. ROWE. *Metal Ind. (London)* 28, 157-9, 185-6 (1926); cf. C. A. 20, 1203.—The fatigue strength is independent of the rate of alternation of the stress. Hollow forgings have good fatigue resistance, are readily heat-treated, and are free from axial defects. Several fatigue failures are described and illustrated. A soft steel shaft with too coarse structure and low yield point failed because the bearings were out of line. Its endurance limit was found to be above the yield point in tension. A gear pinion whose teeth broke in service was found to have been badly machined, and not well heat-treated, having a very coarse grain. A Diesel engine shaft failed too soon on account of poor structure, but the design also was at fault.

The periodicity of the vibrations of a shaft should not synchronize with the pulsations of the engine. G. F. C.

Factors other than dissolved oxygen influencing the corrosion of iron pipes. J. R. BAYLIS. *Ind. Eng. Chem.* 18, 370-80(1926).—The max. iron concns. reached in natural waters contg. CO_2 and Ca salts are much less than the theoretical soly. of $\text{Fe}(\text{OH})_3$. Data on the soly. of FeCO_3 in the presence of CaCO_3 are given. Continuation of corrosion under rust layers depends on the diffusion of sol. iron chlorides and sulfates. Pitting occurs under breaks in an impervious rust membrane. Some iron oxides are magnetic and cling to the metal surface. E. L. CHAPPELL

Corrosion of an ancient tin specimen. C. O. BANNISTER. *J. Inst. Metals* 1926, (advance copy), 2 pp.—Ancient tin articles are seldom found, the metal being unstable below 18° . A medieval English scabbard was 99.98 tin covered by 2.5 mm. of adherent stannic and hydrated stannous oxide. There was little loss in wt. on heating, 5.1% water being driven off, and 4.51% O absorbed. E. L. CHAPPELL

Snead electric heat treating and annealing process. C. C. WAITE. *Metal Industry* (N. Y.) 23, 441-3(1925).—A description with photographs of a direct elec. heat treatment method for tubes, rods and strip. The process consists of passing an elec. current through the mass of the work, the resulting heat being due to its own elec. resistance; the temp. is detd. and controlled by expansion. The application to admiralty brass condenser tubes is detailed. W. A. MUDGE

Eutectic patterns in metallic alloys. C. H. GREEN. *Trans. Am. Inst. Mining Met. Eng.* 71, 651-68(1925).—Excellent photomicrographs of 16 eutectics are presented. In most instances some primary crystals were obtained, as a result of segregation or supercooling of the melt. Portevin's classification (cf. C. A. 17, 1940) is quoted and illustrated by examples, which are discussed. A revised classification is suggested, as follows: Type 1, regular crystals. Type 2, dendrites or skeleton crystals, Bi-Pb, Bi-Sn, Pb-Te. Type 3, colonies or complex grains, Cd-Sn, Cd-Zn, Mg-Sn, Pb-Sn, Al-Zn, etc. Type 4, conical arrangement, Sn-Zn, Sb-Te, Bi-Te. In discussion, C. Benedicks explained the structure of the Cd-Zn and white-cast-Fe eutectic as due to the fact that the fine part froze first and quickly, and the liberated heat of solidification made the coarser part freeze more slowly. G. E. Dalbey described a special habbitt of unusually fine and uniform structure. G. F. C.

Etching aluminum and its alloys for macroscopic and microscopic examination. F. B. FLICK. *Trans. Am. Inst. Mining Met. Eng.* 71, 816-27(1925).—Solns. of NaOH or HF are not always satisfactory for showing the grain size of Al alloys, as tarnished surfaces may be obtained. HF in alc., followed by concd. HCl, has given better results. A soln. of 10 cc. concd. HF and 15 cc. concd. HCl in 90 cc. water was very satisfactory. The specimen is first cleaned with alc. Etching takes 30 to 90 sec. If a black coating is formed by Cu in the alloy, it is removed by concd. HNO_3 . Illustrations show excellent results at magnifications up to 10 diam. The reagent is also suitable for microscopic etching. S. Daniels found it satisfactory and very rapid, 5 sec. etching being sufficient for Al contg. 4% Cu, 2% Ni and 1.5% Mg. G. F. C.

The development of the process of thermal improvement of technical alloys of aluminum. P. ASSMANN. *Metall u. Erz* 22, 506-11(1925).—A review, referring especially to the effect of Si, Mg and Li upon Al alloys. C. G. KING

Casting and heat treatment of some aluminum-copper-magnesium alloys. SAMUEL DANIELS, A. J. LYON AND J. B. JOHNSON. *Trans. Am. Inst. Mining Met. Eng.* 71, 864-88(1925); cf. C. A. 19, 1844.—D. Hanson and M. L. V. Gavler in discussion stated that heat-treated sand castings of Al alloys with 4% Cu showed over 5% elongation, instead of 1.5% as found by the authors. The alloy showing the best combination of strength and ductility contained amts. of Cu and Mg_2Si close to the limit of solid soly. at high temp. The alloys should be quenched from the temp. giving max. supersatn. of the solid soln. There is a best aging temp. and time for each alloy. The elongation of duralumin is reduced by aging at 200° for over 2 hrs. The "Y" alloy contg. 4% Cu, 2% Ni, and 1.5% Mg is stable at 167° . Chill castings contg. 4 to 5% Cu are improved in strength and ductility by annealing for 2 days at 500° and cooling in air. Aging at room temp. is largely due to Mg_2Si , and the effect of CuAl_2 is greater at higher temp. G. F. C.

Bronze welding cast iron pipe. H. Y. CARSON. *Acetylene J.* 27, 429-35(1926).—Results of various tests and proper methods of welding are set forth in detail. W. B. PLUMMER

The effect of heat of bronze welding on cast iron pipes. ARTHUR R. LYTLE. *Acetylene J.* 27, 325-37(1926).—A discussion with 35 photomicrographs. W. B. P.

Welding steel tubing and sheet with chromium-molybdenum welding wire. S. T.

SISCO AND H. W. BOULTON. *Acetylene J.* 27, 377-483, 410-4 (1926).—In welding Cr-Mo steel seamless tubing or Cr-V sheet steel, a Cr-Mo welding wire (0.28% C, 0.61% Mn, 1.14% Cr, 0.95% Mo) gives a more uniform and generally desirable weld than plain low-C wire. In welding Cr-Mo tubing to plain steel tubing, plain steel welding wire should be used. Welded Cr-Mo tubing has a soft area about the weld, due to local annealing, which should be removed by heat treatment. Detailed results of strength tests on welded tubes and many photomicrographs of welds are given. The effects of heat treatment after welding are discussed in detail. W. B. PLUMMER

The effect of rolling on the crystal structure of Al (OWEN, PRESTON) 2. Apparatus for treating roasted ore with liquids (Brit. pat. 237,571) 1. Filters for metallurgical solutions (U. S. pat. 1,574,556-7-8) 1. Lacquering, drying and "blueing" apparatus (Brit. pat. 237,581) 1.

GUILLET, L. and PORTEVIN, ALBERT: *Précis de metallographie microscopique et de macrographie*. 2nd Ed. revised. Paris: Dunod. 340 pp. Fr. 65. Reviewed in *J. Inst. Metals* 33, 617 (1925).

MUNDEY, A. H.: *Tin and the Tin Industry*. The Metal History, Character and Application. London: Sir Isaac Pitman & Sons, Ltd. 3s.

Froth flotation separation of ore constituents. R. ELLIS. U. S. reissue 16,270, March 2. See original pat. No. 1,425,186 (*C. A.* 16, 3300).

Filtering and thickening apparatus for treating ore slimes, etc. A. L. GENTLE. U. S. 1,575,907, March 9.

Dry reduction of iron ore. P. FARUP. U. S. 1,574,382, Feb. 23. In dry reduction by means of CO the reduced mass is cooled in an atm. contg. only a relatively small proportion of CO to avoid undue disintegration or dusting.

Dehydrating zinc ore pyrite concentrates or other mineral substances. W. R. WADE. U. S. 1,574,950, March 2. The material is allowed to fall through a furnace flue in contact with hot combustion gases and an air blast.

"Beneficiating" oxidized iron ore. C. P. MCCORMACK. U. S. 1,575,852, March 9. An oxidized Fe ore or metal-bearing product contg. Al is roasted with Na_2CO_3 so that a regulated amt. of the Al present is converted into a H_2O -sol. Na salt, which may be leached out.

Recovering magnesium and aluminum from scrap metal. A. BECK. U. S. 1,576,080, March 9. The metal to be treated is melted, MgCl_2 is added to it together with one or more substances such as MgO and CaF_2 which act as thickening agents on the MgCl_2 , the materials are stirred together and the molten metal is sepd.

Separating copper and nickel. S. GIERTSEN. U. S. 1,575,160, March 2. In order to sep. Cu from solus. contg. both Cu and Ni, they are treated with bessemerized Cu-Ni mat contg. not more than about 10% S.

Metallic gallium. S. BOYER. U. S. 1,576,083, March 9. A film of a halogen compd. is formed on the surface of a charge of metallic gallium to be purified, e. g., by treating the metal with HCl , and the charge is heated *in vacuo* to a temp. at which the film is volatilized (about 500° with chloride). This serves to produce bright clean metal.

Recovery of by-products from metals heated in retorts. H. W. TUTTLE. U. S. 1,574,137, Feb. 23. Gases and fumes such as those given off from smelting Zn ores are passed through a gas filter and passage closed to air, to sep. solids from the gases without oxidation of the latter.

Arsenic and tin. J. A. LAHEY. U. S. 1,575,217, March 2. A soln. obtained by treating scrap metals or ores or other soln. contg. As and Sn in the form of oxysalts is cooled to effect crystn. of As salts while the Sn salts remain in soln. for subsequent recovery. Sb salts may be sepd. from the soln. by sedimentation.

Refining lead. H. HARRIS. U. S. 1,573,830, Feb. 23. Molten Pb, at a temp. not over about 500° , is brought into intimate contact with a molten reagent comprising molten caustic alkali, which also may contain NaCl , and NaNO_3 or other suitable oxidizing agent is then added in such a limited amt. as to produce substantially no Pb oxide or alkali oxysalt of Pb in the resulting melt. This treatment serves to remove As, Sb, etc.

Rotary furnace adapted for metallurgical purposes. A. H. PEHRSON. U. S. 1,574,932, March 2.

Open-hearth furnace. J. D. JONES and E. E. LITZ. U. S. 1,575,000 March 2

Open-hearth furnace. G. L. DANFORTH, JR. U. S. 1,574,797, March 2.

Furnace for roasting ores. H. H. BUBAR. U. S. 1,576,033, March 9.

Apparatus for separation of gold, silver and copper ores, etc., by flotation. S. E. MEYER. U. S. 1,574,403, Feb. 23.

Apparatus for refining or separating molten lead, etc. H. HARRIS. U. S. 1,573,829, Feb. 23.

Metal chip briquets for use in cupola furnaces. G. E. GAIL, JR. U. S. 1,574,878, March 2. Dried compacted briquets are formed of chips of cast-Fe scrap or other metal and a water-glass binder applied to the material in dil. soln. The briquets withstand high temps. without premature disintegration.

Casting silicon-iron. RHEINISCHE EISENGIESSEREI & MASCHINENFABRIK AKT.-GES. Brit. 237,554, July 26, 1924. For casting Fe contg. 10% or more Si, heated molds are used. For Fe with 10% Si, temps. of 350–500° and for 20% Si a temp. of 150° for the molds may be employed.

Cast iron containing nickel and chromium. J. C. HENDERSON. U. S. 1,573,937, Feb. 23. In prepg. metal contg. definite quantities of Ni and Cr, an alloy of Fe, Ni and Cr, high in C and of relatively low m. p. contg. more Ni than Fe and Cr together (e. g., an alloy of Ni 60, Fe 27, C 1 and Cr 12%) is combined with molten Fe in a ladle.

Preventing adhesion of iron, steel or other metal plates. S. T. G. SMITH. U. S. 1,574,131, Feb. 23. Barytes is placed on the surfaces of metal plates when rolled or annealed.

Non-magnetic steel. H. BECKER. U. S. 1,574,782, March 2. A non-magnetic steel having a high yield point and elongation in normal condition comprises Mn 6–15, Ni 17–4 and Cr or metals of similar properties up to 10%.

Rolling hollow steel. E. BUMFORD. U. S. 1,574,551, Feb. 23. A hollow blank is filled with CaC_2 , rolled and the CaC_2 then removed by the action of H_2O .

Pot or crucible for heat treatment of high-speed tool steels. A. E. BELLIS and C. S. COLLINS. U. S. 1,573,535, Feb. 16. A pot or crucible adapted for holding a heat transfer bath such as a salt soln. has a wall formed of ferrous metal contg. not more than 2% each of C, silicates, aluminates or other basic impurities and capable of withstanding a temp. of 980° or higher without releasing impurities from the wall into the bath soln. The soln. is thus maintained inactive with respect to the metal being treated.

Heat-treating iron castings. W. J. DIEDERICHS and A. HAYES. U. S. 1,574,374, Feb. 23. Castings from white cast Fe are heated to above the crit. temp. for 15 min. to 5 hrs. or more but only until the Fe carbide present is practically all absorbed in the solid soln. (the combined C being generally reduced to about 0.9%) The castings are then cooled successively to a lower temp. near the crit. temp. and then to room temp. U. S. 1,574,375 specifies heating above the crit. temp., cooling to a temp. considerably below the original crit. temp., reheating to cause further structural and chem. changes and then cooling slowly at the rate of about 5° per hr. U. S. 1,574,376 specifies a process similar to that of U. S. 1,574,374 with a final cooling at a rate not less than about 7° per hr.

Heat treatment of iron castings. W. J. DIEDERICHS and A. HAYES. U. S. 1,574,377, Feb. 23. Castings of white cast Fe are heated to above the crit. temp., cooled by quenching to a temp. considerably below the original crit. temp., reheated to effect further chem. and structural changes, and then cooled to stop the changes.

Silicon iron (magnetic alloy). V. B. BROWNE. U. S. 1,574,550, Feb. 23. In making Si-Fe contg. sufficient Si to adapt it for use as a magnetic alloy and not over 0.03% C, the C in the refined Fe is reduced by adding Fe ore to the bath until no further reduction of C is obtained by further addn. of ore; sufficient ferro-Si is added to produce the necessary heat to maintain the metal molten during a Bessemer blow, the metal is transferred to a Bessemer converter and over-blown to remove the Si which has been added and substantially all the remaining C, and is then transferred to a ladle and the necessary Si is added. Cf. C. A. 20, 735.

Alloys for bearings. METALLBANK UND METALLURGISCHE GES., AKT.-GES. Brit. 237,583, July 25, 1924. Bearing alloys comprise Pb and alkali metals with or without alk. earth metals. Li 0.1 and 0.5 or less Na may be present. K 0.1% or less and 0.5% of an alk. earth metal may be present as may also small quantities of Cu, Ni, Co, Zn, Mg, Bi, Cd, As, Sb, Sn, Al, Si, Se, P or S.

Treating fumes from smelting copper alloys. L. LO CASCIO and B. BRUZZONE. Brit. 237,232, July 20, 1924. Gases evolved from an externally heated furnace for extg. Cu from its alloys are passed first through a steam generator in which the waste heat is utilized and then through a filter for recovery of ZnO . An app. is described.

Osmium alloy. E. HAAGN. U. S. 1,574,966, March 2. An alloy for pen points

which is non-fibrous and of greater hardness than the natural Os-Ir alloy occurring in Pt ore comprises Os 85 together with Pt 10 and Rh 5%.

Purifying molten metals. F. M. BUCKER. Brit. 237,088, July 9, 1924. An Fe-Cr alloy may be treated with an alloy of Pb 92 and Mg 8%. Other purifying mixts. comprize Mg shavings, Pb shot and powd. Mn-Si, briquetted together; Mn-Si in an alloy of Pb 56 and Mg 17 parts; ferro-Mn in an alloy of Pb 33 and Mg 16 parts; and Mg shavings with Mn-Si.

Dental alloy. C. C. VOGT. U. S. 1,574,714, Feb. 23. An alloy of Ag, Cu and Sn with Cr, W, V, Mn, Mo or Ta is prepd. for forming dental amalgams with Hg.

Salt mixtures for heat treatment of metals. BELLIS HEAT TREATING CO. Brit. 237,337, April 22, 1924. A fused mixt. of NaCl 39 and Na₂CO₃ 61% or other "eutectic" mixt. is used for heat treatment of steel having a C content of 0.4% at a temp. of about 815°. CaCl₂ 71 and NaCl 29% also may be used.

Heat treating of magnetic materials. D. S. O'DONOVAN. U. S. 1,575,178, March 2. Mech. and magnetic features of material handling during heat treatment.

Tempering metals. J. W. VANMETER. U. S. 1,573,784, Feb. 16. Internal-combustion engine cylinders or other articles to be tempered are heated in a non-oxidizing atm., and, while excluding air, are treated under pressure, with products generated from Cl, sawdust, Fe filings, NaCN and C₂H₆ or other hydrocarbon.

Pickling metal. W. C. KRONQUEST. U. S. 1,574,823, March 2. Sheet steel strips or other metal articles are immersed in an aq. soln. of H₂SO₄ or other acid and electrolyzed as anode, with an inert cathode such as Pb.

Apparatus for casehardening small articles. G. A. H. MEKER. U. S. 1,575,633, March 9.

Tin plate. G. M. HARRIS. U. S. 1,576,274, March 9. Plates, after hot rolling, are black annealed, black pickled and swilled, dried at a temp. not substantially over 100°, cold-rolled and then prepd. for tinning and tinned.

Apparatus for annealing the ends of pipe. C. W. BARDEEN. U. S. 1,575,087, March 2.

Soldering aluminum. E. CONTI. Brit. 237,224, July 21, 1924. A solder is formed of Sn 52-66, Zn 23-46 and Cd 2-11% and to a fused mixt. of these metals there is added NaCl, NH₄Cl or alum.

Welding different metals to each other. F. JORDAN. Brit. 237,072, June 20, 1924. Fe and Al bands from sep. spools are heated to about 350°, rolled together and welded by rolling again at 550°. In welding Al and Zn bands together, the Zn is heated to 250° and the Al to 450° and the welding is effected in a single operation.

Attaching labels to aluminum ware. A. M. HAGEMAN. U. S. 1,573,826, Feb. 23. A portion of the surface of the ware is heated to roughen it so that it will retain an adhesive.

Ingot mold. E. GATHMANN. U. S. 1,573,486, Feb. 16.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Pyrogenic acetylene condensations. Cuprene-tar. P. SCHLÄPFER AND O. STADLER. *Helvetica Chim. Acta* 9, 185-99 (1926).—Cuprene (also known technically as Carben), and consisting principally of rather unreactive and insol. solid hydrocarbons, is obtained catalytically by passing technical C₂H₂ over Cu at 300°; it is accompanied by a tarry by-product and satd. and unsatd. gases. The reaction yields 75-80% cuprene, 5.5-7% tar, and 13-17% gases. Cuprene-tar is a greenish blue liquid, d. 0.878-0.910. It is strongly unsatd., neutral and consists almost entirely of aromatic and aliphatic hydrocarbons. The material was fractionated at 12 mm. up to 70°; then at 0.3-0.5 mm. All but 1.6% distd. below 220°. Fractional distn. and treatment with concd. H₂SO₄ and Br show that the tar consists mainly of satd. aromatic hydrocarbons, especially of the C₆H₆ and C₁₀H₈ series, with small quantities of anthracene derivs. The C₆H₆ and C₁₀H₈ nuclei are substituted by one or more Me, Et and seldom Pr groups. Next in importance are olefins and styrenes. Hexylene, heptylene and octylene were identified. Small quantities of paraffin hydrocarbons were found in the lower fractions. The fraction b.p. 85-125° contains a very small quantity of a blue substance, of unsatd. hydrocarbon nature. In washing the cuprene-tar with concd. H₂SO₄, some condensation takes place by addn. of the aromatic hydrocarbons to the olefins. E. H. V.

The alcoholates of magnesium and their application to the synthesis of alcohols.

II. Tests with isobutyl and isoamyl alcohols. M. A. TERENTIER. *Bull. soc. chim.* 37, 1553-7(1925); cf. *C. A.* 19, 633.—By passing the vapors of primary alcs. over Mg, heated to 250–300°, Mg alcoholates are obtained. By passing over these alcoholates alc. vapors at 360–400° there are formed condensed alcs. with double the no. of C atoms in the original alc. (cf. Terentier, *C. A.* 19, 633). The present article has to do with iso-Bu and iso-Am alcs. For a detailed study of iso-AmOH cf. Guerbet, *Bull. soc. chim.* 21, 437, and Nef, *Ann.* 318, 137. Dehydrated iso-BuOH vapors, passed over powd. Mg at 280–300°, yield (iso-BuO)₂Mg as a white, infusible powder. By passing iso-BuOH vapors over this alcoholate, for 3–5 hrs. at 380–410°, a condensation of the alc. with the alcoholate is effected. At a temp. higher than 380°, the b. p. of the alc. falls from 108–9° to 96–7°, in consequence of the formation of iso-PrCHO as an intermediate product. The solid residue from this reaction is largely Mg(OH)₂. The liquid product represents 60–70% of the original alc. and yields, upon rectification, the following substances: (1) A few drops of iso-PrCHO, b. 61°, recognizable by its odor and its color with Schiff's reagent. (2) (iso-Pr)₂CO (probably), b. 124–6°, d_4^{20} 0.8087, and n_D^{20} = 1.4007. (3) A fraction b. 147–50° (about 10% of the original alc.), consisting principally of iso-BuO₂CCHMe₂, b. 149°, d_4^{20} 0.8475 and n_D^{20} 1.4010. (4) A fraction b. 155–70° (about 5% of the original alc.). Its principal fraction, b. 164–70°, n_4^{20} 1.426 and d_4^{20} = 0.8232, corresponds to C₈H₁₈O and is probably diisobutyl alc., Me₂CHCH₂CM₂CH₂OH. (5) Higher fractions, b. 170–205°. One substance has been isolated (about 5% of the original alc.), b. 199–202°, n_D^{20} 1.4208, d_4^{20} 0.8545, corresponding to octyl isobutyrate, Me₂CHCO₂CH₂CM₂CH₂CHMe₂ (I). The Me₂CHCHO formed in the 1st fractions of distillation as an intermediate product, condenses on itself to form Me₂CHCO₂CH₂CHMe₂. Also this aldehyde reacts with Mg(OCH₂CHMe₂)₂ to form octylic aldehyde, which condenses with Me₂CHCHO to form I. This I in turn reacts with Mg(OH)₂, giving the corresponding octyl alc. and the (Me₂CHCO₂)₂Mg and, finally, the latter decmps. to MgCO₃ and (Me₂CH)₂CO. iso-AmOH, similarly treated, reacts normally with Mg, yielding a decylic alc., b. 210–3°, n_D^{20} 1.480, d_4^{20} 0.8322. H. W. GIBSON

Some experiments on the assimilation hypothesis. D. VORLÄNDER. *Ber.* 58B, 2656-8(1925).—V. has attempted to det. whether it is possible to synthesize HCHO from CO₂ and H₂O in the light without the intervention of protoplasm or organized matter by using dimethylhydroresorcinol (I) to detect any HCHO formed and to remove it from the field of action and thus render the reaction irreversible (the compd. which I forms with HCHO is sol. only to the extent of about 0.0005 g. in 100 cc. satd. aq. soln. at 19° and even less in the presence of excess of I). Thus far he has not been able to detect the formation of any HCHO, even after weeks of illumination with the ultra-violet light from a Hg-quartz arc light or after months with sun- and daylight, in satd. solns. of I in a current of CO₂ and contg. various added substances (UO₂SO₄, Ce carbonate or chloride, Ti sulfate, FeSO₄, C₃H₅N, etc.). Both the solid I and its aq. solns. are stable indefinitely when protected from the air, but in the air, more rapidly with H₂O₂ or O₃, the reagent gradually oxidizes to dimethylglutaric and *asym*-dimethylsuccinic acid; with O₃ in Na₂CO₃ is formed a Na₂CO₃-sol. monobasic acid, m. about 142°, forming with PhNHNH₂ a dark red compd. m. around 180°. C. A. R.

Natural oleic acid. A. LAPWORTH, E. N. MOTTRAM AND MRS. L. PEARSON. *Food Investigation Board, Report for the year 1924. Dept. Sci. Ind. Research* 1925, 68; cf. *C. A.* 19, 1851, 1930. L. W. RIGGS

Thermal decomposition of unsymmetrical diacyl peroxides. FR. FICHTER AND HANS ERLÉNMEYER. *Helvetica Chim. Acta* 9, 144–52(1926).—F. and E. aimed to discover the mechanism of the thermal decompn. of diacyl peroxides to give hydrocarbons. They have shown that the decompn. by heat at the explosion temp. is represented by RCOO.OOCR = R.R + 2CO₂ (I). This formation of the hydrocarbon may take place by the intermediate decompn. into CO₂ and the free radicals R, followed by polymerization of the 2 radicals: RCOO.OOCR = R + 2CO₂ + R (II); R + R = R.R (IIa). AcO.OBz, when exploded in a bomb at 200°, without a solvent, gives PhMe, which decmps. further to C₆H₆, Ph₂ and C₆H₅. A mixt. of (AcO)₂ and (BzO)₂, heated similarly, gives no PhMe, but C₆H₆ and much more Ph₂ than AcO.OBz. (AcO)₂ and I when exploded give no MeI. Ph₂ at 500–600° gives C₆H₆ and some Ph₂C₆H₅; the same products are obtained from (BzO)₂. These expts. show that in such thermal decmps. the alkyl or aryl radicals do not become free, but remain in their original spheres of attraction. E. H. VOLWILER

Ethers derived from propylene chlorohydrin. A. DEWAEL. *Bull. soc. chim. Belg.* 34, 343–6(1925).—MeCHClCH₂OMe, from MeCHClCH₂OH (I) and Me₂SO₄,

b_{768} 98–9°, d_{20} 0.9946, n_D^{20} 1.40754, some $\text{CH}_3\cdot\text{CClMe}$ being a by-product of the reaction. $\text{MeCHClCH}_2\text{OEt}$, from **I**, EtOH, and H_2SO_4 , b_{768} 116–7°, d_{20} 0.9828, n_D^{20} 1.41285. $\text{MeCHClCH}_2\text{OPr}$, by mixing **I** with SO_2Cl_2 and addn. of PrOH , b_{768} 139°, d_{20} 0.9399, n_D^{20} 1.41912. $\text{MeCHClCH}_2\text{OCH}_2\text{CH}_3$, from **I**, $\text{CH}_3\cdot\text{CHOH}$, and H_2SO_4 , b_{768} 142–3°, d_{20} 0.9683, n_D^{20} 1.42887. ($\text{MeCHClCH}_2\text{O}$)₂, by heating **I** with SO_2Cl_2 , b_{768} 188°, d_{20} 1.109, n_D^{20} 1.44675. W. B. PLUMMER

Some derivatives of dipropyl ketone. LOUIS MATHUS AND FERNAND GIBON *Bull. soc. chim. Belg.* **34**, 303–13 (1925).—Various compds. have been prepd. during attempts to prep. 3,4-heptanediol (**I**) from Pr_2CO (**II**). Reduction of **II** to Pr_2CHOH (**III**) and dehydration of **III** gave 3-heptene (**IV**), b_{768} 95.8°, d_{20} 0.7016, n_D^{20} 1.40419, all attempts to sep. **IV** into 2 isomers failed. Esterification of **III** gave 4-bromoheptane, b_{11} 55°, b_{760} 159–60°, d_{20} 1.1389, n_D^{20} 1.4472, and 4-chloroheptane, b_{768} 144–5°, d_{20} 0.8619, n_D^{20} 1.4199. From **IV** were prepd. 3,4-dibromoheptane, b_{11} 98–9°, and 3,4-dichloroheptane, b_{760} 179–81°, d_{20} 1.0260, n_D^{20} 1.45036. With HOCl **IV** gave a mixt. of the 2 isomeric chlorohydrins, from which mixt. solid KOH formed 20% of the corresponding oxide $\text{EtCH}\cdot\text{CHPr}\cdot\text{O}$, b , 131–2°, d_{20} 0.8338, n_D^{20} 1.4134, but which could not be con-

verted into **I** by hydrolysis. **I** was, however, obtained in small yields from the foregoing mixt. of chlorohydrins by refluxing with $\text{AcOK} + \text{AcOH}$ and finally sapon. with NaOH , b , 98–9°, b_{761} 212°. Further expts. indicate that the bromoheptanes are subject to isomerization in the sense $4\text{-Br} \rightarrow 3\text{-Br} \rightarrow 2\text{-Br}$. W. B. PLUMMER

Chemistry of the higher fungi. XVIII. Muscarine question. BRUNO GUTH *Monatsh.* **45**, 631–48 (1925).—Choline gives a HCl salt which could not be completely dried; the chloroplatinate (**I**), m . 242°, the chloroaurate (**II**), m . 250° and is stable only when pure. HgI_2 first ppts. an amorphous compd., changing to the cryst. $\text{C}_6\text{H}_{14}\text{NOI}\cdot 2\text{HgI}_2$, light yellow, dissociated by boiling H_2O . In EtOH HgCl_2 gives the salt $\text{C}_6\text{H}_{14}\text{NOCl}\cdot \text{HgCl}_2$, m . 170°; recrystn. from H_2O or dil. EtOH gives a salt with 67% Hg , corresponding approx. to the salt $\text{C}_6\text{H}_{14}\text{NOCl}\cdot 6\text{HgCl}_2$ (Mörner, *Z. physiol. Chem.* **22**, 520 (1896)). Oxidation of **I** with HNO_3 (d 1.52) gives a compd. ($\text{Me}_3\text{NCl}\cdot\text{CH}_2\text{ONO}$)- AuCl_3 (?), m . 133–4°; since this contains an extra N and 1 less Cl , it is of no interest in connection with the muscarine question. Oxidation of **II** gives the known HNO_3 ester of choline. Oxidation of choline sulfate with KMnO_4 gave betaine, identified as the AuCl_3 salt. The sapon. of trimethylammonium acetal gave a product, the PtCl_4 salt of which, on crystn., gave a series of fractions, m . 230°, 227°, 215°, 209°, and 204°; these showed the same compn., ($\text{Me}_3\text{NCl}\cdot\text{CH}_2\text{CHO}$)₂ PtCl_4 , and contained $3\text{H}_2\text{O}$ instead of the reported 2 mols. The m . p. of the various fractions may be due to differences in the H_2O content or to polymorphism or possibly to impurities which do not show in the analytical results. The so-called choline- or pseudomuscarine is to be stricken from the literature, since it is not obtained by the reported directions. A careful fractionation of the bases from fly agaric indicates that these bases consist essentially of choline and that a substance of the compn. of muscarine is not present. C. J. WEST

Ethyl β -hydroxybutyrate. A. DEWAELE. *Bull. soc. chim. Belg.* **34**, 341–2 (1925). $\text{MeCH(OH)CH}_2\text{CO}_2\text{Et}$, b_{768} 184–5°, d_{20} 1.017, n_D^{20} 1.4182, the b . p. previously reported in the literature being lower and apparently that of the α -compd. W. B. P.

Constitution of α -ketogluconic acid. A reply. M. HÖNIG. *Ber.* **58B**, 2644–6 (1925).—Cf. van Niel and 't Hooft, *C. A.* **20**, 360. C. A. R.

The preparation of aspartic acid from asparagine. FR. PACHLOPNIK. *Z. Zuckerind. cecoslov. Rep.* **50**, 139–41 (1925); *Listy Cukrov.* **43**, 348 (1924–5).—Asparagine is hydrolyzed with dil. HNO_3 instead of HCl as called for in most methods. After 3 hrs.' boiling the excess acid is neutralized with NH_3 , the mixt. evapd. to dryness, and extd. with EtOH. The lower soly. of aspartic acid in EtOH results in much higher yields (93%) than previous methods. W. L. BADGER

Attempts to prepare 8-alkylallantoins; also, a consideration of hydroxonic acids and 5-aminohydantoin. HEINRICH BILTZ AND HELMUT HANISCH. *J. prakt. Chem.* **112**, 138–63 (1926).—No allantoin could be obtained by the action of Ac_2O , POCl_3 , SOCl_2 or HCl upon a mixt. of $\text{CO(NH}_2)_2$ and free alloxanic acid; substituted ureas likewise showed no reaction. Attempts to transform hydroxonic acid into its amide (allantoin) or its chloride failed. MeNH_2 gave the methylammonium salt, easily sol. in H_2O . The K salt, $\text{C}_4\text{H}_5\text{O}_4\text{N}_4\text{K}_2\cdot\text{H}_2\text{O}$, leaflets, turns yellow at 280°, decomps. 313°; from H_2O crystals. the mono- K salt. Hydroxonic acid is not changed by heating the free acid or

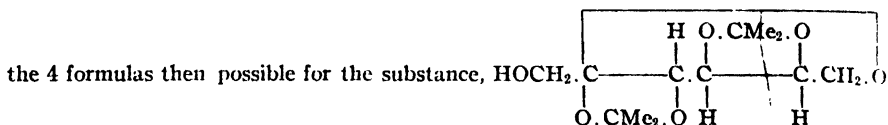

its mixt. with $\text{Ba}(\text{OH})_2$ and thus does not give rise to 5-aminohydantoin. Attempts to reduce allantoxidine also failed as did attempts to condense it with MeNCO . Heating diacetylaminohydantoin with H_2O gives 94% of 5-acetylaminohydantoin (I), sinters 199° , m. $218-9^\circ$; with CH_2N_2 this gives a 3-Me deriv., sinters 186° , m. 210° , which with Ac_2O yields a 1-Ac deriv. (II), sinters 204° , m. $221-2^\circ$. I gives a Na salt, crystg. with H_2O , decomp. about 106° ; Ag salt, crystg. with H_2O , darkens in the light. Numerous attempts to prep. the free 5-aminohydantoin from its HCl salt failed. Uric acid (100 g.) gives 45 g. allantoin, 30 g. 3-methylallantoin, 13-15 g. 3-methylxonic acid (K salt), which is reduced by Na-Hg to 9 g. 3-methylhydroxonic acid, m. $246-7^\circ$; it is decompd. by warm NaOH but is only slightly changed by boiling with 2 N HCl for 15 min.; NH_4 salt, decomp. about 260° ; crysts. with H_2O ; the strength of the acid is indicated by the slight tendency of this salt to hydrolyze in H_2O . K salt, decomp. above 270° ; crysts. with H_2O . Ag salt, turns brown 156° , black 170° , decomp. 192° ; Ba salt, decomp. above 265° ; Pb salt, yellow at $256-8^\circ$, decomp. about 350° . Et ester, m. $172-3^\circ$; Me ester, sinters 199° , m. $210-1^\circ$. Ac_2O gives 25% II; this is also obtained by the action of CH_2N_2 upon 1-acetyl- or 1,3-diacetyl-5-acetylaminohydantoin. Boiled with MeOH satd. with HCl, II gives nearly quant. 3-methyl-5-aminohydantoin as the HCl salt (III), m. $239-42^\circ$, decomp. about 350° ; perchlorate, m. 222° , rhodanate, m. $188-9^\circ$ (decompn.). III and KCNO give 85% of 3-methylallantoin. The free base is obtained from III and MgO as a light brown sirup. With PhCNO this gives a mixt. of phenyl- and diphenylurea.

C. J. WEST

Degradation of some uric acid glycol ethers by alkali. H. BILTZ AND H. KLEIN. *Ber.* 58B, 2740-7 (1925).—It was found (C. A. 16, 2451) that a no. of uric acid glycol ethers are converted by boiling H_2O into the corresponding allantoin but that the 3,7- and 3,9-di-, 1,3,7-tri- and 1,3,7,9-tetra-Me derivs. are resistant towards boiling H_2O . Also, uric acid glycol di-Me ether on solu. in KOH at room temp. and immediate acidification gives allantoin in good yield and it was hoped that the above derivs. which are stable towards H_2O might undergo the same reaction, but this proved to be the case only with the (sym.) Me_4 compd., 1.5 g. of the (di-Me) ether giving 0.04 g. tetramethylallantoin hydrate, m. $86-93^\circ$. The others underwent further and novel degradations. The 1-methyluric acid was prepd. in the usual way from methylvioluric acid, m. $202-3^\circ$, which was obtained in 8.0-8.6 g. yield from 20 g. theobromine oxidized with KClO_3 and HCl, filtered and treated with NH_2OH HCl on the H_2O bath. The 1- and 7-methyluric acid glycol di-Me ethers are strikingly stable towards alkali; 9% KOH hardly attacks them in 2 min. at room temp. and although NH_3 is evolved on longer continued action the reaction is not complete in 2 days; only 20% KOH completely decomp. them in 9 hrs. but no definite products could be isolated. The action of concd. alkalies on 3,7- and 3,9-dimethyluric acid glycol ethers and subsequent acidification results in a new type of degradation in which HNCO is evolved and which is therefore called the "cyanic acid degradation". It seems that for its occurrence there must be only 1 Me group (in position 3) in the pyrimidine nucleus; this is split off as NH_2Me , 1 CO group as CO_2 and the NHCO group as HNCO , while the 4-RO group is hydrolyzed, the products being the hitherto unknown ethers of 1-methyl-5-hydroxyhydantoin (I). The reaction proceeds in steps; with KOH, only a small amt. of NH_2Me is evolved; as acid is slowly added, the odor of NH_2Me becomes perceptible and disappears only when the soln. has become acid and now the CO_2 and HNCO are evolved. In the prepn. of 3,7-dimethylchlorisouric acid by chlorination of theobromine in AcOH (C. A. 8, 3554) the AcOH should contain about 1.7% H_2O (such an acid m. 13.7°). 3,7-Dimethyluric acid glycol di-Et ether is decompd. only about 50% by 30% KOH at room temp. in 15 min., completely by 40% KOH in 1 hr. or in 15 min. by 20% HCO_2H on the H_2O bath; 3 g. allowed to stand 2 days in 30% KOH and then neutralized yielded 0.5 of the Et ether of I, m. $99.5-100.5^\circ$, sol. in about 20 parts boiling AcOEt, 16 of H_2O , 12 of C_6H_6 , 10 of PhMe, reduced by HI to 1-methylhydantoin. Me ether (0.15 g. from 2 g. of the glycol di-Me ether), m. 118° , could not be isolated from the reaction product of the 3,9-dimethylglycol ether. 1,3,7-Trimethyluric acid glycol di-Me ether (II) boiled with 1-1.5% KOH splits off NH_2Me and reduction with HI of the sirup obtained by neutralizing, evapg. and extg. with alc. gives about 20% 1-methylhydantoin; allowed to stand several days in 33% KOH 16 g. of II gives 7.1 g. of a compd. $\text{C}_8\text{H}_{14}\text{O}_4\text{N}_4$, probably 1-methyl-4-dimethylureido-5-methoxy- $\Delta^{3,4}$ -2-glyoxalone, m. $123-4^\circ$, acts towards acids as a weak base, cannot be methylated with CH_2N_2 or Me_2SO_4 , sol. in about 8 parts boiling AcOEt, loses some McNH_2 when heated moist at 85° , is hardly attacked by H_2O_2 ; perchlorate; HCl salt, decomp. 190° . Reduction of the base with concd. HI on the H_2O bath gives 6.7 g. of a polyiodide (80.7% I), prisms with green metallic luster, brown by transmitted light; 11 g. of this, treated with SO_2 ,

then CO_2 , PbCO_3 and H_2S , yielded 0.21 g. of a high red substance, sublimes about 350° and has approx. the compn. $\text{C}_8\text{H}_8\text{O}_7\text{N}_2\text{S}$ (C 41.4, H 3.2, N 20.6, S 21.9). With concd. NH_4OH in sealed tubes at 100° , 3.2 g. II gives 1.2 g. 1-methyl-4-methylimino-5-methoxyhydantoylamide, m. 254° (decompn.), sol. in 8-10 parts hot MeOH and EtOH, sol. in acids, reprecipitated by alkalis, gives off NH_3 with hot concd. HCl; methylamide (1.1 g. from 3 g. II with 33% MeNH $_2$), m. 270° (decompn.), gives the biuret reaction, as does the oily ethylamide. C. A. R.

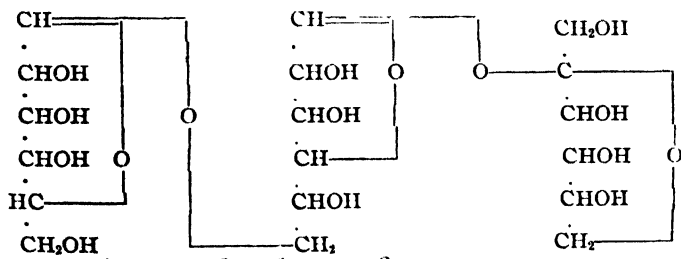

Acetone compounds of the sugars and their derivatives. III. Constitution of β -diacetonfructose. HEINZ OHLB. Ber. 58B, 2577-84 (1925); cf. C. A. 19, 249. The relatively great stability of β -diacetonfructose (I) towards acids indicates that the Me_2CO residue not on the reducing group is attached to 2 sec. carbinol groups. Of

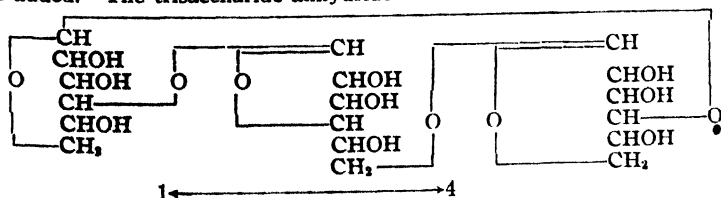

(II) seems, by exclusion, to be the correct one. Its Me ether (III) with dil. acids gives a sirupy methylfructose (IV), which does not crystallize even when seeded with the 3-methylfructose (V) obtained from methyl- α -diacetonfructose according to Irving and Hynd. IV, therefore, cannot have the MeO group on C atom 3. The change in rotation of III on removal of the Me_2CO groups follows the same characteristic course as that of I, i. e., the rotation passes through a negative minimum, showing that in the methylation of I there is no change in structure and that in the removal of the Me_2CO residues the deriv. of an unstable fructose changes into a deriv. of the stable fructose. Again, III with PhNHNH_2 yields red-brown, easily resinified flocks and not 6-methylglucosazone (Helfferich and Becker, C. A. 19, 250) and can therefore not have the MeO group on C atom 6, leaving C atom 1 as the only possible position for the MeO group in III or the free HO group in I. O. attempted to obtain further confirmation of this view by oxidative degradation. I is attacked only exceedingly slowly by neutral KMnO_4 , alkalis accelerate the reaction, which, however, is still far slower than with diaceton-glucose or α -diacetonfructose under the same conditions and almost comes to a standstill when 2 atoms O have been used up. The product, obtained in excellent yield, is the K salt of an acid $\text{C}_{12}\text{H}_{18}\text{O}_7$ (VI), which, if II is the correct formula for I, should give on removal of the Me_2CO groups a 2-ketogluconic acid. The product (VII), however, is isomeric, not identical with either the Botroux-Kiliani or the Hönig and Tempas 2-ketogluconic acid (cf. K. C. A. 20, 1057). This interesting isomerism is being investigated. III, prepd. with Ag_2O and MeI (yield, 11.4 g. from 20 g. I), by Preudenberg and Hixon's method (C. A. 18, 818) (yield no better) or with $\text{Me}_2\text{SO}_4\text{---NaOH}$ (least satisfactory method), m. $48\text{--}9^\circ$, $[\alpha]_D^{20} = -38.26^\circ$ (abs. alc., c 2.07), -29.53° (CHCl_3 , c 5.08); 0.4538 g. in 3 N alc. H_2SO_4 at $38\text{--}40^\circ$ gave $[\alpha]_D^{20} = -30.3^\circ$, -27.55° , -50.69° , -52.4° (const. value) after 10 min., 2, 19 and 24 hrs., resp. Calcd. for IV, the final value is -73.9° ; the isolated sirupy IV has $[\alpha]_D^{20} = -49.82^\circ$ (MeOH, c 2.162). K salt of VI, needles with $1\text{H}_2\text{O}$ (yield, 87%), very hygroscopic when anhyd., $[\alpha]_D^{20} = -31.75^\circ$ (H_2O , c 1.748), decomps. completely above 350° under 15 mm.; PhNH $_2$ salt, $\text{C}_{18}\text{H}_{25}\text{O}_7\text{N}$, m. 120° , $[\alpha]_D^{20} = -31.3^\circ$ (CHCl_3 , c 1.237), begins to decompose in a high vacuum at a bath temp. of 120° , yielding first PhNH $_2$ and then the free VI as a brown, very viscous oil solidifying to a glassy mass, also obtained in 9.5 g. yield from 16.5 g. of the K salt in the calcd. amt. of ice-cold 2 N H_2SO_4 quickly extd. with much Et_2O ; it forms no difficulty sol. salts with heavy metals or alkalis. The K salt (6.6 g.) in 100 cc. N H_2SO_4 at about 40° shows $\alpha_D = -2.1^\circ$, -1.65° , -1.45° , -1.27° , -3.1° , -3.2° , -3.37° , -3.5° (const. value) after 0, 1, 2, 3, 20, 21, 22 and 24 hrs., resp.; calcd. for VII, the final value, $[\alpha]_D^{20}$, is -89.8° . K salt of VIII, microcryst., very hygroscopic powder with $1\text{H}_2\text{O}$, $[\alpha]_D^{20} = -70^\circ$ (c 1.620), -74° (0.1 N HCl, c 1.608), or calcd. for the free VII, -95.35° ; although the solns. were prepd. as rapidly as possible and at 0° , no mutarotation was observed. Hydrolyzed in 100 cc. N HCl at 40° , 9.5 g. VI gave a final rotation of -40° (calcd. for VII, -69.13°); this difference from the results obtained with H_2SO_4 cannot be ascribed to exptl. errors but is to be referred chiefly to a sp. action of the HCl, for a similar difference was observed with III hydrolyzed with HCl; as the HCl was evapd. off *in vacuo* at 30° the soln. became a deeper and deeper brown and the distillate did not become neutral after repeated addns. of fresh portions of H_2O . The metal salts of VII are all easily sol. in H_2O ; brucine salt, $\text{C}_{25}\text{H}_{30}\text{O}_{11}\text{N}_2\cdot 3\text{H}_2\text{O}$, m. 166°

(decompn.). In dil. AcOH with PhNHNH₂ on the H₂O bath VII yields an *osazone phenylhydrazine salt*, C₂₄H₂₈O₈N₄, deep red, m. 102–3°. IV. Constitution of *diacetonegalactose*. HEINZ OHLE AND GERTRUD BEREND. *Ibid* 2585–9; cf. Svanberg, C. A. 19, 3481.—The observation of S. that diacetonegalactose (I) with KMnO₄ gives diacetone-*d*-galacturonic acid (II) has been confirmed. The oxidation cannot be controlled as well as with β-diacetonefructose and diacetone-mannose; even under the mildest conditions a not inconsiderable part of the I is degraded all the way down to (CO₂H)₂. A 50% excess of KMnO₄ gives the best results (50–60% of the K salt of II). O. and B. agree with S. that the end primary CH₂OH group of the galactose is also present in I but not that there is an O bridge between C atoms 1 and 3. I is also formed from galactose and Me₂CO in the presence of CuSO₄, *i. e.*, in the absence of mineral acids, although in very poor yield (0.2 g. from 1 g. galactose) (doubtless owing to the extremely slight soly. of the sugar in Me₂CO), and under these mild conditions there is no shifting of the O bridge, so that the same ring structure must be present in I as in galactose; from the work of Haworth, Ruell and Westgarth, the O bridge is very probably between C atoms 1 and 5 (C. A. 19, 973). I is best prepd (yield, 50–60%) from 20 g. galactose shaken 20 hrs. in 1 l. Me₂CO with 10 cc. concd. H₂SO₄; in C₂H₅N with the calcd. amt. of Ac₂O at 38–40° it gives the *acetate*, m. 108°, [α]_D²⁰ –48.08° (CHCl₃, *c* 4.832). *K salt* of II, needles with 0.5 H₂O, very hygroscopic, decomp. above 200°, [α]_D²⁰ –61.09° (H₂O, *c* 2.046). Free II, m. 157°. *d*-Galacturonic acid (III), from II or its K salt and *N* H₂SO₄ at 38–40°, is isolated as the curdy basic Pb salt or the Ba salt, cryst. powder with 2 H₂O, decomp. about 180°, [α]_D²⁰ 25.1° (H₂O, *c* 1.394); free acid, [α]_D²⁰ 46.7° (Ba salt in the calcd. amt. of HCl, *c* 1.038); no mutarotation was observed although the solns. were rapidly prepd. at 0°. *Brucine salt* of III, C₂₈H₃₆O₁₁N₂·H₂O, m. 189° (decompn.), [α]_D²⁰ –7.5° (H₂O, *c* 1.328). A soln. of III treated dropwise with PhNHNH₂ as long as the base dissolved yielded in a short time a light yellow cryst. crust, probably of the *phenylhydrazone phenylhydrazine salt*, which could not be recovered when dissolved in boiling H₂O; this soln., heated with PhNHNH₂ and dil. AcOH on the H₂O bath, gave the *phenylosazone phenylhydrazine salt*, C₂₄H₂₈O₈N₄, brown, m. 140° (decompn.). C. A. R.

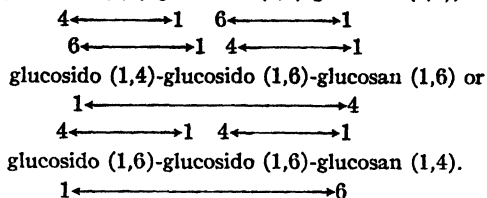

Nomenclature of polysaccharides. M. BERGMANN. *Ber.* 58B, 2547–50(1925).—B. suggests that O bridges between 1 component sugar of a polysaccharide and another component sugar be represented by a double-headed arrow written above or below the name of the polysaccharide and extending to the names of the 2 component sugars united by the O bridge in question; the positions at which the O bridge is attached are to be indicated by nos. before and after the arrow. Thus, raffinose, for which Haworth, Hirst and Ruell give the structure

would be galactosido (1,5)-glucosido (1,4)-fructosido (2,6). If it is desired to take the spatial relationships into account also, the necessary designations (α -, β -, *d*-, *l*-) can easily be added. The trisaccharide anhydride

could be written glucosido (1,6)-glucosido (1,4)-glucosan (1,6),

Naturally, the arrows are to be used only when no clear and intelligible name is possible without them. For trehalose and related compds. the name glucosidoglucoside shows that both sugars are joined through their glucosidic group and sucrose is sufficiently described by the name glucosido(1,4)-fructoside(2,6). The ending "osan" (from ose-anhydride) is suggested for all anhydrides derived from a disaccharide by loss of H_2O involving the carbonyl or lactol group, the term anhydro-sugar being reserved for those derivs. in which this group is still intact.

Action of diazomethane on cellulose. M. NIERENSTEIN. *Ber.* 58B, 2615(1925). N does not agree with Schmid (*C. A.* 20, 743) that cellulose does not react with CH_2N_2 . Geake and N. (*C. A.* 8, 3563) obtained from cotton cellulose and CH_2N_2 products with 1.5-4.2% MeO.

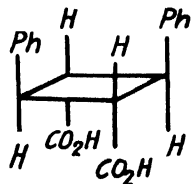

The chemistry of glycogen. JAMES C. IRVINE AND H. GILCHRIST. *Food Investigation Board report for the year 1924. Dept. Sci. Ind. Research* 1925, 63-6. The reactions of glycogen from different sources varied greatly, although no analytical difference could be detected. It is suggested that some of the impurities may be present in solid soln. The study of glycogen free from extraneous substances and consisting exclusively of $\text{C}_6\text{H}_{10}\text{O}_5$ units, can be approached through the acetylation of the polysaccharide, and a method has been devised whereby pure glycogen triacetate can be prepd. The account of this compd. given in the literature has been corrected as it has been shown that unless special methods of purification are adopted 1 mol. of AcOH remains persistently in combination with the triacetate. Acetylation removes N and P completely, but the elimination of the last traces of Fe is difficult. L. W. RIGGS.

Chemistry of the polycyclic structures in relation to their homocyclic unsaturated isomerides. II. Intra-annular tautomerism. III. The simulation of benzenoid properties by the five-carbon intra-annular nucleus. R. F. HUNTER. *Chem. News* 132, 117-22, 133-7(1926); cf. *C. A.* 18, 1651.—Theoretical discussion of various papers from English lab.

Relation between optical rotatory power and structure in polysaccharide chemistry. HANS PRINGSHEIM AND JESAJA LEIBOWITZ. *Ber.* 58B, 2808-14(1925).—The relations between mol. rotation and structure developed with Hudson (*C. A.* 20, 583) for amylobiose (I) and amylotriose (II) have been extended to the hexosans. Assuming that in the formation of di- (III) and trihexosan (IV) from I and II, resp., with cold concd HCl the union ruptured by the HCl is the same in both cases, i. e., that III and IV bear to each other the same relation as I and II, the difference between the mol. rotations of the corresponding pairs of sugars should be the same. The differences actually found are: II — I, 28,100; IV — III, 30,400; and for the Ac derivs., 41,600, 42,800, resp. Calculus made in this way are in harmony with the view that of the 2 formulas suggested for III and IV (*C. A.* 19, 974) the sym. is the correct one. These calcs. may be extended to the polyamyloses; the differences between the mol. rotations of tri- (V) and diamylose (VI) (29,500) and of their acetates (42,600) indicate that in the expansion of the ring of VI to V the same radical is introduced as in the expansion of III to IV. The members of both polyamylose series have almost exactly the same sp. rotation (α -series, 136-9°, β -series, 152-7°). IV ($[\alpha]_D$ 166°) and III (155°) are then apparently not the true elementary substances of amylopectin (196°) and amylose (189°), resp.; P. and L. believe that the 2 hexosans are produced from the true, very labile elementary substances of the starch constituents by an inner rearrangement, but are still closely related to them. Calcs. of the sp. rotation of VI on the basis of the structure suggested by Karrer and Smirnov (*C. A.* 16, 1747), i. e. 2 maltose or 1 maltose and 1 gentiobiose union, give values (216° and 87°, resp.) which, even if the rule of optical superposition holds only approx., are in no agreement at all with the value found exptly. (137°). The elementary substance of cellulose would be expected to be wholly or almost wholly inactive, a condition fulfilled neither by Karrer's "cellosan" formula, nor by Pringsheim's cellobiose anhydride formula if it be assumed that the configuration is sym.; if configurative asymmetry

(i. e. an α - and a β -glucosidic union) is assumed for the P. formula, it cannot be checked by calcn. as 5- α -glucosidoglucose is not yet known.

Configuration and degradation of ϵ -truxillic acid. X. R. STOERMER, JOH. NEUMÄRKER AND RUDOLF SCHMIDT. *Ber.* 58B, 2707-18(1925); cf. *C. A.* 19, 2825.—Since ϵ -truxillic acid (I) is obtained from all of the other truxillic acids by alkali fusion and does not form an anhydride, it was at first supposed to be a *trans*-acid but, for reasons briefly discussed in earlier papers, it is now assigned the *cis*-structure (as shown in the fig.). The efforts to obtain a monomol. anhydride have been renewed and although they failed, it has been possible to obtain the *imide* (II) and *phenylimide* (III). II, obtained in small yield by dry distn. of the NH_4 salt of I (the chief products of the reaction being mostly the diamide (IV) with somewhat less of the *amidic acid* (V)), is obtained much more satisfactorily by heating IV several hrs. with 75% ZnCl_2 in AcOH , while III is prepd. from the *amidic acid* (VI) with hot Ac_2O and NaOAc ; both can be hydrolyzed stepwise, through V and VI, resp., to I. All the theoretically possible *cis*- and *trans*-truxillic acids have therefore now been well characterized. The extraordinary stability of I is undoubtedly related to its perfectly sym. configuration; it is obtained by rearrangement from all of its isomers but cannot itself be rearranged into any of them. Derivs. substituted in only 1 or unsym. in both CO_2H groups tend to assume a sym. structure when heated in dry state or in suitable solvents; thus, V forms II, I and IV at high temps., VI with Ac_2O alone gives I and the dianilide (VII), the *amidine amide* (VIII) with AcOH gives IV and VII. The stability of the anhydrides of the 3 *cis*-acids increases with the no. of Ph groups near the CO_2H groups; that of the *peri*-acid is formed on mere fusion of the acid and is not decompd. by boiling AcOH , that of the γ -acid is obtained from the acid only by heating with Ac_2O and is hydrolyzed by boiling AcOH , while that of I cannot be prepd. even in this way. Likewise II is hydrolyzed, with extreme ease (cold dil. Na_2CO_3) while the amide of the γ -acid requires several hrs'. boiling; even dry NH_3 in anhyd. solvents converts II into IV. V was converted successively into 2,4-diphenyl-3-aminocyclobutane-1-carboxylic acid (IX) (by the Hofmann degradation) and then, with progressively diminishing yields, into the 3-hydroxy- (X) and 3-halogen acids and finally reduced and sapond. The greatest difficulty in this process was the continuous appearance of unsatd. derivs. (presumably of a cyclobutenecarboxylic acid) which stubbornly resisted hydrogenation. The final satd. cyclic acid (XI) was not identical with the distyranic acid (XII), m. 176° . The structure of I was further confirmed by heating I with 3 parts piperidine 4 hrs. at 160° ; this gave mainly ϵ -truxillpiperididic acid (XIII), m. 220° , which is not resolvable into optical antipodes (*Me* ester, m. 91° ; *Et* ester, m. 110°), together with about 20% of the *dipiperidide*, m. 189° , hydrolyzed to XIII by short boiling (up to 20 min.) with concd. alc. KOH, to I by long boiling. The truxillic esters with arylmagnesium halides readily yield tertiary alcs. α -Tetraphenyltruxilldiol (11.5 g. from 15 g. of the di-*Et* ester of the α -acid in C_6H_6 with PhMgBr in Et_2O), m. 262° ; γ isomer, m. 219° ; ϵ -compd., also m. 219° but strongly depresses the m. p. of the γ -diol, forms a *dibenzozate*, m. 169° . ϵ -Tetraethyltruxilldiol, from the ester of I with EtMgBr , m. 201° . The α -diol is not converted into an anhydride by dehydrating agents, while the γ -diol in C_6H_6 with P_2O_5 on the H_2O bath yields a γ -oxide, $\text{C}_{12}\text{H}_{10}\text{O}$, cryst. powder, m. 208° , and 5 g. of the ϵ -diol, gently heated 10 min. at most with ZnCl_2 , gives 4.5 g. of the ϵ -oxide, m. 170° ; hydrolysis back to the ϵ -diol is rendered difficult by the numerous tarry by-products which are formed; it was effected once with hot alc. alkali under pressure and also with AcOH satd. with HBr (the product in this case being the dibromide of the diol) but not with PCl_5 . The ϵ -diol dihalides are obtained almost quant. by gently warming the diol with the calcd. amt. of PCl_5 or PBr_3 0.5-2.0 hrs in CCl_4 ; the *dichloride*, m. $175-6^\circ$, is gradually decompd. by boiling H_2O , while the *dibromide*, m. 126° , is more stable but is also slowly decompd. by hot alc.; the dichloride gives the oxide on mere boiling in AcOH . The following homologs of the above compds. have been prepd. by Lengfeld (*Diss. Rostock, 1925*): ϵ -Tetra-*p*-tolyltruxilldiol, m. 232° ; anhydride, m. 195° ; *dichloride*, m. 155° ; *dibromide*, m. 112° . *o*-Tolyldiol, m. 219° ; anhydride, m. 146° . *p*-Amisylldiol, m. 224° ; anhydride, m. 84° . *o*-Phenetyldiol, m. 174° ; anhydride, m. 92° . II (75% from IV), m. 198° , mol. wt. in boiling Me_2CO 265-8, gives with PhNH_2 at $170-80^\circ$ VIII, m. 222° ; *Na* salt of II; *K* salt, m. 224° . With EtBr in alc. at $160-70^\circ$ these salts are merely converted to the di-*Et* ester of II; the ϵ -ethylimide, m. 144° , was finally obtained by refluxing II in abs. alc. with EtBr , ignited K_2CO_3 , a little KI and a trace of "Naturkupfer." V, m. 213° . *Me* ester, m. 145° ; *Et* ester, m. $140-1^\circ$. VI, m. 239° , is obtained in good yield from I heated 20 min. at

210-220° with 1 mol. PhNH₂; Na salt, gelatinous; Ca salt, crystals more difficultly sol. in hot than in cold H₂O; Me ester, m. 157°. **III** (25% from **VI** with 5 parts Ac₂O and 2 parts NaOAc at 145-50°), m. 252°, mol. wt. in boiling CHCl₃ 372. **IX** (yield, about 80%), rodlets with MeOH of crystn. which is lost in the air or *in vacuo*, m. 188° (decompn.); Me ester, does not cryst.; HCl salt, m. 244° (decompn.). **X**, from the ester of **IX** treated in cold dil. H₂SO₄ with NaNO₂ and sapond. with cold alc. KOH, crystals with 2H₂O (lost *in vacuo* at 30-5°), m., anhyd., 166-7° (decompn.). 2,4-Diphenylcyclobutane-1-carboxylic acid, obtained in very small amt. by treating the Me ester of **X** with hot Et₂O with PCl₅, reducing the product with concd. HI, Zn dust and red P on the H₂O bath and sapon. with cold alc. KOH, m. around 172°, strongly depresses the m. p. of **XII**. **XI**. γ -Truxillic acid. R. STORMER AND FR. FRETWURST. *Ibid* 2718-25. The configuration of γ -truxillic acid (**I**) (*cis*-acid, with both CO₂H and 1 Ph group on the same side of the ring plane) has been further confirmed by the resolution of the amidic acid (**II**) into optical antipodes and regeneration of **I** by cautious hydrolysis of the *d*-**II**. **II** differs in some characteristic respects from the anilidic acids; it is completely hydrolyzed to **I** by long boiling with 15% HCl; aq. KOH also hydrolyzes it but yields chiefly the α -acid (**III**) and as **I** itself shows not the slightest tendency to undergo such a rearrangement under these conditions it must be the **II** which rearranges before being hydrolyzed; with boiling alc. KOH, **II** gives very little **III**, some unchanged **II** and considerable amts. of the α -amidic acid (**V**) while **V** under the same conditions partly rearranges into **II**. The α -diamide (**VI**) with alc. KOH in an autoclave at 120° gives an apparently homogeneous product (**VII**) which, however, can be sepd. into **II** and **V** by tedious fractionation from alc. while in a sealed tube in a bomb oven at the same temp. (in which the pressure and probably the inside temp. are higher) it is completely saponified and rearranges almost wholly into the ϵ -acid; **II** under the same conditions gives only **III**. On fusion, **II** slowly loses H₂O and changes into the *imide* (**VIII**), which is best obtained by long heating of the NH₄ salt of **II** (in this case some **V** is also formed as by-product but no **III** or **VI**; in sealed tubes at 180-200°, a small amt. of **VI** is obtained but still no **III**). With Ac₂O-NaOAc **II** likewise gives some **VIII** but in poor yield together with considerable γ -truxillacetamidic acid (**IX**), which becomes the chief product when the NaOAc is omitted. The ring in **VIII** is ruptured by Na₂CO₃ only on long boiling, by excess of cold alc. KOH in 24 hrs. The ethylamidic acid (**X**) with HNO₂ yields a *NO* deriv. (**XI**) which with hot Na₂CO₃ decomps. completely into N₂CHMe and **I**, a reaction which can be applied to the anilidic acids and permits of the hydrolysis of the substituted amidic acids without any rearrangement. **II**, obtained almost quantitatively from the anhydride and concd. NH₄OH on the H₂O bath, m. 240° (loss of H₂O); Me ester, m. 154°; Et ester, m. 135-8°. The resolution of **II** into its optical antipodes is effected with morphine in alc.; the difficultly sol. *l*-salt, m. 183° (decompn.); *l*-acid, m. 258-9° (loss of H₂O) (mixed m. p. with *dl*-**II**, 247-8°), [α]_D²⁰ -11.05° (0.0706 g. in 10 cc. AcOH) soly. in AcOH at 21° 0.66% (*dl*-acid 1.49%). Salt of *d*-acid, m. 89-90°; free acid, m. 258-9°. Me ester of *l*-acid, m. 153-4° (mixed m. p. with the *d*-ester 139-45°) [α]_D²⁰ 8.55° (0.3764 g. in 10 cc. alc.); Et ester of *d*-acid, m. 168-9°, [α]_D²⁰ -12.78° (0.2031 g. in 10 cc. Me₂CO). **VIII** (75% from the NH₄ salt of **II** at 240-50°), m. 208°. **IX**, m. 185°, hydrolyzed to **II** by boiling 10% alc. KOH, to **I** by hot 15% HCl. K and Na salts of **VIII**, from **VIII** in the least possible amt. of alc. with 1 mol. alc. KOH and much Et₂O, silvery leaflets. Phenylimide of **I**, from **VIII**, PhBr, ignited K₂CO₃, "Naturkupper" and KI in boiling PhNO₂, m. 194°. Ethylimide, m. 142°, hydrolyzed by short boiling with alc. KOH to **X** (also obtained from the anhydride and NH₄Et in alc. on the H₂O bath), m. 217°, converted into the ethylimide by Ac₂O-NaOAc at 160°. **XI**, faintly yellow, m. 172-3° (violent decompn.), deflagrates on dry heating. Nitroso-anilidic acid, suddenly decomps. 129-30°, decompd. by short boiling with concd. HCl into the anilidic acid, by 25% KOH into **I**. C. A. R.

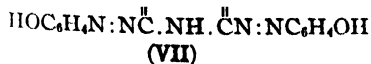

Catalysis and change in form of molecules. N. D. ZELINSKII (WITH MRS I. N. TRTZ). *Ber.* 58B, 2755-63(1925).—As the result on the one hand of his work on hydrogenation and dehydrogenation catalysis and, on the other, of observations made on certain transformations which occur under the influence of contact action (see, e. g., C. A. 19, 2333), Z. is convinced that intermediate chem. compds. are not a *conditio sine qua non* of catalytic processes but (cf. also Mendelyev, *J. Russ. Phys.-Chem. Soc.* 18, 8(1886); Raschig, *Z. angew. Chem.* 19, 2049(1906); Bodenstein, *C. A.* 19, 924) that in such processes are involved changes in the motions of the mols. and atoms resulting from changes in form of the system produced by contact action; in the present paper are given further instances in support of his view. Cyclohexylcyclopentane (**I**) on catalytic dehydrogenation is attacked in both nuclei simultaneously, the product being not the expected phenylcyclopentane (**II**) but a compd. C₁₁H₁₈ (**III**), which, however,

cannot be phenylcyclopentadiene, as it has a completely satd. character; the cyclopentamethylene ring (IV) must, therefore, have suffered a deep-seated deformation during the dehydrogenation. II cannot be dehydrogenated with either palladinized or platinized asbestos, even with the assistance of platinized active charcoal; in order to be capable of undergoing dehydrogenation IV must, therefore, be combined with a hexahydrophenyl (V), not with a Ph residue; as V easily splits off H it forces IV to do the same. In 1-cyclohexyl-3-methylcyclopentane (VI), V, losing some of its H, forces the methylcyclopentyl ring to lose some also but the latter residue at the same time undergoes a deep-seated rearrangement, the sole product being Ph₂. I, obtained by treating cyclopentanone with C₆H₁₁MgBr, boiling the resulting pentanol, b₁₀ 115–8°, with aq. (CO₂H)₂ or treating it with KHSO₄ and reducing the unsatd. hydrocarbon, b. 226–8°, with H and Pd-asbestos at 160°, b. 225–7°, d₄²¹ 0.8813, n_D²¹ 1.4767 (it is also obtained by treating the pentanol with AcOH satd. at 0° with HI and then warming with Zn

dust). III, which is provisionally assigned the structure $\text{PhCH} \begin{array}{c} \diagup \text{CH} \cdot \text{CH} \cdot \\ \diagdown \text{CH} \cdot \text{CH} \end{array}$, is obtained

in 3 g. yield from 8.5 cc. I passed 3 times at the rate of 1 drop per min. through a 7 × 400-mm. tube filled with 30% palladinized asbestos at 300–5°; it m. 69.4°, b. 248–9°, does not react with Br, KMnO₄, picric acid or K in boiling C₆H₆. Phenylcyclopentanol, from cyclopentanone and PhMgBr, b₁₈ 132–3°, d₄¹⁹ 1.0609, n_D¹⁹ 1.5472, gives with HI-AcOH II, b. 215–7°, d₄¹⁹ 0.9503, n_D¹⁹ 1.5305. VI (8 g. from 16 g. of the pentanol, b₁₆ 125°, with HI-AcOH), b. 231–3°, d₄¹⁷ 0.8902, n_D¹⁷ 1.4787. C. A. R.

The tautomeric form of hydroxyphenylazocarboxamide. A. PIERONI, *Gazz. chim. ital.* 55, 793–804 (1925).—In continuation of earlier work (C. A. 17, 1439; 18, 3177, 3188), P. has undertaken the study of *p*-hydroxyphenylazocarboxamide (I). 100 g. pure *p*-HOC₆H₄NH₂ was heated with 100 cc. HCl (d. 1.45) and some pieces of Sn. After a few hrs. the soln. was dild. with H₂O, boiled and filtered. Sn was removed with H₂S and the filtrate was concd. in a stream of H₂S. On cooling white *p*-H₂NC₆H₄OH·HCl (II) seps. 35 g. II in 100 cc. EtOH + 13 cc. concd. H₂SO₄ was diazotized with 20 g. EtONO₂ at 10–1° for 2 hrs. with agitation. The mixt. was then cooled to 0° and 100 cc. 40% KCN was added slowly. Concd. HCl was added drop by drop, keeping the temp. below 0°, and the nitrite (III), HOC₆H₄N:NCN, m. 117° (decompn.), sepd. A satd. Et₂O soln. of dry III treated with HCl gas at 15–6° seps. I. A satd. EtOH soln. of I made alk. with KOH gives a ppt. which treated in H₂O with CO₂ gives I, red, m. 172°. To 14 g. quinone in hot EtOH was added 12 g. H₂NCONHNH₂·HCl. The mixt. solidified. The calcd. amt. of NaOAc necessary to eliminate HCl was added. The ppt. was filtered off and washed with the min. of H₂O. The *p*-quinone semicarbazone (IV) obtained was dissolved in EtOH, pptd. with KOH + Et₂O; the K salt was decompd. with CO₂ as above and gave IV, yellow, which becomes red at 120° and m. 172° (decompn.). In this way unstable IV, O:C₆H₄:NNHCONH₂, gives the more stable HOC₆H₄N:NCNH₂ (I). In glacial AcOH IV is more sol. than I. 6 g. I suspended in a little glacial AcOH with 12 cc. perhydrol and then kept at 40° for several days still contained a little H₂O₂. The AcOH was evapd. in the air and impure phenolazoxycarboxamide (V), HOC₆H₄N(O):NCONH₂, sepd.; from hot H₂O V seps. as yellow needles, m. 153° (decompn.). In aq. alk. soln. V with β-naphthol, like other azoxyamides, gives the corresponding *p*-hydroxybenzenecazonaphthol (VI), m. 194°. VI in glacial AcOH with the calcd. amt. of Br₂, then AcONa to neutralize the HBr and H₂O to ppt. gave *p*-hydroxydibromophenylazoxycarboxamide, red, m. 232°. Both I and its di-Br deriv. react with pyrole in alk. medium, giving VII and VIII, resp., which will be fully described in a later paper.

E. J. WITZEMANN

Coloring substances derived from thiocarbodibenzidine. II. G. ROSSI AND B. CRECHETTI, *Gazz. chim. ital.* 55, 872–5 (1925).—In a preceding paper (C. A. 19, 2657) R. and C. described thiocarbodibenzidine (I), (H₂NC₆H₄C₆H₄NH)₂CS₂. I diazotized with HNO₃ in HCl gives tetrazothiocarbodibenzidine chloride (II) S:C(NHC₆H₄N)₂Cl. The soln. of II was treated with the calcd. amt. of PhONa in NaOH. The brown soln. was neutralized with HCl and gave a ppt. which was sol. in dil. Na₂CO₃.

The [diphenolazo]thiocarbodibenzidine, $S:C(NHC_6H_4C_6H_4N:NC_6H_4OH)_2$, is a direct dye for cotton, silk and wool. The corresponding (*di-β-naphtholazo*) compd., obtained with $C_{10}H_7ONa$, is sol. in xylene, insol. in alkalis and dil. HCl. E. J. W.

Stereoisomers of chloriodoethylene. H. VAN DE WALLER AND A. HENNE. *Bull. soc. chim. Belg.* 34, 399-410(1925).—See C. A. 20, 1050. W. B. PLUMMER

Bromophenols. VII. Bromine substitution products of hydroquinol. MORITZ KOHN AND L. W. GUTTMANN. *Monatsh.* 45, 573-88(1925); cf. C. A. 19, 1700.—Heating Habermann's dibromohydroquinol di-Me ether (*Ber.* 11, 1034) with fuming HBr and AcOH gives 2,5-dibromohydroquinol (I), showing that H.'s ether is 1,4-dimethoxy-2,5-dibromobenzene (II). This was further confirmed by its synthesis through methylation of I. Fuming HNO_3 , acting on II, gives 2,5-dibromoquinone, m. 188-9°. *Tribromohydroquinol di-Me ether*, m. 101-3°; with fuming HNO_3 it gives tetrabromoquinone (bromanil) (III). 2,6-Dibromohydroquinol di-Me ether (IV), m. 56°; nitration with fuming HNO_3 gives the 3,5-dinitro deriv. (V), pale yellow, m. 150-1°. *Crystallographic data* by K. Hlawatsch are given for I-V and for 2,6-dibromohydroquinol. **VIII. Bromo- and bromonitroresorcinols.** MORITZ KOHN AND GEORG LÖFF. *Ibid* 589-95.— $m-C_6H_4(OH)_2$ and Br in CCl_4 give the 4,6- Br_2 deriv., m. 110-2° (Zehenter, *Monatsh.* 8, 296 (1887)), whose di-Me ether (VI), m. 138°, is identical with Hönig's compd. obtained from Br and $m-C_6H_4(OMe)_2$ (*Ber.* 11, 1041(1878)). Further bromination of VI gives the 2,4,6- Br_3 deriv., m. 60-1° (Torrey and Hunter, *C. A.* 5, 1400, give 68-9°); with fuming HBr and AcOH it gives 2,4,6-tribromoresorcinol, m. 111°. Me_2SO_4 and KOH contg. a little NaSH give the di-Me ether, m. 62°, while bromination of $m-MeOC_6H_4OH$ and methylation give an ether, m. 69°. 3-Hydroxy-1-methoxy-2,6-dibromo-4-nitrobenzene, deep yellow, m. 122°, from the 2,4,6- Br_3 deriv. and KNO_3 in AcOH; the K and Na salts are yellow, the Ag salt, red. With HBr and AcOH it gives 2,6-dibromo-4-nitroresorcinol, m. 146°. **IX. Bromo- and bromonitrophenols.** M. KOHN AND SALOMEA STRASSMANN. *Ibid* 597-603.—Soln. of tetrabromoanisole in fuming HNO_3 gives 1-methoxy-2,3,4,6-tetrabromo-5-nitrobenzene, m. 122°, which is demethylated by HBr in AcOH, giving 2,3,4,6,5- $Br_4(O_2N)C_6OH$, m. 162°. Nitration of tetrabromophenyl acetate ($H_2SO_4 + HNO_3$) gives the yellow 2,3,6-tribromo-5-nitroquinone, m. 285°. Tribromoanisole gives 1-methoxy-2,4,6-tribromo-3,5-dinitrobenzene, m. 148°, which is demethylated by HBr, giving 2,4,6-tribromo-3,5-dinitrophenol, m. 196°. The product from the bromination and methylation of $m-BrC_6H_4OH$ is 3,4,6- or 2,3,4-tribromo-6-nitroanisole, m. 67°, which, with fuming HNO_3 , gives 2-nitro-3,4,6-tribromo- or 2,3,4-tribromo-6-nitroanisole, m. 105°. **X. Chloronitro ether and bromonitro ether of hydroquinol and toluhydroquinol and the mobility of the halogen atom in the same.** M. KOHN AND RICHARD MARBERGER. *Ibid* 649-62.—2,6-Dichloro-3,5-dinitrohydroquinol di-Me ether (VII), m. 121-3°, prepd. as V; extensive crystallographic data are given. Boiled with C_6H_5N for about 20 min., there results the mono-Me ether, m. 97° (crystallographic data). 1-Methyl-2,5-dimethoxy-3-bromo-4,6-dinitrobenzene, m. 124-6°; C_6H_5N gives the mono-Me ether, light yellow, m. 86°. 4-Methoxy-3,5-dibromo-2,6-dinitrophenol, S-yellow, m. 135-7°. V, heated with 40 mols. $PhNH_2$ until boiling begins, gives 4-methoxy-2,6-dinitro-3,5-dianilinophenol, dark red, m. 181° (decompn.); it also results from VII and 30 mols. $PhNH_2$. 1-Methyl-6-methoxy-2,4-dinitro-3-hydroxy-5-anilino-benzene, dark red, m. 138-9°. **XI. Bromination of hydroquinol monomethyl ether and of nitrohydroquinol dimethyl ether.** M. KOHN AND SARA GRUN. *Ibid* 663-7.— $p-MeOC_6H_4OH$, rubbed with excess Br, gives 1-methoxy-4-hydroxy-2,3,5-tribromobenzene, m. 145°; also obtained in CCl_4 soln. KNO_3 in AcOH gives a nitrodibromo deriv., m. 170° (decompn.), yields red alk. salts and a dark purple Ag salt. The action of 6 mols. Br upon $O_2NC_6H_4(OMe)_2$ gives tetrabromohydroquinol di-Me ether, m. 190-1°, also obtained by methylating the tetrabromohydroquinol from bromanil. C. J. W.

The alkylmethylglycerols. RAYMOND DELABY AND GEORGES MOREL. *Bull. soc. chim.* 39, 220-30(1926).—See C. A. 19, 2326. E. H.

Monomethyl ether of styphnic acid and a new trinitroguaiacol, 2-hydroxy-1-methoxy-3,4,5-trinitrobenzene. MORITZ KOHN AND GEORG LÖFF. *Monatsh.* 45, 605-15(1925).—1,3,2,4,6-(MeO) $_5C_6H(NO_2)_3$, obtained in 50% yields from 25 g. $m-C_6H_4(OMe)_2$ in 6 vols. concd. H_2SO_4 treated with a mixt. of 150 cc. fuming HNO_3 and 150 cc. concd. H_2SO_4 with cooling, finally adding 50 cc. HNO_3 , gives with C_6H_5N the *N*-methylpyridinium salt of styphnic acid Me ether, yellow, m. 131-2°; the *N*-methylquinolinium salt, yellow, m. 151°. Decompn. of these salts with dil. HCl gives styphnic acid Me ether, pale yellow, m. 80°; C_6H_5N salt, yellow, decomps. about 140-5°; quinoline salt, yellow, decomps. 165-174°; heating with KOH gives the free acid, 1,2,3,4,5-(MeO) $_5C_6H(NO_2)_3$, heated with AcOH-HBr, gives 2-methoxy-4,5,6-trinitrophenol (2-hydroxy-1-methoxy-3,4,5-trinitrobenzene), light yellow, m. 143-9° (some decompn.);

C_6H_5N salt, dark yellow, m. 158° (decomps.); quinoline salt, dark yellow m. 201° (decompn.); Bz deriv., m. 146° ; *N*-methylpyridinium salt, deep red, m. 120° ; *N*-methylquinolinium salt, bright red, m. $161-3^\circ$. C. J. WEST

Mono- and dimethoxypicric acids and their chlorides. H. H. SCHLUBACH AND FRITZ MERGENTHALER. Ber. 58B, 2732-6(1925).—The present incomplete results are published now because of the appearance of the paper of Hodgson and Moore (C. A. 19, 2937). In attempting to explain the mechanism of the Wurtz-Fittig synthesis the possible intermediate formation of free Ph radicals has been suggested (C. A. 17, 1417), but there seems to be very little hope of being able to isolate Ph itself. S. and M. thought, however, that by suitably substituting the H atoms in the Ph group its properties might be so altered that the free radical might be isolated and as the Cl in PhCl is rendered increasingly labile by the successive introduction of NO_2 groups in positions 2, 4 and 6, just as that in MeCl is by the introduction of aryl groups, they tested $(O_2N)_3C_6H_2C_6H_2(NO_2)_3$ (I) for any possible indications of dissociation into radicals but mol. wt. detns. gave no evidence of any such dissociation. The remaining H atoms in picric acid (II) and picryl chloride (III) were then replaced by 1 and 2 MeO groups and the cond. of the 4 resulting compds. compared with that of II and III; the results showed that introduction of the MeO groups does not increase but, in fact, decreases the cond., and, moreover, the 2 MeO-substituted chlorides cannot any longer be converted into the corresponding Ph_2 derivs. by the Ullmann method. Mol. wt. of I (0.4818, 0.7688 and 0.9676 g., resp., in 32 g. boiling $PhNO_2$), 359, 430, 399 (calcd., 424). 5,2,4,6-MeO $(O_2N)_3C_6H_2OH$ (IV), by a modification (acidifying with dry HCl gas instead of aq. acid) of Blanksma's method (Rec. trav. chim. 21, 254(1902)) is obtained in 62% yield and in pure form, m. 87.5° ; it cannot be converted with PCl_5 into 3-chloro-2,4,6-trinitroanisole (methoxypicryl chloride) (V), m. 86° , which was accordingly prepd. (yield, 61.5%) from *m*- ClC_6H_4OH and $HNO_3-H_2SO_4$. 3,5- $(O_2N)_2C_6H_3OMe$ with $AlCl_3$ at 130° gave 80% $(O_2N)_2C_6H_3OH$, m. $123-4^\circ$, which in hot concd. H_2SO_4 with $HNO_3-H_2SO_4$ yielded 52% $(O_2N)_3C_6H_2OH$, and this by B.'s method gave 70% dimethoxypicric acid (VI), S-yellow, m. 76.5° . 1-Chloro-3,5-dimethoxy-2,4-dinitrobenzene (34.7% from $(O_2N)_2C_6H_3Cl$ in C_6H_6 with Na in MeOH), m. 220° , gives in HNO_3 with fuming H_2SO_4 83.6% of 5-chloro-2,4,6-trinitroresorcinol di-Me ether (dimethoxypicryl chloride) (VII), m. 88.5° . Cond. ($K_p \cdot 10^4$) in MeOH for ν 64,000, 128,000, 250,000, resp.: II (at 24.3°) 3.62, 2.37, 1.624; IV (24.52°) 2.71, 1.88, 1.225; VI (24.56°) 1.716, 1.555, 0.77; III (24.3°) 1.007, 0.705, —. C. A. R.

Action of chlorosulfonic acid upon phenols. I. Derivatives of the three cresols and phenol. JAKOB POLLAK, ERICH GEBAUER-FÜLNEGG AND EUGEN RIESZ. Monatsh. 46, 383-97(1926).—At room temp. *o*- MeC_6H_4OH and $ClSO_3H$, either in equiv. amts. or with excess of acid, give 2-hydroxytoluene-3,5-disulfonyl chloride (*o*-cresol-4,6-disulfonyl chloride), m. $85-6^\circ$; $FeCl_3$ gives a violet color. *m*- MeC_6H_4OH gives *m*-cresol-4,6-disulfonyl chloride (?), m. $84-9^\circ$; $FeCl_3$ gives a violet color. If the equiv. amt. of $ClSO_3H$ is added to 5 g. *m*- MeC_6H_4OH , there is formed principally *m*-cresolsulfonic acid, but also 0.2 g. di-*m*-cresyl sulfate, m. 119° ; $FeCl_3$ gives no color. The *p*-cresoldisulfonyl chloride, m. 105° . $PhOH$ (10 g.) gives 3 g. phenol-2,4-disulfonyl chloride, m. 89° , gives a red violet color with $FeCl_3$. Heating 10 g. *o*- MeC_6H_4OH and 100 g. $ClSO_3H$ 3 hrs. at 110° gives 17-8 g. *o*-methylphenylene-*o*-sulfonylide-*p,p'*-disulfonyl chloride, decomps. 280° , is stable in boiling H_2O or EtOH, is saponif. by EtOH-KOH and then gives a deep red-violet color with $FeCl_3$. Heating the 2 reacting compds. 6 hrs. at 150° gives 4 g. of the chloride and the free acid, analyzed as the Ba salt, yellow, which crysts. with 4.5 mols. H_2O . *m*- MeC_6H_4OH (10 g.) and 100 g. $ClSO_3H$ at 110° for 1.25 hrs. give 9 g. of *m*-cresolsulfonylide disulfonyl chloride, decomps. 290° ; heating 6 hrs. at $130-40^\circ$ and pouring into concd. HCl gives 12 g. *m*-cresol-2,4,6-trisulfonyl chloride, m. 151° , saponif. by hot H_2O ; the amide decomps. at 290° ; pouring the above reaction product into H_2O gives the free acid, analyzed as the Pb salt. *p*- MeC_6H_4OH likewise gives a *p*-cresolsulfonylide disulfonyl chloride, decomps. at 280° . $PhOH$ and $ClSO_3H$ give after 4-5 hrs. at $130-40^\circ$ phenol-2,4,6-trisulfonyl chloride, m. 193° ; a sulfonylide was not obtained. C. J. WEST

Dehydration of benzyl alcohol by the xanthate method. S. S. NAMEYKIN AND D. KURSANOV. J. prakt. Chem. 112, 164-8(1926).—Me benzyl xanthate, m. 29° , in 60% yield from 54 g. $PhCH_2OH$ in 35 g. $C_6H_5Me_2$ and the theoretical amt. of Na, 88 g. CS_2 , followed by treatment with Me_2SO_4 ; Et ester, b.p. $170-1^\circ$, does not solidify at -20° . EtOH- NH_3 gives 75% of the amide, m. $61.5-2^\circ$. Heating 23 g. of the Me ester at $180-350^\circ$ gives more than 5 g. stilbene and a compd. $C_{22}H_{20}S$, light yellow, m. $184-5^\circ$, mol. wt. in boiling C_6H_6 , 392, 399. C. J. WEST

The effect of various purification methods on xylene as solvent for catalytic reduc-

tions. FRITZ ZETZSCHE and OLGA ARND. *Helvetica Chim. Acta* 9, 173-7(1926).—The value of various hydrocarbons as solvents in the reduction of acid chlorides to aldehydes varies with their purity. The aldehyde-titer may be used as an index of their value. The impurities may (1) inactivate the catalyst; (2) allow a satisfactory reduction to aldehyde to take place; (3) the reduction goes past the aldehyde stage. To (1) belong most technical toluene, xylene, etc., and to (3) belong mostly the pure manufactured hydrocarbons. The latter class may be controlled by regulators. The reduction of BzCl was studied, the object being to convert a solvent of titer -0 into one of $+0$, and if possible to make the solvent inactive catalytically. Washing solvents, e. g., xylene, with concd. H_2SO_4 20-25 times accomplishes this, but the loss is great. Distn. will not work. Treatment with POCl_3 seems quite satisfactory, although the solvent so obtained is not entirely inactive catalytically. Of a series of other substances with which xylene was treated to render it catalytically neutral (Na-Hg, Cu, $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$, H_3PO_4 , animal charcoal, HCl , AlCl_3 , and quinoline-S) only anhyd. AlCl_3 was satisfactory. One treatment with this is equiv. to 12 washings with concd. H_2SO_4 . Both POCl_3 and AlCl_3 give solvents for catalytic reductions to aldehydes, which are usually satisfactory. E. H. VOLWILER

Usefulness of various solvents for the catalytic aldehyde synthesis from acid chlorides. FRITZ ZETZSCHE, FLORIAN ENDERLIN, CHRISTIAN FLÜTSCH and ERNEST MENZI. *Helvetica Chim. Acta* 9, 177-81(1926).—The use of aromatic hydrocarbons as solvents for the synthesis of aldehydes from acid chlorides is often limited by the insoly. of the reactants or products, and by the time required for the reduction. The solvent should be readily manipulated, purified, and regulated. BzCl was reduced in a large no. of solvents. The titer was first detd. for the solvent, usually at the b. p., then the solvent distd. and washed, and finally a regulator (quinoline-S) added to give a max. yield of aldehyde. The following were tried:— CHCl_3 , CCl_4 , $\text{C}_6\text{H}_5\text{N}$, quinoline, $\text{C}_2\text{H}_5\text{Cl}$, tetralin, decalin, PhCl , PhBr , PhCCl_3 , AmOAc , hexalin acetate, EtOBz , di-Et phthalate, anisole, phenetole, Ac_2O , turpentine and PhNO_2 . Tetralin, decalin, anisole and turpentine were promising. The 1st two resemble the aromatic hydrocarbons, but need not be so painstakingly purified. Addn. of 3 mg. quinoline-S as a regulator gave 82% of BzH from BzCl in 2 hrs. with tetralin, and 86% with decalin, at 180° . Both solvents had been twice distd. Anisole and turpentine gave similar results. All these solvents gave approx. twice the speed of reduction as with the usual aromatic hydrocarbon solvents. Ac_2O as a solvent gave with BzCl a good yield of Bz_2O , so that this may be used as a method of prepn. of anhydrides. F. H. V.

The action of ultra-violet rays on aldehydes. Hexahydrobenzaldehyde, phenylacetaldehyde and hydrocinnamaldehyde. ADOLF FRANKE and FRIEDRICH SIGMUND. *Monatsh.* 46, 61-74(1925).—Previous expts. show that ultra-violet light decomps. aliphatic aldehydes, RCHO , into CO and RH (cf. *C. A.* 6, 2074; 7, 2543). BzH does not undergo this kind of a decompn. (cf. *C. A.* 5, 2024). R. and S. find that $\text{C}_6\text{H}_7\text{CHO}$ yields CO , whereas PhCH_2CHO and $\text{PhCH}_2\text{CH}_2\text{CHO}$ do not. A partial valence from the unsatd. benzene ring evidently joins to the CHO group and prevents its decompn. Whether the CHO is in the β - or γ -position makes no difference in this inhibition. Decompn. into CO and hydrocarbon does not necessarily accompany polymerization to a trimer, e. g., in PhCH_2CHO . $\text{PhCH}_2\text{C}(\text{CH}_2\text{OH})_3$ was prepd. by condensing PhCH_2CHO with HCHO and alc. KOH . D. S. VILLARS

Chemical isomerism of the three *cis*-cinnamic acids. A reply to Mr. W. K. de Jong. HANS STOBBE. *Ber.* 58B, 2620-6(1925).—Cf. de J., *C. A.* 13, 3149. C. A. R.

Action of organic acids on beryllium carbonate. S. KINHORN. *Bul. soc. chim. Roumanie* 7, 100-1(1925).—Be acetylsalicylate, prepd. by neutralizing hot aq. $o\text{-AcO-C}_6\text{H}_4\text{CO}_2\text{H}$ by gradual addn. of a considerable excess of BeCO_3 with stirring, has a compn. corresponding to $(\text{AcOC}_6\text{H}_4\text{CO}_2\text{Be})_2\text{O}$, showing that it is formed by condensation of 2 mols. of $o\text{-AcOC}_6\text{H}_4\text{CO}_2\text{H}$ with elimination of 1 mol. H_2O . It is insol. in Et_2O , C_6H_6 , C_7H_8 , ligroin, CS_2 , CHCl_3 , NH_4OH , etc. It is sol. in mineral acids only when heated, except HCl , in which it is insol. Aq. solns. of phenylacetic, gallic and tannic acids dissolve only very small quantities of BeCO_3 on boiling, with evolution of CO_2 . Sebatic, mucic and hippuric acids do not attack BeCO_3 . Thioacetic acids and aq. solns. of $o\text{-HSC}_6\text{H}_4\text{CO}_2\text{H}$ dissolve considerable amts. of BeCO_3 , but the corresponding salts could not be isolated; thioacetic acid gives $\text{Be}(\text{OAc})_2$ with evolution of H_2S , and $\text{HSC}_6\text{H}_4\text{CO}_2\text{H}$ gives a thick, gummy, uncrystallizable sirup. A. PAPINEAU-COUTURE

2-Mercapto-5-methylbenzoic acid. F. KROLLPFIEFFER with H. SCHULTZE and E. SOMMERMEYER. *Ber.* 58B, 2698-701(1925).—The compd. (I) obtained by Arndt (*C. A.* 20, 197) by the decompn. of 2,2-dichloro-6-methylthiochromonol with H_2O ,

which he believes is 3,6-Me(HS)C₆H₃CO₂H is different from K.'s 5,2-Me(HS)-C₆H₃CO₂H (II), obtained by alk. degradation of 2,6-dimethyl-3-bromothiochromanone (III) (C. A. 20, 202), which in all its properties resembles the unsubstituted 2-HSC₆H₃CO₂H (IV). That I is no homolog of IV was proved in an attempt to oxidize it to the disulfide acid with alk. K₂Fe(CN)₆; no well-defined disulfide acid was obtained but CO was evolved on the addn. of the K₂Fe(CN)₆; furthermore, alkali fusion of I yielded 5-methylthionaphthenequinone. Both observations indicate that I has more C atoms than II, and A. must have been misled by an error in analysis; K., S. and S. find 15.56–15.61% S in I instead of the 19.1% given by A. Whether I is a 2,3,4-triketothiochroman, with which the above S content agrees, is left to A. to det. That the constitution assigned to II is correct has been established by synthesizing it from 5,2-Me(H₂N)C₆H₃CO₂H (V) and by converting it into 5-methyl-3-hydroxythionaphthene (VI). In connection with the statement of A. that dehydration with PCl₅ has hitherto proved to be the "only practicable way" for the prepn. of chromone (VII) from chromanone, attention is called to the work of v. Auwers (C. A. 14, 3633) who describes the prepn. of substituted chromones from the corresponding 3-bromochromanones by boiling with PhNMe₂, and K., S. and S. have prepd. VII itself from 3-bromochromanone by boiling both with PhNMe₂ and with C₆H₅N so that the difference in reactivity of the H atoms in position 2 of 3-bromothiochromanones and 3-bromochromanones alleged by A. does not exist. V (4.2 g.) diazotized in aq. H₂SO₄ with NaNO₂, then treated with SO₂ and with "Naturkuper C," gives 2 g. of the crude SO₂H acid which with Zn dust and HCl in alc. yields II, m. 155°, identical with the product obtained from III. With an excess of ClCH₂CO₂H in an equiv. amt. of aq. Na₂CO₃ II in NaOH gives on the H₂O bath *p*-tolylthioglycolic-o-carboxylic acid, m. 220° (decompn.) (yield, nearly quant.), 0.5 g. of which, with 5 g. NaOH and a little H₂O at 180°, yields 0.1 g. VI, m. 100°. I (1.5 g.) under the same conditions gives with ClCH₂CO₂H 0.5 g. of an acid, m. 226°, which on alk. fusion yields II.

Degradation of 2,2-dichlorothiochromonols. F. ARNDT. *Ber.* 58B, 2702(1925); cf. preceding abstr.—The error in the S detn. of the supposed Me(HS)C₆H₃CO₂H had been detected in A.'s lab., also that 3-bromochromanone can be converted into chromone by boiling with tertiary bases, but whereas long boiling is required to effect the latter conversion, only a few min. is required in the thiochromanone series. C. A. R.

Determination of unsaturated hydrocarbons in the presence of saturated and tricyclic hydrocarbons; the solution of the problem from the point of view of the dehydration of alcohols. S. S. NAMETKIN AND LYDIA BRYSSOVA. *J. prakt. Chem.* 112, 169–76(1926).—The method depends upon the discovery of Prileschaeff (C. A. 6, 2407) that Et₂O or CHCl₃ solns. of unsatd. hydrocarbons react quant. with BzO₂H; the excess BzO₂H reacts with KI and H₂SO₄ and the liberated I is titrated with Na₂S₂O₃. The reaction with menthene, limonene, tricyclene, fenchocyclene, α methylcamphene, bornylene and a mixt. of limonene and menthane is described. C. J. WEST

Isomeric carvomenthols from carvacrol. VINCENZO PAOLINI. *Gazz. chim. ital.* 55, 818–24(1925).—In previous work P. (Atti accad. Lincei 32, II, 134, 731) showed how

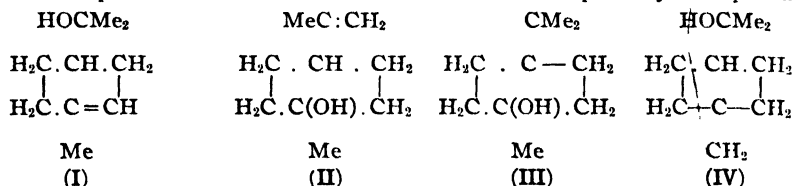

various carvomenthols (I) (menthan-2-ols), CH₂ $\overset{*}{\text{C}}\text{H}(\text{CHMe}_2) \text{CH}_2$ prepd. by various

authors are mixts. of 8 stereoisomers, arising from the 3 asym. C atoms, in unknown proportions. Several preps. of I have been characterized or sepd. by P.'s cold esterification process with C₆H₄(CO)₂O. Another mixt. of I can be obtained by reducing carvacrol (II) according to a modification of Brunel's method. The product contains about 50% of unchanged II. When the mixt. is agitated with 5% NaOH II is dissolved. 20 g. of I (a mixt. of α - and β -carvomenthol) in 500 cc. PhMe was treated with K. After decanting from the excess K the calcd. amt. of C₆H₄(CO)₂O suspended in PhMe was added. After 48 hrs. 700–800 cc. dil. KOH was added. From this soln. β -carvomenthol acid phthalate (III) (a mixt. of at least 2 phthalates) sepd. on adding dil. H₂SO₄. 10 g. III, m. 125°, in abs. EtOH was treated with the calcd. amt. of strychnine. After evapg. the EtOH the strychnine salt was dissolved in CCl₄ and on adding petroleum ether half of the salt sepd.; m. 148°, [α]_D –14.72°. 20 g. of this salt was dissolved in EtOH; excess HCl (d. 1.18) was added and then H₂O; *l*, β -carvomenthol acid phthalate, m. 125°, [α]_D –3.70°, sepd. This sapond. by EtOH-KOH gives *l*, β -carvomenthol, b. 218°, *d*₄ 0.9082, *n*_D¹⁵ 1.4610, [α]_D –1.81°. The liquid, from which the less sol. strychnine salt was sepd., was evapd. and converted with HCl into *d*, β -carvomenthol acid phthalate, m. 125°, [α]_D 3.77°. This sapond. with EtOH-KOH gave *d*, β -carvomenthol, b. 218°, *d*₄ 0.9081, *n*_D¹⁵ 1.461, [α]_D 1.79°. The acid phthalate sol. in cold petroleum

ether was converted into the *Ag salt*, m. 225°, but was recovered in the free state again as an oil. This treated as above gave *l,α-carvomenthol*, $[\alpha]_D -2.70^\circ$, and *α,α-carvomenthol*, $[\alpha]_D 2.20^\circ$. These products were sirupy and purification is probably not complete. From a summary of results obtained so far P. concludes that in the 4 papers published so far 6 of the 8 possible stereoisomers of I have been described. E. J. W.

Isomeric terpineols and the separation of α-terpineol into its optical antipodes. VINCENZO PAOLINI. *Gazz. chim. ital.* 55, 804-11 (1925).—Liquid com. terpineol (formed by the action of H_2SO_4 or dil. H_3PO_4 on terpene hydrate) is a mixt. of at least 3 isomeric alc., of which α-terpineol (I), m. 35°, β-terpineol (II), m. 32°, and γ-terpineol (III), are formed when H_3PO_4 is used (IV is the remaining unknown isomer). Various mixts. of these compds. are obtained and when individuals are sepd. they are optically in-

active. These compds. are so readily isomerized that the usual method of esterifying the alc. with $C_6H_4(CO)_2O$ and subsequent fractionation of the strychnine salt cannot be applied. In 1910 P. (*C. A.* 5, 3404) developed a modification of Haller's method by which he has sepd. the active isomers of tana-cetyl alc., linalool, sabinol, santalol and carvomenthol. The α-terpineol (I) used, b. 218°, m. 35°, and was optically inactive. 10 g. I in 200 cc. PhMe was treated with 4 g. K wire for 10-12 hrs. The soln. of the K alcoholate was decanted from the excess K and treated slowly with 9.6 g. $C_6H_4(CO)_2O$ in much PhMe. After 48 hrs. 400-500 cc. very dil. aq. KOH was added. The phthalic ether was taken up by the H_2O as the K salt; the soln. was acidified with H_2SO_4 and sepd. the acid phthalate. This was washed, dried and dissolved in abs. EtOH. The calcd. amt. of strychnine was then added and enough $CHCl_3$ to give complete soln. Presently the strychnine salt of the *l*-form (VI), $C_{11}H_{18}(CO_2C_{10}H_{17})(CO_2H \cdot C_2H_4N_2O_2)$, sepd.; recrystd. from iso-BuOH this m. 207°, $[\alpha]_D -40.80^\circ$. 50 g. pure VI was treated with $NH_3 \cdot H_2O$ on the H_2O bath; the strychnine was filtered off; the filtrate, acidified with H_2SO_4 , pptd. *l-α-terpineol acid phthalate*. This was sapond. with hot KOH-EtOH; the *l-terpineol*, removed by steam distn., b. 218°, m. 37-8°, $d_{15} 0.935$, $[\alpha]_D -98.20^\circ$. The mother liquor from VI was evaporated spontaneously; strychnine was removed with NH_4OH as above; the filtrate with $AgNO_3$ pptd. the *Ag salt* of *d-α-terpineol acid phthalic acid* (VII). This was washed, dried and decompd. with NaCl soln. and acidified with H_2SO_4 ; VII was pptd., m. 116°, $[\alpha]_D 40.50^\circ$. VII sapond. with KOH-EtOH gave *d-α-terpineol*, $[\alpha]_D 98.50^\circ$. E. J. W.

The isomeric α-terpineols. Active terpineols, from active pinene. VINCENZO PAOLINI. *Gazz. chim. ital.* 55, 812-7 (1925).—In the previous paper (cf. preceding abstr.) the sepn. of the optical isomers of α-terpineol (I) was described. The mechanism of the transformation of pinene into optically active I is reviewed and discussed. By a modification of Flawitzky's method Godlewsky (*J. Russ. Phys.-Chem. Soc.* 31, 203-8, 1899) from *l*-pinene obtained *l-α-terpineol* $[\alpha]_D -95.28^\circ$. P. applied the methods reviewed in the preceding abstr. A fraction, b. 157-8°, $d_{15} 0.80$, $[\alpha]_D -35.5^\circ$, was sepd. from com. turpentine. 150 g. of this pinene with 350 g. 90% EtOH + 150 g. 70% H_2SO_4 were agitated continuously for 10 hrs. The lower layer was then sepd. and poured into ice- H_2O . The lower oily layer was dried well with K_2CO_3 and dissolved in 250 g. PhMe + K in excess. After 48 hrs. this was decanted and treated with $C_6H_4(CO)_2O$ as before and gave a mixt. of ethers, which when sapond. with KOH-EtOH gave terpineol, $[\alpha]_D -57^\circ$. The acid phthalate treated as before with strychnine gave *l-α-terpineol*, $[\alpha]_D -98.32^\circ$, m. 37-8°, $d_{15} 0.935$. The mother liquors from this salt were sapond. and gave I with $[\alpha]_D -27.00^\circ$. The same pinene treated according to Ertschikowsky with glacial AcOH and $ZnCl_2$ gave terphenyl acetate, which on sapon. and treatment as before gave about the same results on sepg. the *l*-form. The results obtained with *l-α-terpineol* here agree with those obtained on sepg. the 2 isomers. E. J. W.

New derivatives of campholcarbinol. H. RUPF AND F. FEHLMANN. *Helvetica Chim. Acta* 9, 80-97 (1926).—Reduction of Et campholate with Na in EtOH gave 55% campholcarbinol (I), purified through the Na campholmethyl phthalate; by-product, *di*[campholmethyl] phthalate, m. 80°. Campholmethyl bromide (II), from I and HBr in AcOH in sealed tubes at 100°, b. 94-5° and is rather unstable; it could not be com-

condensed with $\text{H}_2\text{C}(\text{CO}_2\text{Et})_2$ or $\text{AcCH}_2\text{CO}_2\text{Et}$. Shaken with AgOAc in AcOH , **II** gave a hydrocarbon $\text{C}_{10}\text{H}_{18}$ (**III**), b. 164° . Treated with Mg and the product decomposed with H_2O , **II** gave a mixt. b. $46-8^\circ$, of **III** with a solid hydrocarbon $\text{C}_{10}\text{H}_{20}$, and also a hydrocarbon $\text{C}_{20}\text{H}_{38}$, b. $177-8^\circ$. With PhNH_2 at 150° , **II** gave **III** and campholmethylaniline (**IV**), m. 59° , b. 173° ; HCl salt (from Et_2O), m. 156° (decompn.); nitrosamine. **I** heated with H_3PO_4 also formed **III**, which added HBr to give **II**, identified by conversion to **IV**. Campholmethyl phenylthionocarbamate, from **I** and PhNCS (16 hrs. at 120°), m. 101° . The following esters of **I** were made by warming with the acid chloride and excess $\text{C}_6\text{H}_5\text{N}$: acetate, b. 101° ; propionate, b. 112° ; camphocarboxylate, m. 145° ; phenylacetate, b. 191° ; hydrocinnamate, b. 206° ; cinnamate, b. 217° , b. 148° ; *p*-nitrobenzoate, yellow, m. 95° , yields on reduction the *p*-aminobenzoate, waxy mass, b. $242-3^\circ$, m. 74° ; HCl salt (from Et_2O), m. $140-6^\circ$ (decompn.). Camphol Me ketone (90% yield from campholyl chloride and ZnMe_2) brominated in AcOH , CS_2 or CHCl_3 , gave campholacyl bromide (**V**) (RCOCH_2Br ; cf. "phenacyl"), b. $138-42^\circ$, m. 35° , sensitive to light and air, and campholacyldibromide (**VI**), b. 164° , m. 52° . Campholymethyl acetate, through **V**, b. 146° , gave with MeOH contg. dry HCl , campholylcarbinol (**VII**), b. $123-5^\circ$; benzoate, m. 82° ; phenylacetate, b. 224° , neither **VII** nor its benzoate formed a semicarbazone. Reduction of **VII** with Na - or Al-Hg gave chiefly camphol Me ketone. **VI** heated with KOH in MeOH gave an oil, b. $128-30^\circ$, probably campholglyoxal dimethylacetal, $\text{C}_9\text{H}_{17}\text{COCH}(\text{OMe})_2$, reduces warm Fehling soln.; semicarbazone, m. 181° . Campholacylphthalimide, from **V**, m. $98-9^\circ$; campholacylphthalamidic acid, m. 143° (decompn.); campholacylamine, b. 128° , yields with HNO_2 **VII**, identified as the benzoate; campholacylphenylthiourea, m. 105° (decompn.). **V** and McNH_2 formed campholacylmethylamine, b. 123° ; the distn. residues yielded some *di*[campholacyl]methylamine; HCl salt, m. 199° ; campholacylmethylphenylthiourea, m. 147° ; *di*[campholacyl]aniline, yellow, m. 212° , insol. in acids. Similarly, campholacyltrimethylammonium bromide, m. 230° (decompn.); campholacylpyridinium bromide, m. 214° . Condensation of camphol Me ketone and HCO_2Am with NaOEt in Et_2O yielded 75% of the hydroxymethylene deriv., campholylvinyl alc. (**VIII**), b. $122-3^\circ$, which gives characteristic reactions with Fe and Cu salts, and is reduced by H_2 (Ni catalyst) to campholylethyl alc. (**IX**), b. $146-8^\circ$.

BEN H. NICOLET

Optically active esters of campholylcarbinol and of campholylethyl alcohol. H. RUPP and J. PERRET. *Helvetica Chim. Acta* 9, 97-115 (1926); cf. preceding abstr., to which nos. below **IX** refer. The rotations given are in each case for $\lambda = \text{C, D, E}$ (Hg) and F ; (b) indicates 10% soln. in C_6H_6 : **V** (b), 49.74, 63.77, 76.36, 102.80; **VII**, d_{20} 1.0002, 68.98, 87.16, 103.07, 134.33; acetate of **VII**, d_{20} 1.0256, 50.55, 63.28, 74.34, 95.37; benzoate of **VII** (b), 30.87, 38.33, 44.12, 54.11; propionate of **VII**, b_{11} 157°, d_{20} 1.0155, 49.71, 62.28, 73.16, 93.60; butyrate of **VII**, b_{11} 167.5°, d_{20} 1.0021, 46.48, 58.32, 68.40, 87.34; phenylacetate of **VII**, d_{20} 1.0668, 39.84, 49.90, 58.63, 74.63; hydrocinnamate of **VII**, b_0 136-8°, d_{20} 1.0566, 36.20, 45.27, 52.99, 67.27; camphol glycol (**X**), m. 108° , b. 146° , (b) 38.91, 47.60, 55.45, 70.45; acetate of **I**, d_{20} 0.9433, 36.72, 46.72, 55.04, 71.36; propionate of **I**, d_{20} 0.9341, 36.94, 46.60, 54.91, 71.02; butyrate of **I**, b_{11} 128.5-9°, d_{20} 0.9280, 35.73, 45.04, 53.08, 68.75; phenylacetate of **I**, d_{20} 1.0042, 29.06, 36.62, 43.22, 56.07; hydrocinnamate of **I**, d_{20} 0.9988, 26.80, 33.81, 39.89, 51.69; cinnamate of **I**, d_{20} 1.0167, 32.43, 41.25, 49.06, 64.93; **VIII**, d_{20} 0.9946, 48.03, 59.85, 69.72, 87.56; **IX**, b_{12} 143°, d_{20} 0.9974, 42.76, 52.94, 61.29, 76.03; acetate of **IX**, b_{12} 159°, d_{20} 1.0103, 35.05, 43.35, 51.05, 61.96; propionate of **IX**, b_0 93-4°, d_{20} 1.0006, 34.36, 42.48, 49.18, 61.02; butyrate of **IX**, b_0 104-6°, d_{20} 0.9886, 32.78, 40.64, 47.07, 58.41; campholylethyl bromide, b. $127-35^\circ$, 1.2042, 39.87, 49.77, 57.98, 72.86. Optical anomalies were few and slight. **X** was made in 42% yield by reduction of the acetate of **VII** in dil. alc. with Na-Hg ; it is sol. in alkalis; diacetate of **X**, b. $205-7^\circ$; monobenzoate, b. $198-9^\circ$. HNO_2 oxidizes **X** to **VII**. The prepn. of **VIII** was improved; benzoate of **VIII**, m. 65° ; hydrocinnamate of **VIII**, b. $216-8^\circ$; both esters decomp. on long standing, apparently to form *s*-tri-campholylbenzene, m. 136° , mol. wt. in C_6H_6 519-547, calcd. 534.6, found as a by-product in the prepn. of **VIII**. The Na salt of **VIII** gave with $\text{MeC}_6\text{H}_4\text{NH}_2 \cdot \text{HCl}$ in H_2O , β -campholylvinyl-*p*-toluidine, yellow, m. 80° (decompn.). Campholylethyl phenylthionocarbamate, from **IX** and PhNCS , yellow, m. 154° . Varied attempts to prep. campholylethylene by dehydration of **IX** gave a polymer, white amorphous powder, m. above 250° , mol. wt. in C_6H_6 800-1152.

BEN H. NICOLET

Phytochemical studies. **II**. Amyrin of elemi resin. OTTO DISCHENDORFER. *Monatsh.* 46, 399-408 (1926); cf. *C. A.* 18, 246.—The f.-p. curve of mixts. of α - and β -amyrin shows a eutectic at 181° and 77% of the α -form; in detg. this point, the clearing point of the mixt. is used, since this is fairly sharp, while the m. p. extends over an interval of $5-15^\circ$. α -Amyrin anisate, m. 193° ; Liebermann's cholesterol test gives

a pale red color; the concd. H_2SO_4 soln. is colorless; mol. wt. in camphor, normal; $[\alpha]_D^{20}$ 102.2° (13.347 mg. in 403.57 mg. C_6H_6 , d. 0.8767); 101.5° (25.02 mg. in 727.96 mg. C_6H_6 , d. 0.8805). β -Deriv., m. 250°; Liebermann's test gives a bluish red; $[\alpha]_D^{20}$ 97.36° (32.446 mg. in 517.516 mg. C_6H_6 , d. 0.8863); 98.29° (58.925 mg. in 967.296 mg. C_6H_6 , d. 0.8857); α 1.533, β 1.522, γ 1.671 (calcd.); other crystallographic data are given. These 2 derivs. show no eutectic. α -Amyrin *m*-nitrobenzoate, m. 233°; the Liebermann test gives a pale red color; $[\alpha]_D^{20}$ 97.62° (25.306 mg. in 860.27 mg. C_6H_6 , d. 0.8818), the β -deriv., m. 236°; Liebermann's test gives a bluish red color; $[\alpha]_D^{20}$ 96.74° (20.713 mg. in 853.601 mg. C_6H_6 , d. 0.8802). A mixt. of these 2 derivs. shows very little depression of the f. p. α -Amyrin formate, m. 190°; Liebermann's cholesterol test gives a deep dark violet red color; $[\alpha]_D^{20}$ 80.4° (18.398 mg. in 450.473 mg. C_6H_6 , d. 0.8812); 73.87° (0.8482 g. in 42.294 g. CHCl_3 , d. 1.4734); sapon. gives α -amyrin, indicating that the HCO_2H had caused no rearrangement. β -Deriv., m. 240°; Liebermann's test gives a deep dark bluish violet color; $[\alpha]_D^{20}$ 49.76° (18.569 mg. in 479.114 mg. C_6H_6 , d. 0.8834); 52.36° (0.7381 g. in 38.0778 g. CHCl_3 , d. 1.4713). A mixt. of the formates shows a eutectic at 176° and 71% of the α -form.

C. J. WEST

Some *p*-alkoxybenzohydrylamines. C. TORRÉS Y GONZALÉS. *Bull. soc. chim.* 37, 1591-6(1925).—This article gives methods of prepn. and properties for homologs of the *p*- $\text{ROC}_6\text{H}_4\text{CH}(\text{NH}_2)\text{Ph}$. Certain mono- and dialkoxy *p*-derivs. of Ph_2CHNH_2 having the properties of local anesthetics, have been previously discussed (cf. *J. pharm. chim.* [8] 1, 576). Nearly all of the series, together with the raw materials used in their prepn., are unknown. *Ethoxybenzohydrylamine* (I). For prepn. cf. Gatterman and Eberhardt, *Ber.* 23, 1206; Klages and Allendorff, *Ber.* 31, 1001. $\text{BzC}_6\text{H}_4\text{OEt}$, obtained in 331 g. yield from 280 g. BzCl + 244 g. PhOEt + 400 cc. CS_2 + 270 g. of AlCl_3 , b. 215-25°, b_{25} 245-50°, m. 47-8°. The ketoxime, from the ketone and NH_4OH HCl in 75% yield, m. 135-6°. I, obtained in 24 g. yield from 50 g. of oxime with 2 kg. Na-Hg in AcOH , is a non-distillable oily liquid. Its HCl salt, m. 229°. *Propoxybenzohydrylamine* (II), $\text{BzC}_6\text{H}_4\text{OPr}$, m. 65-6°. The oxime, m. 104-5°. II.HCl (14 g. from 17 g. oxime), m. 220-1°. *Butoxybenzohydrylamine* (III), $\text{BzC}_6\text{H}_4\text{OBu}$, b. 235-45°, m. 38-9°; the oxime m. 94-5°; the III.HCl (13 g. from 17 g. oxime), m. 213-4°. *Isoamloxybenzohydrylamine* (IV). The ketone, b. 225-40°; oxime, m. 93-4°; IV.HCl, m. 224-5°. *Phenoxybenzohydrylamine* (V). The ketone (95% yield), m. 70-4°; oxime, m. 124°; V.HCl, m. 218-9°. *Et benzohydrylamine-p-oxacetate*, $\text{C}_6\text{H}_5\text{CH}(\text{NH}_2)\text{C}_6\text{H}_4\text{OCH}_2\text{CO}_2\text{Et}$ (VI). The ketone is obtained by condensing $\text{PhCOC}_6\text{H}_4\text{OH}$ (cf. Dobner, *Ann.* 210, 224) with $\text{ClCH}_2\text{CO}_2\text{Et}$ in the presence of soda. The VI.HCl, m. 183-4°. The phenylbenzylamines are obtained in a similar manner except that BzCl is replaced by PhCH_2COCl in the prepn. of the ketones. *Diphenylethylamine* $\text{PhCH}_2\text{CH}(\text{NH}_2)\text{Ph}$ (VII). Ketone, m. 57°, b. 320-2°; b_{12} 177°. Oxime, m. 97-8°; VII.HCl, m. 251-2°. *p*-Methoxyphenylbenzylamine, $\text{PhCH}_2\text{CH}(\text{NH}_2)\text{C}_6\text{H}_4\text{OMe}$ (VII). The ketone, m. 77°, and the oxime, m. 114°, are known. VIII.HCl, m. 234-5°. *Ethoxyphenylbenzylamine* (IX). Ketone, m. 105-6°. Oxime, m. 89-90°. IX.HCl, m. 203-4°. Resolution of I into optical isomers is effected by treating 10 g. I.HCl with 1 equiv. of NH_4 bromocamphorsulfonate in 60 cc. abs. alc. and pptg. by 140 g. distd. water, yield 9.98 g., m. 174-5°. The substance is purified by successive recrystns., and the base freed by the calcd. amt. of soda. It is extd. by Et_2O and has $\alpha_D -3.99^\circ$, m. 201-2°. The mother liquors, cooled to 0°, furnish the remainder of this substance and then a new crystn. of *dl*-bromocamphorsulfonate, m. 174°. The mother liquors from these two crystns., treated with soda give a non-cryst. base, α_D 3.37°. HCl salt of *d*-rotatory base, m. 223-4°; of *l*-rotatory base 221-2°; of *dl* base 229-30°.

H. W. GIBSON

Constitution of the so-called diphenylcyclobutane. R. STOKER and CL. THIER (in part with E. LAAGH). *Ber.* 58B, 2607-15(1925); cf. *ibid.* 38, 1965(1905). The supposed 1,3-diphenylcyclobutane obtained, together with $\text{C}_6\text{H}_5\text{Ph}$ and other products, by heating PhCH_2CHO with alc. KOH under pressure has been shown to be really $\text{PhCH}_2\text{CH}:\text{CHPh}$ (I) (Dieckmann and Kammerer, *Ber.* 39, 3048(1906)); it is assumed that the PhCH_2CHO is first converted into the aldol $\text{PhCH}_2\text{CH}(\text{OH})\text{CHPhCHO}$ (II), which, under the influence of the alc. KOH, loses H_2O and the CHO group (as $\text{HC}_2\text{O}_2\text{H}$). Under the altered conditions now used in prepg. the I (heating the PhCH_2CHO with the alc. KOH in open vessels), the mother liquors on acidification no longer yield Na_2CO_3 -sol. but only Na_2CO_3 -insol. products which, however, dissolve, although with difficulty, in hot alkalis. From these were isolated small amts. of 3 compds. $\text{C}_{14}\text{H}_{12}\text{O}_2$, m. 109° (III), 133° (IV) and 165° (V) (apparently lactones), and the dry Na salt of III, heated

with Me_2SO_4 in an attempt to prep. a Me ester, yielded a 4th isomer (VI), m. 135° , which strongly depressed the m. p. of IV. III also exists in a 2nd dimorphous form (VII), m. 122° , and could never be obtained again, as on soln. and seeding it always immediately changed into VII; no further analogous rearrangements could ever be effected. The formation of these compds. may be explained by assuming that the aldol II changes under the influence of the alc. KOH into the unsatd. aldehyde $\text{PhCH}_2\text{CH}:\text{C}(\text{Ph})\text{CHO}$ which adds another mol. of PhCH_2CHO to form the dialdehyde $\text{PhCH}_2\text{CH}(\text{CHPhCHO})\text{CHPhCHO}$; this undergoes a Cannizzaro reaction and the resulting $\text{PhCH}_2\text{CH}(\text{CHPhCH}_2\text{OH})\text{CHPhCO}_2\text{H}$ yields α,γ -diphenyl- β -benzyl- δ -valerolactone, $\text{PhCH}_2\text{CH}(\text{CHPh})\text{CO}_2\text{O}(\text{CH}_2\text{CHPh})$ (VIII). VIII may theoretically exist in 4 isomeric

dl-forms according as the Ph and PhCH_2 groups lie on the same or on different sides of the plane of the lactone ring. I (5.8 g. from 10 g. PhCH_2CHO refluxed 2 hrs. with 5 g. KOH in 35 cc. alc.), b_{14} $178-9^\circ$, m. $15-6^\circ$, mol. wt. in boiling C_6H_6 195.9; dibromide, m. 109° ; pseudonitrosite, m. $142-50^\circ$ (depending on the rate of heating) with effervescence, dissolves in boiling xylene with green color but not without decompn., gives with NH_2Et in hot alc. the nitrodiethylamine, $\text{C}_{18}\text{H}_{24}\text{O}_2\text{N}_2$, yellowish, m. 93° ; nitroschloride, m. 166° (foaming), sol. in C_6H_6 with green color. In boiling alc. with Na or in alc. with H and palladinized CaCO_3 I gives $\text{CH}_2(\text{CH}_2\text{Ph})_2$, b_{16} $166-8^\circ$, b. $301-3^\circ$. With alk. KMnO_4 I gives, together with much unchanged I, only BzH, BzOH and $\text{PhCH}_2\text{CO}_2\text{H}$; with KMnO_4 in Me_2CO and H_2SO_4 is obtained also a compd. (IX), m. $116-7^\circ$, which reduces Fehling soln. and $\text{NH}_3\text{-AgNO}_3$ and forms a semicarbazone, m. 189° and regenerating IX on boiling with 10% H_2SO_4 ; IX has the compn., $\text{C}_{16}\text{H}_{14}\text{O} \cdot \text{H}_2\text{O}$, of an α,β -diphenylpropionaldehyde hydrate, possibly formed by migration of a Ph group in the glycol $\text{PhCH}_2\text{CH}(\text{OH})\text{CH}(\text{OH})\text{Ph}$ resulting from the oxidation of the I. It dissolves in concd. H_2SO_4 with a dark red color destroyed by the addn. of H_2O , forms no oxime and could not be converted into the corresponding acid. Ozonization of I in AcOH gave only BzH, BzOH and $\text{PhCH}_2\text{CO}_2\text{H}$. C. A. R.

1-Phenylnaphthalene and its derivatives. RICHARD WEISS AND KARL WOLDICH. *Monatsh.* **46**, 453-8(1926). -- $1\text{-C}_{10}\text{H}_7\text{Ph}$ (I) (Möhlau and Berger, *Monatsh.* **26**, 1198), b_{17} , 334° , results in 33 g. yield by heating 55 g. 1-phenyldialin (b_{12} $175-7^\circ$; in 28 g. yield from 61.5 g. PhBr, 10 g. Mg and 50 g. 1-tetralone) with S at 250° and in 4 g. yield from 8 g. tetrahydrophenylnaphthalene (b_{760} 332° , m. 36°); in 6 g. yield from 10 g. $\alpha\text{-C}_{10}\text{H}_7\text{Br}$, 1.2 g. Mg and 4.2 g. cyclohexanone) and S-Br deriv., b_{12} $210-20^\circ$, m. 70° ; 7 g. from 10 g. I and 7.5 g. Br. In AcOH, HNO_3 gives from 8 g. I 6 g. of a NO_2 deriv., yellow, m. 132° . The NH_2 deriv. is an oil and was analyzed as the HCl salt, crystg. with 0.5 H_2O and m. 234° (decompn.); *Ac* deriv., m. $169-70^\circ$. *p*-Nitrophenylazo-*p*-aminophenylnaphthalene, green, shimmering needles, m. $220-2^\circ$, from the NH_2 deriv. and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{N}(\text{NO})\text{Na}$. Reduction with SnCl_2 in AcOH-HCl gives *p*-diamino-1-phenylnaphthalene, whose *di-Ac* deriv. m. 278° . *Na* phenylnaphthalenesulfonate, glistening needles. C. J. WEST

A mercuri-organic compound of phenyl- β -naphthylamine. G. ROSSI AND B. CECCHETTI. *Gazz. chim. ital.* **55**, 869-72(1925). -- $\beta\text{-C}_{10}\text{H}_7\text{NHPh}$ in alc. is treated with $\text{Hg}(\text{OAc})_2$ in 50% EtOH slightly acid with AcOH. The soln. is heated on the H₂O-bath about 30 min. and after 12 hrs. a yellow ppt. m. 173° , is filtered off; this is probably mercuriphenylnaphthylamine, $\text{C}_{16}\text{H}_{14}\text{Hg} \cdot \text{C}_{10}\text{H}_6\text{NH} \cdot 2\text{EtOH}$. The presence

of EtOH in this compd. was demonstrated by the CHI_3 test. E. J. WITZEMANN

Acetylene derivatives. V. Phenyl- β -naphthylacetylene. PAUL RUGGLI AND MARC REINERT. *Helvetica Chim. Acta* **9**, 67-79(1926); cf. C. A. **15**, 1369. -- PhCH_2COCl and C_{10}H_8 in CS_2 gave with AlCl_3 , 77% of a mixt. of α - and $\beta\text{-C}_{10}\text{H}_7\text{COCH}_2\text{Ph}$ (I and II), sepd. as the picrates from C_6H_6 ; picrate of II (less sol.), m. $142.5-3.5^\circ$; picrate of I, m. $101-2^\circ$; I, m. $66-7^\circ$; II, m. $99-9.5^\circ$; phenylhydrazones of I, m. $101-1.5^\circ$, decomp. on standing; phenylhydrazone of II, m. $165-7^\circ$; oxime of I, m. $148-52^\circ$ (decompn.); oxime of II, m. $128-9.5^\circ$. Oxidation of I and II with KMnO_4 in dil. $\text{C}_6\text{H}_5\text{N}$ gave chiefly α - and β -naphthylphenylglyoxal, yellow, m. $101.5-2^\circ$ and $86.5-7^\circ$, resp., and giving with $\alpha\text{-C}_6\text{H}_4(\text{NH}_2)_2$ α - and β -naphthylphenylquinoxalines, yellow, m. $137-9^\circ$ and $108-10^\circ$. Heated 0.5 hr. in CHCl_3 with PCl_5 , II evolved HCl and gave 1-phenyl-2- β -naphthyl-2-chloroethylenes, m. $116-7^\circ$, very stable toward hot alc. KOH; boiled 2 hrs. in $\text{C}_6\text{H}_5\text{N}$ with KOH, it gave phenyl β -naphthylacetylene, m. $115-6^\circ$, which, dissolved in concd. H_2SO_4 and let stand some hrs., re-forms II. With PBr_5 in C_6H_6 II yielded 1-phenyl-1-bromo-2- β -naphthyl-2-ketoethane, m. $111-1.5^\circ$, hydrolyzed by KOH in MeOH to 1-phenyl-1-hydroxy-2- β -naphthyl-2-ketoethane, m. $151-2^\circ$. With PCl_5 , I gave 1-phenyl-1,2-dichloro-2- α -naphthylethane, m. 102° (evolution of HCl); on repeated distn. in

vacuum, it formed 1-phenyl-2-chloro-2- α -naphthylethylene, oil, b_{11} 228–33°, loses only 10% of its Cl when boiled 7 hrs. with KOH in C_6H_5N . With PBr_3 I gave, according to the conditions, 1-phenyl-2-bromo-2-[dibromo- α -naphthyl]ethylene, m. 170–1°, or 1-phenyl-1-bromo-2- α -naphthyl-2-ketoethane, m. 63–4°. Hydrolysis of the latter formed 1-phenyl-1-hydroxy-2- α -naphthyl-2-ketoethane, m. 105–5.5°. BEN H. NICOLET

Decahydronaphthalene and its substitution products. I. GYSIN. *Helvetica Chim. Acta* 9, 59–67(1926).—Decalin was sprayed by Cl_2 into a chamber; as catalysts light and 1% I_2 were used (app. described in G.'s, *Diss. Geneva*, 1925). From 270 g. 120 g. chlorodecalin (I) and 60 g. dichlorodecalin (II) were formed. KCN in EtOH or AgCN in AmOH gave with I no cyanodecalin, but some octalin. Attempts to prep. decalindicarboxylic acid from II by the Grignard reaction, and to rearrange decalin carboxamide to the amine, failed. By means of $AlCl_3$, I was condensed with a no. of aromatic substances, yields averaging 50%; the position taken by the $C_{10}H_{17}$ is to be determined later. The following products are described: phenyl, b_{18} 170–80°; tolyl, b_{18} 180–90°; *m*-xylol, b_{18} 182–92°; *cymyl*, b_{18} 192–212°; *anisyl*, b_{18} 185–95°; *m*-dimethoxyphenyl, b_{18} 225–35°; *p*-dimethoxyphenyl, b_{18} 208–25°; naphthyl, b_{18} 240–80°, gave two isomers, m. 62° and 68°. BEN H. NICOLET

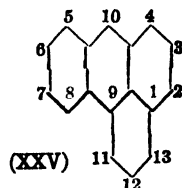

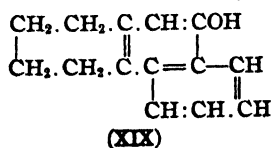

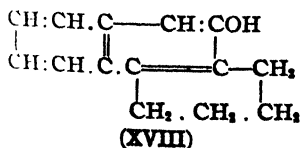

Radical dissociation of arylated succinic acid derivatives. II. Radical dissociation of tetraarylsuccinodinitriles. A. LÖWENBEIN AND R. FÜRST GAGARIN. *Ber.* 58B, 2643–4(1925); cf. *C. A.* 19, 2043.—In view of the appearance of the paper of Blicher (*C. A.* 19, 1858), L. and G. give the exptl. evidence which they have obtained of the dissociation of tetraphenylsuccinodinitrile (I) into free radicals. As I itself begins to dissociate only at about 140° it was sought to lower the temp. limits of the dissociation by the introduction of suitable substituents in the Ph residues. Tetra-*p*-anisylsuccinodinitrile, from $(MeOC_6H_4)_2CHCN$ (II) boiled 0.5 hr. with $K_2Fe(CN)_6$ in 15% NaOH slowly liquefies 220–40°, gradually becoming redder and redder, dissolves in concd. H_2SO_4 with intense blue color; the colorless solns. in $CHCl_3$, EtOH, C_6H_6 or AcOH assume on warming a vivid pink color and a very intense yellow fluorescence which slowly disappear on cooling; the dissociation begins at 60–80°, depending on the solvent. The presence of free *di-p*-anisylcyanomethyl radicals is shown by the fact that on long boiling with $PhNHNH_2$ these solns. take up H with regeneration of the original II. *C. A. R.*

Derivatives of β -methylanthraquinone. VII. Nitro derivatives of 1-hydroxy-3-methylanthraquinone and their reaction products. R. EDER AND O. MANOUKIAN. *Helvetica Chim. Acta* 9, 51–9(1926); cf. *C. A.* 19, 2046.—1-Hydroxy-3-methylanthraquinone (I) and 2 mols. KNO_3 in 4 parts concd. H_2SO_4 , heated 5 hrs. at 100°, gave chiefly the 2,4-dinitro deriv. of I (II), m. 275–6° (decompn.). From the mother liquors the 2-nitro (III), m. 272–3° (decompn.), and 4-nitro deriv. (IV), m. 241–2°, were obtained. Nitration of III or IV gave II, which yielded $C_6H_4(CO)_2O$ on oxidation. II, III and I methyl-2-nitro-4-hydroxyanthraquinone all resisted replacement of the NO_2 by OMe when heated with KOMe (cf. *Ber.* 37, 59(1904)). II, refluxed 15 hrs. with NaOMe, showed much reduction. The crude product, heated 6 hrs. at 190° with AcOH and HCl, finally yielded 15% 3-methylpurpurin, m. 231–2°; *Ba salt*, violet needles. Reduction of II, III and IV with Na_2S gave resp. the 2,4-diamino, violet, m. 259–60°, 2-amino, violet, m. 238° and 4-amino deriv. (V) of I, red-violet, m. 253–4°. V was also made by hydrolysis of 1-bromo-3-methyl-4-aminoanthraquinone with H_2BO_3 in H_2SO_4 . BEN H. NICOLET

Catalytic hydrogenations under pressure in the presence of nickel salts. IX. Anthraquinone, phenanthrenequinone and benzanthrone. JULIUS V. BRAUN AND OTTO BAYER. *Ber.* 58B, 2667–85(1925); cf. *C. A.* 18, 2162; Schroeter, *C. A.* 19, 1271. The guiding thought of this investigation was the observation that in the catalytic hydrogenation of anthracene (I) the 1st point of attack is, in part, at least, the center ring, just as in the other mild reduction processes, followed by the addn. of 2 more H atoms (in 1 of the side rings, naturally) and finally, in a 3rd phase, there is a shifting of the H (or the double bonds), the center ring becoming aromatic. This remarkable intramol. rearrangement has been confirmed by the behavior of dihydroanthranol (II) which yielded, together with di- (III) and tetrahydroanthracene (IV) (formed without doubt from I, which is produced so readily from II), a compd. which could be proved with certainty to be a 2,3-tetramethylene-1-naphthol (V). Whether catalytic hydrogenation of the I complex proceeds primarily exclusively through the *meso*-nucleus or whether it is accompanied by a simultaneous attack on 1 of the side chains cannot be

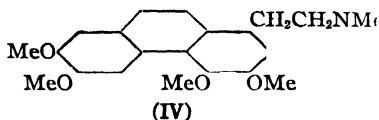

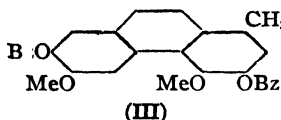

detd. for I itself, but, according to the scheme
$$\begin{array}{c} 4H \\ \text{V} \end{array} \xleftarrow{\text{anthranol (VI)}} \text{II} \xrightarrow{2H} \text{V} + \text{III} + \text{IV}$$
, if only the middle ring is attacked first, the yield of V should, under the same

conditions, not be greater from VI than from II, whereas if there is a simultaneous hydrogenation of a side ring it should be greater. As a matter of fact, II gives only 15% V and almost 80% of III + IV, while with VI these relative yields are reversed. It may be concluded with certainty, therefore, that with VI the addn. of H to a side ring predominates, in fact may be exclusively the primary reaction, and that primary addn. on the *meso*-nucleus occurs only in those mols. in the anthrone form which, under the explt. conditions (at about 200° under high pressures) must certainly be present to a certain extent. It might be objected to the above scheme that V itself may easily be further attacked by H with elimination of the HO group and formation of IV so that the relative yields of V and of III + IV are no true index of the course of the reaction. Such is not the case, however. V can be further hydrogenated, to be sure, but much more difficultly than VI or II and no IV is formed; the aromatic side ring is attacked first and the products are *octahydroanthranol* (VII) and, finally, *octahydroanthracene* (VIII). V and VII, which may be considered as a $C_{10}H_8$ and a C_8H_8 deriv., resp., agree in some of their properties with the known naphthols and phenols but differ in others, probably owing to the loading down of the aromatic rings with cyclic side chains. Both are oxidized to the corresponding quinones (IX and X), are easily brominated in the *p*-position, couple with diazo compds. and can in this way be converted into the *p*-amino phenols (XI and XII) and on alkylation and acylation behave like normal phenols. On the other hand, VII, unlike durenol, is strikingly little sol. in alkalies and XII dissolves in neither alkalies nor acids; V and VII cannot be nitrated, are oxidized by HNO_2 partly to the quinones and partly to the *ditetra*- (XIII) and *dioctahydrodianthranols* (XIV) and form NO derivs. in only small amts. No indications of tautomerism in V and VII have been observed. Unlike hydrogenation with Pt sponge, hydrogenation of anthraquinone with Ni under pressure gives no anthrahydroquinol; the first product which can be isolated is VI, which, under proper conditions, can be obtained practically quant.; further hydrogenation then yields the products described above. The hydrogenation of phenanthrenequinone (XV) proceeds in a manner entirely analogous to that of anthraquinone. There are 3 marked differences in the 2 series, however: (1) With XV it is possible, by moderated reduction, to obtain, along with the 9-phenanthrol (XVI), the *phenanthrenehydroquinol* (XVII), which is therefore certainly the 1st stage in the reduction. (2) Theoretically, 2 *tetrahydrophenanthrols* (XVIII and XIX) are possible, but thus far only 1 form has ever been obtained and it has not been possible to det. whether it is a β - (XVIII) or an α -naphthol (XIX). (3) Probably owing to the greater instability of the hydrogenated derivs. of phenanthrene as compared with those of I, the yields in the former series are not so good and it is more difficult to follow quant. the course of the reactions. Benzanthrone (XX) on catalytic hydrogenation gives a whole series of products different from those hitherto obtained in other ways. No matter how carefully it is hydrogenated, it takes up 4 atoms of H with the formation of *1,9-trimethylene-anthranol* (XXI), which on further reduction apparently follows the left-hand side of the scheme given above, yielding *1,9-trimethylene-5,6,7,8-tetrahydro-anthranol* (XXII) and no trimethylene-anthracene. That in XXI it is the isolated ring which is hydrogenated has not been proved with certainty. Further hydrogenation merely removes the HO group, with formation of *1,9-trimethylene-5,6,7,8-tetrahydro-anthracene* (XXIII); only with Na and alc. can 2 more H atoms be introduced; the product (XXIV), which contains a reactive double bond (adding Br), is assumed, by analogy, to be *1,9-trimethylene-1,4,5,6,7,8-hexahydroanthracene*. It seems impossible to name these new derivs. of XX satisfactorily in accordance with Bally and Scholl's nomenclature (C. A. 5, 3249) and it is suggested that in naming them they be considered as 1,9-trimethylene-anthracene derivs., the positions of the substituents being indicated as shown in the formula XXV. Anthraquinone (XXVI) (100 g.) at 160–70° absorbs 4 atoms H in a few min.: in decalin further hydrogenation occurs readily and,

to obtain VI quant. somewhat less H must be introduced into the autoclave at the end, but in other solvents the reduction often stops at the VI stage so that even this precau-

and yields 1.5 g. *norboldine-HI*, faintly yellowish needles, m. 249–50°, decompd. by boiling H₂O but giving with the calcd. amt. of NaHCO₃ in a CO₂ atm. the free base as a pure white powder which is exceedingly sensitive to O and in alk. soln. at once becomes dark blue in the air. With excess of CH₂N₂ in Et₂O, 10 g. I·CHCl₃ yields 6–7 g. of its *di-Me ether* (II), m. 117–8°, α 108°, insol. in alkalies; *HI salt*, m. 243°. With BzCl in 10% KOH I gives a *tri-Bz deriv.* (III) (the relative positions of the BzO and MeO groups being undetd.), m. 173°, in which the 3rd Bz residue must be on the N; unlike II, it does not react with MeI and is not optically active. Together with III is obtained a small amt. of a *di-Bz deriv.*, m. around 124–7°. *Methiodide* of II, m. 221°, optically active, converted by boiling KOH into the oily optically inactive *methin base* (IV) while with Ag₂O in H₂O is obtained an optically active soln. of the quaternary NH₄ base. *Methiodide* of IV (4.5 g. from 5 g. II·MeI) boiled 10 min. with 20% KOH in MeOH and then treated at 25–30° with an excess of MeI, m. 276–80°; 7 g. of this, shaken with excess of Ag₂O in H₂O, filtered, treated with 10 cc. of 10% KOH and evapd., gives NMe₃ and 3.5 g. 2,3,5,6(?)*-tetramethoxy-8-vinylphenanthrene* (V), m. 143°, which in Me₂CO with aq. KMnO₄ gives 2,3,5,6(?)*-tetramethoxyphenanthrene-8-carboxylic acid*, m. 213–4° and yields on distn. with Zn dust, although in only very small amt., a hydrocarbon having the properties of α-ethylphenanthrene (picrate, m. 134–5°; Pschorr, *Ber.* 39, 3127(1906), gives 138–40°). IV, its methiodide and V with concd. HNO₃ give 1,2,3,4-C₆H₂(CO₂H)₄, m. 237–8°, whose *tetra-Me ester* m. 129°. I with alk. KMnO₄ yields only (CO₂H)₂ and the 2 HO groups are, therefore, probably on different rings. II is probably identical with glaucine (Gadamer, *C. A.* 5, 2641), for which the 2,3,5,6-positions of the MeO groups have been established by synthesis.

C. A. R.

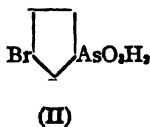

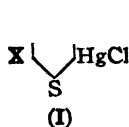

A new dye formed by the action of diethyl oxalate on pyrrolmagnesium bromide. T. N. GODNEV AND N. A. NARYSHKIN. *Ber.* 58B, 2703–5(1925); cf. *Astrachan Mediz. J.* 1922, No. 2–3, 14 pp.—From pyrrolmagnesium bromide (prepd. from 10 g. pyrrole, EtBr and Mg) treated with (CO₂Et)₂ in Et₂O, then decompd. with ice water and NH₄Cl extd. with Et₂O, evapd. and treated with HCl is obtained 4 g. of a dye to which is as-

signed the structure

$$\begin{array}{c} \text{ClH.N:CH.CH:CH.C} \\ \text{NH.CH:CH.CH:C} \end{array} \begin{array}{c} \diagup \\ \diagdown \end{array} \text{C} \quad ; \text{ it is pptd. from CHCl}_3 \text{ at } -10^\circ$$

by ether as an amorphous blue-black powder, insol. or almost insol. in the ordinary solvents except CHCl₃ and C₆H₆N. The free base is obtained by treating the HCl salt with alc. KOH, dilg. with H₂O and extg. with Et₂O. At a concn. of 0.03 g. per l. in a layer 15 mm. thick, the soln. shows complete absorption from λ535 on. C. A. R.

Arsenical derivatives of thiophene. III. C. PINZI. *Gazz. chim. ital.* 55, 824–31 (1925); cf. *C. A.* 10, 1639.—The method of synthesis used for the prepn. of As derivs. of thiophene was used in the prepn. of the halothienylarsonic acids described here. The method consists in the action of AsCl₃ on halogen derivs. of mercurithienyl chloride. 2-Bromo- and 2-iodothiophene treated with HgCl₂ give the corresponding chloro-mercuri derivs. (I) of known constitution (Steinkopf, Bauermeister, *C. A.* 8, 1418). I treated with AsCl₃ and warmed on the H₂O bath gave the corresponding bromo- and iodothienylarsenious chlorides (BrC₄H₂SA₂Cl₂ and IC₄H₂SA₂Cl₂) that could not be

sepd. from the reaction mass but were oxidized in 20% NaOH with 15% H₂O₂ to 5-bromo- (II) and to 5-iodothiophenyl-2-arsenic acid (III), both of which are colorless and infusible. The reaction RAsCl₂ + RHgCl → HgCl₂ + R₂AsCl and the oxidation of

R_2AsCl to R_2AsO_2H takes place to a small extent, giving rise to the bis[halothieryl]-arsinic acids. The prepn. of **II** and **III** was undertaken to aid in establishing the position of the NO_2 group in the nitration product of 2-thienylarsonic acid (C. A. 10, 1641). This NO_2 compd. was reduced with Na-Hg to the corresponding amino acid but attempts to replace this with Br or I after diazotization failed. **III** was easily nitrated with HNO_3 - H_2SO_4 , giving 3(or 4)-nitro-5-iodothieryl-2-arsonic acid, m. 302° , but **II** was recovered unchanged from the nitration mixt. Arsenic compds. contg. a pair of tervalent As atoms united by a double bond $RAs:AsR$ are generally called arseno derivs. and they are prepd. by reduction of primary arylarsonic acids: $RAsO_2H_2 \rightarrow RAsO \rightarrow RAs:AsR$. To the series of reducing agents used for this purpose (H_3PO_3 , $SnCl_2$, Na-Hg, $Na_2S_2O_4$) Bart (C. A. 17, 82) has added H_3PO_2 . This and H_3PO_3 do not act upon the NO_2 group and have enabled F. to obtain 5 new arsenothiophene derivs. To 2 g. thienylarsonic acid in 15 cc. EtOH an excess of cryst. H_3PO_2 was added. The mixt. was heated on the H_2O bath and sepd. 2,2-arsenothiophene, yellow, softens without melting, insol. in common solvents. H_3PO_2 reacts more promptly, giving the same product. 5,5'-Dinitro-2,2'-arsenothiophene (**IV**), greenish yellow, browns at 150° , explodes $170-8^\circ$, detonates violently in the open flame, 5,5'-dibromo-2,2'-arsenothiophene, yellow, softens 130° , m. 170° (decompn.), 5,5'-diiodo-2,2'-arsenothiophene, yellow, softens 135° , m. 175° , and dinitro-5,5'-diiodo-2,2'-arsenothiophene (**V**), yellow, softens 120° , decomps. 140° , were all obtained similarly from the corresponding acids. These arseno derivs. are oxidized back to the corresponding acids with alk. H_2O_2 . The diaminoarseno derivs. corresponding to **IV** and **V**, as well as their pharmacol. action, will be described in another paper. Steinkopf (C. A. 11, 2326) obtained triithienylarsine on fractional distn. *in vacuo* of thiophenearsonic acid derivs. The same compd. is obtained from 2-bromothiophene + $AsCl_3$ in Et_2O when treated with Na thus: $3C_4H_3BrS + AsCl_3 + 6Na \rightarrow 3NaBr + 3NaCl + (C_4H_3S)_3As$.

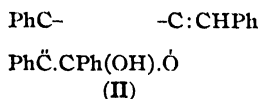

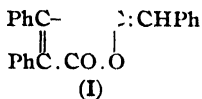

E. J. WITZEMANN

Formation of 2-phenyl-3-arylindones from benzalphthalide, hydrolysis of the latter to a new acid and the preparation of a stereoisomeric benzalphthalide. RICHARD WEISS and ROBERT SAUERMAN. Ber. 58B, 2736 10(1925).—Gabriel's benzalphthalide (**I**), m. 108° , with arylmagnesium bromides gives indones in satisfactory yields. With NH_3 in alc. **I** gives a (non-hydrated) *allo-desoxybenzoic-o-carboxylic acid* (**II**), $C_{15}H_{12}O_3$, isomeric with that obtained by G. and Michael (Ber. 11, 1018(1878)) with boiling alc. KOH; which of the 3 possible forms (keto and 2 *cis-trans* enolic) corresponds to each of the isomers cannot be detd. as yet. Boiling with alc. HCl and pptn. from aq. alk. soln. with concd. HCl converts **II**, with loss of H_2O , into an *allo-benzalphthalide* (**III**), indicating that **II** is an enol. **III** can no longer be hydrolyzed by alkalis and does not react with Grignard reagents. 2,3-Diphenylindone, from **I** in C_6H_6 with $PhMgBr$ in Et_2O , red, m. $153-5^\circ$, sol. in concd. H_2SO_4 with emerald-green color. 2-Phenyl-3-*o*-tolylindone (3.1 g. from 6.5 g. **I** with MeC_6H_4MgBr), orange-yellow, m. $123-5^\circ$, sol. in concd. H_2SO_4 with green color. 3- α -Naphthyl analog (2.2 g. from 4.15 g. **I**), brown, m. $183-5^\circ$, sol. in H_2SO_4 with violet color. **II** (yield, almost quant.), m. 165° , sol. in cold dil. alkalis and not reprecip. by diln. with H_2O . **III** (obtained almost quant.), light yellow, m. $185-7^\circ$, mol. wt. (Rast method) 232.8 6.5; Br deriv., obtained with Br in $CHCl_3$ (0.4 g. from 0.5 g. **III**), m. $211-4^\circ$.

C. A. R.

A synthesis of substituted indones and cyclopentadienones. A. LÖWENBEIN and G. ULLICH. Ber. 58B, 2662-7(1925).—From 10 g. benzaldiphenylmaleide (**I**) in C_6H_6 with $PhMgBr$ in Et_2O is obtained 9 g. of the compd. **II**, m. 210° , insol. in aq. alkalis, sol. in concd. H_2SO_4 with black-violet color, does not react with ketone reagents ($PhNHNH_2$, $NH_2CONHNH_2$), and, although it evolves heat when treated with Grignard reagents, it is recovered unchanged when the reaction mixt. is decompd.; 3 g. boiled a short time with aq. alc. NaOH gives 1.2 g. 2,3,4,5-tetraphenylcyclopenta-2,4-dien-1-one, also obtained in 8 g. yield from 10 g. **II** in hot AcOH treated with HCl gas and in 0.8 g. yield from 1 g. **II** in boiling AcOH with a few drops of concd. H_2SO_4 ; it forms black-violet crystals, m. 218° , whose solns. have a $KMnO_4$ -like color; with $PhCH_2MgCl$ in Et_2O - C_6H_6 it yields 2,3,4,5-tetraphenyl-1-benzylcyclopenta-2,4-dien-1-ol, faintly yellow, m. $155-6^\circ$, 1 g. of which in boiling AcOH with HCl gas yields 0.8 g. 2,3,4,5,6-penta-phenylfulvene, deep red, m. 204° , also obtained in 1.1 g. yield from 1 g. 2,3,4,5-tetraphenylcyclopenta-2,4-diene, BzH and KOMe in boiling MeOH. Benzalphthalide with $PhMgBr$ yields 80% of 2,3-diphenyl-1-indone (**III**), red, m. $150-1^\circ$; in this case no intermediate product analogous to **II** could be isolated but that the **III** is not formed directly by the action of the Grignard reagent is indicated (1) by the fact that even with a large excess of the $PhMgBr$ **III** is the sole product and the yield is even increased, whereas if it were present in the original reaction mixt. it would be expected to react further with the $PhMgBr$ with formation of the colorless triphenylindene; (2) the

reaction mixt. is only faintly yellow and assumes the intensely red indone color only after the hydrolytic decompn. of the soln.

C. A. R.

The action of phenylmagnesium bromide upon the compounds resulting from β -bromoethylphthalimide and γ -bromopropylphthalimide. MORITZ KOHN and ROBERT LAKNER. *Monatsh.* **45**, 617-30 (1925).— $\text{C}_6\text{H}_4(\text{CO})_2\text{NCH}_2\text{CH}_2\text{Br}$ (50.8 g.) and PhMgBr give about 65 g. of 2- β -bromoethyl-3-phenyl-3-hydroxyisoindolin-1-one (I), *m* 189-91°. $\text{C}_6\text{H}_5\text{N}$ gives the salt $\text{C}_{16}\text{H}_{11}\text{O}_2\text{N.C}_6\text{H}_5\text{NBr}$, analyzed as the picrate, $\text{C}_{27}\text{H}_{21}\text{O}_6\text{N}_3$, and chloroaurate, $\text{C}_{21}\text{H}_{19}\text{O}_2\text{N}_2\text{Cl}_4\text{Au}$. $\text{C}_6\text{H}_4(\text{CO})_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}$ and PhMgBr give the 2- γ -bromopropyl deriv. (II), *m* 169-71°; this yields a $\text{C}_6\text{H}_5\text{N}$ salt, analyzed as the chloroaurate. Heated with 20% KOH for 4 hrs, I gives *o*-BzC₆H₄CO₂H; II, after 2 hrs., gives the compd. $\text{C}_{17}\text{H}_{15}\text{O}_2\text{N}$ (III), *m* 126-8°. EtONa and I, boiled 1 hr., give quant. a compd., $\text{C}_{16}\text{H}_{13}\text{O}_2\text{N}$ (IV), *m* 148°; full crystallographic data are given. EtONa and II give the same compd. as obtained by KOH, for which crystallographic data are given. IV and PhMgBr give the compd. $\text{C}_{24}\text{H}_{23}\text{ON}$, *m* 172°, III gives the compd. $\text{C}_{20}\text{H}_{20}\text{ON}$, *m* 194°.

C. J. WEST

The preparation of mercaptobenzothiazole. ERNESTO AZZALIN. *Gazz. chim. ital.* **55**, 895-9 (1925).—Bruni and Romani (*Giorn. chim. ind. e appl.* (1921); cf. *C. A.* **16**, 4093) and Bedford and Scbrell (*C. A.* **16**, 855) found that the vulcanizing action of thiourea and guanidine derivs. is due to the formation of mercaptobenzothiazole (I). P. and R. then found that in the presence of S the Zn salt of I is oxidized, giving the corresponding disulfide and that this is the true vulcanizing agent. A. has studied the formation of I from compds. from which it might be derived most conveniently. NH_4 phenyldithiocarbamate (II) (Freund, Bachrach, *Ann.* **285**, 199) in a sealed tube with 30% of its wt. of S was heated at 250° for 3 hrs. The yellow tar was nearly all sol. in boiling 10% Na_2CO_3 . This when acidified with HCl pptd. impure I, which was purified from Me_2CO . The yield of I was greater when only $\frac{2}{3}$ as much S was used. A mixt. of II with S + PhNH_2 boiled under a condenser 20 hrs. gave anilinobenzothiazole (III), *m* 150-7°. A red soln. of S in $(\text{NH}_4)_2\text{S}$ boiled 20 hrs. with II gave PhNHCSNH_2 , *m* 152°. This same mixt. at 200° for 3 hrs. in a sealed tube gave much S and a little I. S in C_6H_6 boiled 16 hrs. with II gave $\text{CS}(\text{NHPh})_2$ (IV), *m* 149-50°. These results show that the formation of I depends on detd. conditions of temp. and pressure. A mixt. of 5 g. PhNH_2 and 1.73 g. S in 4.1 g. CS_2 heated 3 hrs. at 260° in the sealed tube gives H_2S , a fragile mass of I and a little S + III (an 80% yield of I is obtained). It is thought that IV is formed first and that this decomp., giving PhNH_2 + PhNCS . The latter reacts with S, giving I.

E. J. WITZEMAN

Action of *p*-toluenesulfonazide on malonic ester and alkylated malonic esters. THEODOR CURTIUS and WILFRID KLAVERN. *J. prakt. Chem.* **112**, 65-87 (1926); cf. C. and Ehrhart, *C. A.* **17**, 3876.—*p*- $\text{MeC}_6\text{H}_4\text{SO}_2\text{N}_3$, *m* 22°, and $\text{CH}_2(\text{CO}_2\text{Me})_2$, heated 6 hrs. at 100° and 20 mm. (at ordinary pressures N is split off at 117°, at 14 mm. at 195°) give 85% of 1-toluenesulfon-4-carbomethoxy-5-oxytriazole (I), heavy, yellow oil, which cannot be isolated but changes into the deep yellow 1-toluenesulfon-4-carbomethoxy-5-triazolone (or *Me toluenesulfaminodiazomalonate*) (II), *m* 83°; it may be recrystd. unchanged from hot concd. HCl. II is sol. in EtONa with the formation of the Na salt of I, yellow, decomp. 156° with slight explosion; addn. of acid ppts. the oily I, completely changed into II after 2 hrs. I reddens litmus and is sol. in dil. alkali. I gives a light yellow Ba salt, amorphous; a yellow NH_4 salt, decomp. 154°; a red Fe salt, a green Ni salt, a red Co salt, unstable Ag and bluish green Cu salt, etc.; the yellow piperidine salt, *m* 146° (decompn.). *p*- $\text{MeC}_6\text{H}_4\text{SO}_2\text{N}_3$ and $\text{CH}_2(\text{CO}_2\text{Et})_2$ are condensed by EtONa to 1-toluenesulfon-4-carbethoxy-5-hydroxytriazole, yellow oil, which soon changes to 1-toluenesulfon-4-carbethoxy-5-triazolone, *m* 85° (90% yield); of the enol form there were prepd. the deep yellow Na salt, the amorphous Ph salt, the yellow NH_4 salt, *m* 154° (decompn.) and the piperidine salt, *m* 152° (decompn.). Sapon. with 1:10 NaOH on the H_2O bath gives 80% of 1-toluenesulfon-5-hydroxytriazole-4-carboxylic acid, deep yellow oil, quickly changing to the cryst. *p*-toluenesulfaminodiazomalic acid (III), yellow, *m* 124° (decomp. slowly and after several days, *m* 144°); the Na and NH_4 salts are deep yellow and somewhat unstable as are the metallic salts; the deep yellow Ba salt was analyzed. Hydrolysis of III by heating with 10 parts H_2O on the H_2O bath gives 94% of *p*-toluenesulfaminoglycolic acid, *m* 153°. Heating III in PhMe gives a

yellow compd. m. 192° (decompn.), which may be $C_{10}H_{10}O_4N_2S$ or $C_{10}H_{10}O_4N_2S_2$; the yellow NH_4 salt is hygroscopic; heating in a sealed tube with 20% HCl at 160–70° gives p -MeC₆H₄SO₃H, a compd. m. 230°, with 15.5% N and an oil which was not investigated. With NH_4OH the above esters give 1-toluenesulfon-4-carboxamide-5-hydroxytriazole, yellow oil, changed by heating with EtOH to 4-toluenesulfaminocarboxylic acid-5-hydroxytriazole, anisotropic prisms, decompds. 140° (84% yield). $N_2H_4 \cdot H_2O$ gives 54% of a bis-di- NH_4 salt, m. 212.5°, of 1-amino-4-toluenesulfaminocarboxylic acid-5-hydroxytriazole, slightly anisotropic prisms, m. 164° (decompn.); benzal compd., m. 212° (decompn.); m -nitrobenzal compd., yellow, m. 210° (decompn.); o -hydroxybenzal compd., pale yellow, m. 190° (decompn.). No reaction was observed between p -MeC₆H₄SO₂N₃ and alkylated $CH_2(CO_2R)_2$.

C. J. WEST

Action of benzylsulfonazide on malonic ester. THEODOR CURTIUS and BRUNO JEREMIAS. *J. prakt. Chem.* 112, 88–116 (1926).— $PhCH_2SO_2N_3$ (I) and $CH_2(OEt)_2$ do not react at 110° and 20 mm. When 1 mol. of each is shaken with 2 N NaOH there results 74% of 1-benzylsulfon-4-carbethoxy-5-hydroxytriazole (II), oily, quickly changing into the light yellow *Et* benzylsulfaminodiazomalonalate (III), m. 123°. If the condensation is carried out on the H_2O bath, there results 39% of the *Na* salt, m. 193°, of *Et* benzylsulfonfylmalonalate (IV), anisotropic needles, m. 83°. If the condensation is carried out with EtONa, there results 47% III and 10.5% IV. The *Na* salt of II, pale yellow, m. 184° (decompn.); the NH_4 salt, pale yellow, m. 140° (decompn.); *Ba* salt; Ca, Mn, Zn and Co salts do not give ppts. with the *Na* salt; $FeCl_3$ gives a yellow ppt., $CuSO_4$ a white ppt., while $AgNO_3$, even in the cold, leads to decompn. NaOH (10%) sapon. I to the free acid, smeary mass, which rearranges in a few min. to benzylsulfaminodiazomalonic acid, which is very unstable and is decompd. by H_2O at 70°, giving 68% of benzylsulfaminoglycolic acid, m. 120°; concd. HCl gives $PhCH_2SO_2NH_2$ and $HOCH_2CO_2H$. III and NH_4OH in a sealed tube at 75° for several hrs. give 88.5% of the amide, yellow, m. 148° (decompn.); NH_4 salt, S-yellow, m. 155° (decompn.). $N_2H_4 \cdot H_2O$ gives 63% of the bis-di- NH_4 salt, decomp. 179°, of 1-amino-4-benzylsulfaminocarboxylic acid-5-hydroxy-1,2,3 triazole, anisotropic prisms, decomp. 155°; benzal deriv., pale yellow, decomp. 190°; acetonyl deriv., pale yellow, decomp. 178°; o -hydroxybenzal deriv., yellow, decomp. 187°. IV and $N_2H_4 \cdot H_2O$ in EtOH give 78% of benzylsulfonacetylhydrazide (V), m. 148° and 5.5% of the di- NH_4 salt, m. 232° (decompn.) of the cyclic *sec*-benzylsulfonfylmalonylhydrazide, m. 253° (decompn.). The benzal deriv. of V, m. 179°. V in very dil. HCl, treated with $NaNO_2$, gives benzylsulfonacetyl azide, decomp. 81°; with $PhNH_2$ it gives the anilide, m. 170°, and the *p*-toluidide, m. 151°.

C. J. WEST

Hydrazide and azide of acetylsulfanilic acid and of sulfanilic acid. THEODOR CURTIUS and WILHELM STOLL. *J. prakt. Chem.* 112, 1117–37 (1926).— $AcNHC_6H_4SO_2Cl$ and $N_2H_4 \cdot H_2O$ give acetylsulfanilic hydrazide (I), m. 177–8° (decompn.); *HCl* salt, m. 163–5° (decompn.); dissociated by H_2O ; *Na* salt, decomp. on heating; $AgNO_3$ forms a complex 2 $AgNO_3$, amorphous powder from aq. solns., quickly darkening in the light, leaflets from abs. EtOH, slowly changing in the light. Benzal deriv., m. 182°; acetonyl deriv., m. 174°. I and HNO_2 or $AcNHC_6H_4SO_2Cl$ and NaN_3 give acetylsulfanilic azide (II), m. 107°; it is unchanged by short boiling with concd. HCl. II and $CH_2(CO_2Et)_2$ are condensed by EtONa to the *Na* salt, felt-like needles which decomp. without melting, of acetylsulfanilic-4-carbethoxy-5-hydroxytriazole, yellow oil, changing in a few min. to *Et* acetylsulfanilic acid aminodiazomalonalate, $AcNHC_6H_4SO_2$ -

$NHCO \begin{array}{c} \diagup N \\ || \\ \diagdown N \end{array} \cdot CO_2Et$, pale yellow, m. 146°. Heating I with a little concd. HCl for 5

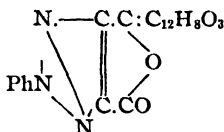

min. gives 75% of sulfanilic hydrazide, $H_2NC_6H_4SO_2NHNH_2$, m. 131°, which reduces Fehling soln. and $NH_4OH \cdot AgNO_3$; di-*HCl* salt, leaflets; benzal deriv., m. 172°; acetonyl deriv., m. 136°. With HNO_2 there results a diazo soln., from which $PhNMe_2$ ppts. the ruby-red *p*-aminobenzenesulfazid-azo-dimethylaniline (III), m. 158° and showing strong pleochroism (violet red-yellow); easily sol. in warm HCl with a bluish red color. II and concd. HCl give sulfanilic azide, pale yellow, m. 36°; the *HCl* salt forms yellow, monoclinic prisms, easily dissociated by H_2O . HNO_2 gives diazoaminobenzenesulfazide, yellow needles which decomp. on heating. The diazo soln. with $PhNMe_2$ gives III; with β -C₁₀H₇OH, *p*-benzenesulfazide-azo- β -naphthol, reddish yellow, m. 161°. $CH_2(CO_2Et)_2$ gives *Et* sulfanilic-aminodiazomalonalate, dirty yellow leaflets; *Na* salt of the enolic form.

C. J. WEST

Triazolic- σ -dicarboxylic acids analogous to phthalic acid. A. BERETTA. *Gazz. chim. ital.* 55, 788–92 (1925).—It is known that the σ -condensed bicyclic and tricyclic systems contg. a pentatomic nucleus show analogy with homogeneous binuclear and trinuclear derivs. Only a brief paper by Pechmann (*Ann.* 262, 308 (1891)) exists on the

analogies of 1,2,3-triazole-4,5-dicarboxylic acid derivs. with those of phthalic acid, 20 g 5-amino-2-phenyl-1,3-benzotriazole (or the equiv. amt. of 6-methyl-5-amino-2-phenyl-1,3-benzotriazole), obtained by oxidizing phenylazo-*m*-phenylenediamine (or phenylazo-*m*-tolylenediamine) with $\text{NH}_4\text{OH} \cdot \text{CuSO}_4$ (Schmidt and Hagenböcker, *C. A.* 16, 1092), were suspended in 50 g. KMnO_4 + 12.5 g. NaOH in 2250 cc. H_2O and heated on the H_2O bath. Gradually the insol. compd. dissolved and NH_3 was evolved. The soln. was decolorized with EtOH and the MnO_2 filtered off. The filtrate was concd. to 200 cc. and acidified with concd. HCl . A mixt. of 2-phenyl-1,2,3-triazole-4,5-dicarboxylic acid (I) and its Na salt were sepd. This was recrystd. from boiling HCl and gave pure I, m. 255° (decompn.). The anhydride (II) formed at the m. p. of I, m. 174° , and resembles $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$. II condensed with resorcinol with ZnCl_2 gave the corre-

sponding triazolefluorescein (III). III with 4 atoms of Br gave

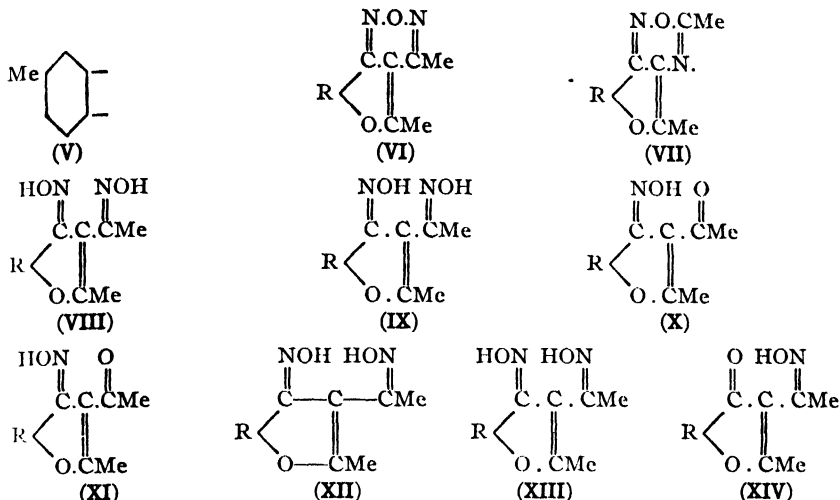

the corresponding triazolic-eosin. II condensed with *m*- $\text{Et}_2\text{NC}_6\text{H}_4\text{OH}$ gave the corresponding rhodamine resembling ordinary rhodamine. A new method of prep. 1-phenyl-1,2,3-triazole-4,5-dicarboxylic acid by oxidation of 5-amino-1-phenylazimino benzene (IV) with alk. KMnO_4 is described. A modification of Zincke's method (*Ann* 313, 262(1900)) of prep. IV is described.

E. J. WITZEMANN

Stereoisomerism of the oximes of 1,3-diketones. I. Action of hydroxylamine on 2,6-dimethyl-3-acetochromone. GEORG WITTIG AND FRITZ BANGERT. *Ber.* 58B, 2627-36(1925).—In detg. the configuration of the oximes described in this paper, W and B. provisionally adopt the conclusions drawn by Meisenheimer from his work on the O_2 cleavage of triphenylisoxazole (*C. A.* 16, 2105). 2,6-Dimethyl-3-acetochromone (I) with NH_2OH in AcOH gives a mixt. sepd. by C_6H_6 into a *mono-oxime* (II) and a *dioxime* (III). Oximation of II in cold NaOH yields a different *dioxime* (IV) which on distn. *in vacuo* forms the *anhydride* VI ($\text{R} = \text{V}$) and with concd. H_2SO_4 , PCl_5 or AcCl undergoes the Beckmann rearrangement in the oximated side-chain, yielding the *oxdiazine* VII; this cannot be oximated and has no basic properties and its formation shows that the oxime group in the side chain of IV must have the configuration represented in formulas VIII or IX, while the formation of VI establishes the γ -configuration (IX) for IV. Concd. HCl converts IV back into II which, since it does not undergo the Beckmann rearrangement with the above reagents, must have the oxime group on the nucleus, a view supported by the impossibility of rupturing the pyrone ring with alkalis or of hydrolyzing off the oxime group even with concd. acids under pressure. Assuming that the conversion of II into IV by alkalis is not accompanied by a stereoisomeric rearrangement which occurs in the reverse direction when the IV is hydrolyzed back to II by acids, II must have the structure X, the configuration of the oxime group being the same as that of the corresponding group in IV; this γ -configuration is further supported by the fact that II is not rearranged by cold NaOH , and only after long boiling with alkalis changes into the α -form (XI), which cannot be converted back into II even by hot concd. acids (under pressure, carbonization occurs), and on further oximation gives III. Oximation of I in AcOH , therefore, gives II and XI, the XI then being further oximated to III. As III is hydrolyzed back to XI by acids and forms no anhydride it must have the α -configuration VIII, which is in harmony with its stability towards alkalis (even fusion with alkalis does not rearrange it). Concd. H_2SO_4 produces no rearrangement in the side chain but splits off the oxime group with formation of XI. With NH_2OH in boiling Na_2CO_3 II gives, together with about 30% of IV, a new *dioxime* which since it is hydrolyzed by acids to II, must have the β -configuration (XII); on vacuum distn. it yields chiefly VI but also some IV, indicating that the XII rearranges into IV which then loses H_2O to form VI; the same rearrangement can be effected by digestion with concd. H_2SO_4 , the product being VII (together with IV if the reaction is interrupted). Long boiling of IV with alkalis gives, together with VI, a 4th δ -*dioxime* (XIII), hydrolysis of which with acids yields a δ -*mono-oxime* (XIV); this with NH_2OH under mild conditions regenerates XIII. II, obtained in 1.1 g. yield, together with 0.8 g. of III, from 2.2 g. I, $\text{NH}_2\text{OH} \cdot \text{HCl}$ and NaOAc in boiling 50% AcOH , yellow, m. $100-0.5^\circ$, sol. in NaOH with yellow color, gives a red-violet color with FeCl_3 . XI (1 g. from 1.4 g. II refluxed 6 hrs. in 2 N Na_2CO_3), m. $157-7.5^\circ$, sol. in Na_2CO_3 , gives no color with FeCl_3 , also obtained in 3 g. yield from 4 g. III in concd. H_2SO_4 on the H_2O bath. XIV (0.1 g. from 0.2 g. XIII with concd. HCl in a sealed tube at 100°), m. $125.5-6.0^\circ$; at the same

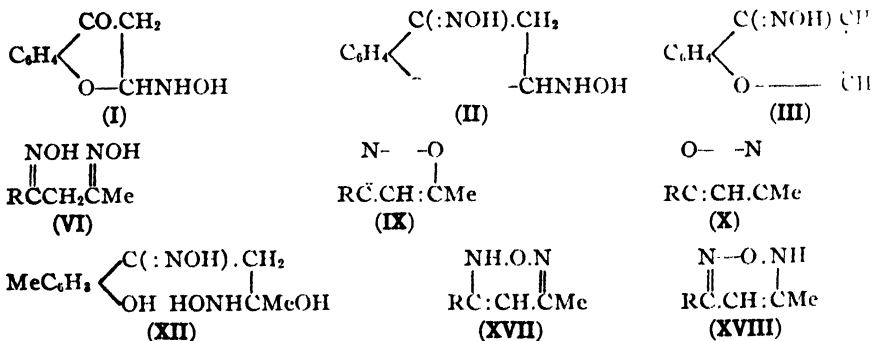

time is obtained 0.03 g. of intensely yellow needles m. 186–7° (whether this is the missing β -mono-oxime has not been detd.). IV (5.1 g. from 5 g. II and $\text{NH}_2\text{OH} \cdot \text{HCl}$ in 2 N

NaOH , m. 159–9.5° on rapid heating, sinters at this temp. on slow heating and finally m. 165–7°, sol. in hot Na_2CO_3 , gives an olive-green color with FeCl_3 , is unchanged by standing 24 hrs. in NaOEt soln., boiling with Na_2CO_3 , heating with H_2O in a sealed tube at 100° or dissolving in concd. H_2SO_4 and reprecip. with H_2O ; 6 hrs. boiling with 50% HCl hydrolyzes it to II and with boiling AcCl it gives the diacetate, m. 131–2° (VII is obtained from the mother liquors on diln. with NaOH), which on soln. in concd. H_2SO_4 and reprecip. regenerates IV and with boiling NaOH gives IV and VI. XII (14.1 g., together with 5.9 g. IV, from 19 g. II refluxed 6 hrs. with $\text{NH}_2\text{OH} \cdot \text{HCl}$ in aq. alc. Na_2CO_3), m. 156–6.5°, depresses the m. p. of IV to 135°, easily sol. in cold Na_2CO_3 , gives no color, when freshly prepd., with FeCl_3 ; diacetate, m. 107–8°. III (1 g. from 1 g. XI with $\text{NH}_2\text{OH} \cdot \text{HCl}$ and NaOAc in boiling AcOH), m. 222–4° (decompn.), mol. wt. in boiling EtOH 217, gives no color with FeCl_3 ; with concd. H_2SO_4 in the ice chest it gives a compd. $\text{C}_{12}\text{H}_{14}\text{O}_3\text{N}_2$, m. 184–4.5°, sol. in NaOH , not attacked by boiling NaOH , resinsified by heating concd. HCl but converted by dil. acid into XI. XIII (3.5 g., together with 8 g. VI, from 30 g. IV refluxed 7 hrs. in 2 N NaOH), m. 194.5–5.0°, gives a dirty green color with FeCl_3 , also obtained from XIV with NH_2OH in very dil. NaOH ; the mother liquors from the XIII yield 4 g. of a compd. $\text{C}_{12}\text{H}_{14}\text{O}_3\text{N}_2$, m. 121–2°, gives an olive color with FeCl_3 , is unchanged by heating 4 hrs. with concd. HCl under pressure at 100°. 3,4-[2',6'-Dimethylchromo]-5-methyl-2,6-oxdiazine-(4) (VI), from IV or XII refluxed in 2 N NaOH or distd. *in vacuo*, m. 88–8.5°, insol. in dil. alkalis and acids, unchanged by concd. H_2SO_4 on the H_2O bath or by concd. HCl at 210°. The isomeric 6-methyl-2,5-oxdiazine-(1) (VII), from IV or XII with concd. H_2SO_4 on the H_2O bath or with PCl_5 in boiling Et_2O , m. 144–4.5°, insol. in dil. acids and alkalis, indifferent towards NH_2OH , boiling alkalis and concd. HCl under pressure at 100°. C. A. R.

Action of hydroxylamine on chromones. GEORG WITTIG AND FRITZ BANGERT. *Ber.* 58B, 2630–42 (1925).—Although the C : O group of chromones reacts with extraordinary sluggishness with ketone reagents it shows a striking reactivity with NH_2OH . From the observations of Harries on analogous compds. (*Ann.* 330, 190 (1904)) it might be expected that NH_2OH first adds at the double bond of the pyrone ring, with formation of a hydroxyaminochromanone (I) whose C : O group can now be oximated with ease, acidification of the product (II) splitting off NH_2OH and yielding the chromone oxime (III). As a matter of fact, NH_2OH in neutral soln. with 2,8-dimethylchromone (IV) and 2,8-dimethyl-4-thiochromone gives the oxime (V) of IV. On the other hand, if IV is oximated in alk. soln. and the still warm reaction mixt. is acidified with a dil. mineral acid, V is again obtained but if AcOH is cautiously added instead of the mineral acid there seps. a compd. $\text{C}_{11}\text{H}_{14}\text{O}_3\text{N}_2$ (VI, R = 3,2-Me(HO)C₆H₃) which is also obtained from 6,2-Me(AcCH₂CO)C₆H₃OH (VII) with NH_2OH , showing that in the oxidation of IV the pyrone ring is ruptured, with formation of the dioxime VI from which hot

mineral acids hydrolyze the oxime group furthest from the C_6H_5 ring with formation of V. With cold acids VI gives, together with V, an alkali-sol. isomer (VIII). V and VIII cannot be converted into each other by concd. alkalis or acids, and VIII, which, unlike V, gives a cornflower-blue color with $FeCl_3$, can also be obtained from VI by the action of alc. NH_3 , *i. e.*, conditions under which chromone formation is impossible VIII can therefore be only the hydroxyphenylisoxazole IX or X. It can also be obtained by heating VI at 160° . Since VI in general shows a tendency to split off the oxime group furthest from the C_6H_5 ring, IX is probably the correct formula for VIII. Alk. oximation of 2,6-dimethylchromone (XI) yields an extremely unstable compd., apparently a hydroxyamino oxime (XII) in which the $NHOH$ group is situated away from the C_6H_5 ring, as with cold acids it readily yields the oxime (XIII) of XI, also obtained with hot mineral acids without the formation of the hydroxyphenylisoxazole (XIV) (X, R = 5,2-Me(HO) C_6H_3), which can be obtained, together with XIII, by fusing the dioxime (XV) of 4,2-Me($AcCH_2CO$) C_6H_3OH (XVI). With alc. NH_3 , XV unexpectedly gave XII, apparently, in the abs. alc. NH_3 added on the oxime group furthest from the C_6H_5 ring, and on acidification was replaced by H_2O ; an analogous NH_3 addn. compd. is probably an intermediate product in the formation of VIII from VI. On long heating with $NaOH$, XV gives an alkali-sol. compd. $C_{11}H_{12}O_2N_2$ which by the Schotten-Baumann method yields a dibenzoate; apparently XV first forms the anhydride (cf. 2,6-dimethyl-3-acetylchromone dioxime, preceding abstr.) in which, under the further action of the alkali, there occurs a shifting of the double bond with formation of the isoxdiazine XVII or XVIII (R = 5,2-Me(HO) C_6H_3); at the same time is formed an isomeric isoxdiazine which with Ac_2O and $NaOAc$ gives a diacetate and which doubtless also has 1 of the structures XVII or XVIII; the soly. in Na_2CO_3 of the 1st isomer and the slight soly. of the latter in $NaOH$ indicate that they are XVIII and XVII, resp. 2-Acetylaceto-6-methylphenol dioxime (VI), obtained in 5.5 g. yield from 5 g. VII or in 75% yield from IV, m. $148-9^\circ$ (slight decompn.), unchanged by heating with H_2O under pressure. V, obtained almost quant. from VI in boiling aq. alc. HCl , in 35% yield from the thiochromone with NH_3OH in aq. alc. and in about 75% yield from IV, m. $145.5-6.0^\circ$. α -[2-Hydroxy-3-methylphenyl]- γ -methylisoxazole (VIII), obtained in 80% yield from VI at $150-60^\circ$, in 30% yield from VI and alc. NH_3 , and in 0.3 g. yield, together with 0.4 g. V, from 1 g. VI in $MeOH$ with cold 0.5 N HCl , m. $90.5-1.0^\circ$. 2-[α -Hydroximinino- γ -hydroximinino- γ -hydroxyacetylaceto]-4-methylphenol (XII), m. $70-3^\circ$, loses H_2O and solidifies and then has the m. p., $122-2.5^\circ$, of 2-acetylaceto-4-methylphenol dioxime (XV); both XII and XV give a blue color with alc. $FeCl_3$. XIII, m. 184.5° . α -[2-Hydroxy-5-methylphenyl]- γ -methylisoxazole (XIV) (yield, 60%), m. $53-4^\circ$. 5-[2'-Hydroxy-5'-methylphenyl]-3-methyl-1,2,6-isoxdiazine (XVIII) (3 g. from 4 g. XV refluxed 6-7 hrs. in excess of 2 N $NaOH$), m. $168-9^\circ$ (slight decompn.), gives an olive-green color with $FeCl_3$; dibenzoate m. $123.5-4.0^\circ$. 3,5-Isomer (XVII) (yield, 0.4 g.), m. $185-7^\circ$ (slight decompn.), gives no color with $FeCl_3$, sol. in hot acids and alkalis and seps. unchanged on cooling, diacetate, m. $155.5-6.0^\circ$.

C. A. R.

Acylation of α -hydroxypyridine. A. E. CHICHIBABIN AND P. G. SZOKOV. *Ber. 58B*, 2650-2(1925).—Meyer believes (*Monatsh.* 26, 1303(1905)) that acylated derivs. of α - and β -pyridones are exceedingly unstable and some, especially the acetates, are not capable of existence at all, but C. and Oparina showed (*C. A.* 19, 3489) that benzoylation of α -pyridone (I) under the most varied conditions always gives the Bz deriv. m. 42° , whose basic properties show that it has beyond doubt the structure

$\text{CH:CH.CH:CH.C(OBz):N}$, and C. and S. have now prepd. the analogous *O-p-nitro-*

benzoate (II) and even the *O-acetate* (III); the latter is characterized by the extraordinary ease with which it is saponified, thus completely excluding the pyridone structure for it. II, from I in a little H_2O treated with 2 parts $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ and then with concd. NaOH to permanent alk., m. $115-6^\circ$, is also obtained by fusing the chloride with 1 equiv. of the Na salt of I, which seps. from alc. in leaflets with $2\text{H}_2\text{O}$. The anhyd. Na salt (in a flask provided with a condenser and connected with an air pump) cautiously treated with the calcd. amt. of AcCl and then heated on the H_2O bath gives III, b_{10} $110-2^\circ$, d_4^{25} 1.1475, stable in the absence of moisture but in the presence of traces of moisture, especially in the light, it becomes blue, then green, and, on distn. after long standing, yields a low boiling fraction smelling of AcOH and a larger residue of higher b. p.; in H_2O it hydrolyzes rapidly, PtCl_4 pptg. the chloroplatinate of I from both the alc. and the aq. solns. The alc. solns. smell of AcOH and even when freshly prepd. give the picrate of I with picric acid.

C. A. R.

Quinoline derivatives. II. Synthesis of $[\beta\text{-}(2\text{-phenyl-4-quinolyl})\text{ethyl}]\text{amine}$ and of $[\beta\text{-}(2\text{-phenyl-6-methoxy-4-quinolyl})\text{ethyl}]\text{amine}$. HANNS JOHN. *Ber.* 58B, 2799-805 (1925); cf. *C. A.* 20, 204, 418.— $\beta\text{-}(2\text{-Phenyl-4-quinolyl})\text{-}\alpha\text{-trichloromethylethanol}$ (I) (24-5 g.) from 15 g. 2-phenyl-4-methylquinoline and chloral refluxed 6 hrs. at $118-20^\circ$, m. 195° ; 6-MeO deriv. (II) (25 g., from 16 g. 2,4,6- $\text{C}_6\text{H}_3\text{NPhMeOMe}$), faintly green, m. 222° ; $\beta\text{-}[2\text{-Phenyl-4-quinolyl}]\text{acrylic acid}$ (III) (6 g. from 10 g. I added in the course of 30 min. to 40 cc. of cold 20% KOH in abs. alc. and heated 1 hr. on the H_2O bath), m. 201° ; *HCl* salt, m. 210° ; sulfate, HgCl_2 gives with the HCl soln. a cryst. ppt., K_2CrO_4 yellow crystals, $\text{K}_4\text{Fe}(\text{CN})_6$ a voluminous blue-green ppt., I-KI with the H_2SO_4 soln. a red-brown, indistinctly cryst. ppt.; picrate, golden yellow; Me ester, m. 123° . 6-MeO deriv. (IV) of III (6.6 g. from 10 g. II), m. 239° , intensely yellow; *HCl* salt, yellow; sulfate; picrate, golden yellow; Me ester, m. 140° . $\beta\text{-}[2\text{-Phenyl-4-quinolyl}]\text{propionic acid}$ (V) (9.4-9.6 g. from 10 g. III in AcOH gently boiled 12 hrs. with colorless HI (d. 2.0) and red P), m. 215° ; *HCl* salt, m. 189° ; III salt, faintly yellow, m. 208° ; sulfate; picrate, yellow; Me ester, m. 63° . 6-HO deriv. (VI) of V (8.5 g. from 10 g. IV), m. 245° , yellow; *HCl* salt, m. 160° ; HI salt, sulfate; picrate, yellow. Me ester of the 6-MeO deriv. of V, m. 100° . Hydrazide (VII) of V (6.8 g. from 7 g. of the Me ester refluxed with $\text{N}_2\text{H}_4\text{-H}_2\text{O}$), m. 158° ; *HCl* salt. 6-MeO deriv. (VIII) of VII (6.5 g. from 7 g. of the ester), faintly yellow, m. 116° . Azide (IX) of V, from VII in 0.5 N HCl at -5° with cold 0.5 N NaNO_2 , brown smeary ppt; 6-MeO deriv. (X). $\beta\text{-}[2\text{-Phenyl-4-quinolyl}]\text{ethylurethane}$ (XI) (6.3 g. from the IX above refluxed 1 hr. in alc.), m. 72° . Bis- $\beta\text{-}[2\text{-phenyl-4-quinolyl}]\text{ethylurea}$ (3.8 g. from 4 g. IX boiled 0.5 hr. with H_2O), m. 175° . 6-MeO deriv. (XII) of XI (7.7 g. from 8 g. X), m. 125° . $\beta\text{-}[2\text{-Phenyl-4-quinolyl}]\text{ethylamine}$ (XIII), obtained as the di-*HCl* salt (5.8 g.), m. 158° , from 6 g. XI refluxed 8 hrs. with concd. HCl ; free base, light brown oil, solidifies 4° , darkens in the air or *in vacuo*; chloroplatinate, yellow, does not m. 270° ; picrate, yellow. 6-MeO deriv. of XIII, m. 54° ; di-*HCl* salt (5.6 g. from 6 g. XII), m. 209° ; sulfate; chloroplatinate, intensely yellow; picrate, golden yellow.

C. A. R.

Synthesis of symmetrical homotetrahydroisoquinoline. JULIUS V. BRAUN AND HANS REICH. *Ber.* 58B, 2765-7 (1925).—The lactam (*C. A.* 20, 391) of $o\text{-H}_2\text{NCH}_2\text{CH}_2\text{-C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ in somewhat more than 20 parts dry EtOH poured upon 1.5 parts Na yields almost 40% of sym-homotetrahydroisoquinoline (I), $\text{C}_8\text{H}_{11}\text{NCH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{C}_6\text{H}_4$,

b_{11} 115° , d_4^{19} 1.034, has a faintly basic odor, eagerly absorbs CO_2 from the air; *HCl* salt, m. 250° ; chloroplatinate, ochre-yellow powder, becomes discolored 230° , m. 253° (decompn.); picrate, light yellow, m. 220° ; quaternary methiodide, m. 227° ; NO deriv., m. $71-2^\circ$. From the residue from the steam distn. of I is obtained $o\text{-H}_2\text{NCH}_2\text{CH}_2\text{-C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{OH}$, b_{12} 180° , characterized as the di-*p-nitrobenzoate*, yellow, m. 153° .

Action of formaldehyde and secondary amines on acids with labile hydrogen atoms. C. MANNICH AND LEONHARD STEIN. *Ber.* 58B, 2659-62 (1925); cf. *C. A.* 18, 3360.—The reaction whereby $\beta\text{-NH}_2$ acids are formed from malonic acid derivs. and sec. amines and HCHO does not take place with $\text{PhCH}_2\text{CO}_2\text{H}$ but when the negative character of the Ph group is strengthened by the introduction of NO_2 groups the CH_2 group is sometimes so activated (*p-nitro-* (I) and 2,4-dinitrophenylacetic acid (II) that the reaction does take place. $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH}(\text{OH})\text{CO}_2\text{H}$ (III) can also be used, but no success was had with $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H}$, *m-* and *p-O}_2\text{NC}_6\text{H}_4\text{CH}(\text{OH})\text{CO}_2\text{H}, $o\text{-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{COCO}_2\text{H}$, $\text{HO}_2\text{SCH}_2\text{CO}_2\text{H}$, $\text{CCl}_3\text{CH}(\text{OH})\text{CO}_2\text{H}$ and *o-* and *p-HOC}_6\text{H}_4\text{CH-}**

PhCO₂H. α -[*p*-Nitrophenyl]- β -piperidinopropionic acid (IV) (16 g. from 16.2 g. I in 5 cc. H₂O neutralized with piperidine and allowed to stand some days at 35–40° with 10.1 cc. of 30% HCHO), decomp. 138–9°, sol. in acids and alkalis; 4 g. refluxed 2 hrs. in H₂O, the soln. being kept permanently approx. neutral by the addn. of HCl, gives piperidine and 1.9 g. α -[*p*-nitrophenyl]acrylic acid, m. 176–7°, sol. in alkalis and reprecipitated by acids, immediately decolorizes Br. With Sn and concd. HCl 2.78 g. IV gives 2.5 g. of the *Nil*₂ acid *di*-HCl salt, m. 213° (decompn.), can be diazotized normally and coupled with 2-C₁₀H₇OH to a blood-red azo dye, but the diazo compd. cannot be converted into the HO acid by boiling. α -[*p*-Nitrophenyl]- β -dimethylaminopropionic acid (1.4 g. from 1.8 g. I), m. 167–8°. β -Methylamino homolog (1.6 g. from 5.4 g. I), decomp. about 177°, sol. in mineral acids and alkalis; HCl salt, decomp. 170°; phenylacetyl derivative, prepd. with PhCH₂COCl in NaOH, m. 175°. 1,3-Dipiperidino-2-[2',4'-dinitrophenyl]propane (1.55 g. from 2.3 g. II, piperidine and HCHO, CO₂ being evolved in the reaction), golden yellow, m. 133–4°; *di*-HCl salt, decomp. 144°. 1,3-Bisdimethylamino analog, yellow, m. 85–6°. 1,3-Bisdiethylamino compd., yellow-brown oil; the HCl salt also does not cryst.; picrate, decomp. 165–6°. α -[*o*-Nitrophenyl]- α -hydroxy- β -piperidinopropionic acid (2.2 g. from 1.97 g. III), crystals with 1 H₂O, decomp. 109°, has a neutral reaction and dissolves in HCl and alkalis.

Some degradation products of digitogenin. A. WINDAUS AND S. V. SHAH. *Z. physiol. Chem.* 151, 86–97 (1926).—Oxidation of digitonic acid with 5 parts of fuming HNO₃ gives 20% of an acid C₂₂H₃₁O₁₀N (I), which decomp. 242° and is probably the HNO₃ ester of a lactol. Its *di*-Me ester, m. 194–5° (decompn.) was prepd. by treatment with CH₃N₂. This splits out HNO₂ when warmed with KOH in MeOH and is converted thereby into resinous products. Oxidation of I with alk. KMnO₄ gives an acid C₂₂H₃₁O₁₁, m. 113°, then solidifies and m. 172°. Treatment of oxydigitogenic acid with HNO₃ gives 30% of an acid C₂₁H₃₁O₁₁N, m. 218–20° (decompn.), which also loses HNO₂ when warmed with alc. KOH. The *tri*-Me ester, m. 171°; when heated in a high vacuum at 250° it splits off HNO₂ with formation of a cryst. ester C₂₄H₃₅O₉, m. 142°, and this on sapon. yields a tribasic acid C₂₁H₃₁O₉, m. 215–6°. The ester C₂₅H₄₀O₉ (II), previously obtained from the mother liquor in the prepn. of digitogenic acid, when refluxed with AcOH and H₂SO₄ gave 25% of an acid *di*-Me ester C₂₈H₄₀O₉.H₂O, m. 125°. Sapon of II with AcOH and HCl gave the *mono*-Me ester, m. 201°. By refluxing II with AcOH and HI an impure product (III) contg. I and m. 240–50° was obtained; its *tri*-Me ester C₂₉H₄₀O₉ is dimorphous, m. 122° and 105°. Removal of I from III by Zn dust gave a tribasic acid C₂₆H₃₅O₈, m. 273–4°; Me ester, m. 125–6°. A. W. DOW.

Infra-red absorption of the N-H bond (SALANT) 3. Polysaccharides (XXXIII). Enzymic decomposition of artificial silk and of native cellulose (KARRER, *et al.*) 11A. Influence of temperature on the reciprocal solubility of the monoalkyl ethers of ethylene glycol and water (COX, CRETCHER) 2.

Organic Synthesis. Vol. 5. New York: J. Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 110 pp. 7s. 6d.

Methanol, etc. BADISCHE ANILIN & SODA FABRIK. Brit. 237,030, April 28, 1924. Catalysts for producing MeOH and other products by reaction of C oxides with H at elevated temps. under pressure comprise a mixt. of 2 or more metals, the oxides of which can be reduced to the metal by H or CO at ordinary pressure and at a temp. below 550°. Fe, Co and Ni are excluded as are also mixts. with metals of the 4th to 7th periodic groups or B. Cu, Ag, Pb, Zn and Cd are suitable metals; carriers and addns. such as K₂CO₃ may be present. MeOH may be formed under 150 atm. pressure.

Separating butyl alcohol and water. A. STEVENS. U. S. reissue 16,267, Feb. 16, 1926. See original pat. No. 1,394,232 (C. A. 16, 423).

1-Nitro-2-methylantraquinone. H. E. FIERZ. Brit. 237,100, July 28, 1924. See U. S. 1,540,467 (C. A. 19, 2210).

Acetylsalicylic acid. KEROL Co. Brit. 237,574, July 22, 1924. Salicylic acid is dissolved in an inert solvent such as dry Et_2O and ketene passed into it until the soln. is satd. On evap. the ether, needle-like crystals of acetylsalicylic acid are obtained.

Ketenes. KEROL Co. Brit. 237,573, July 22, 1924. Ketenes are produced by thermal decompn. of acetone, Ac_2O or similar compds. in the presence of metallic sulfates, preferably those which are not decomposed by heating to 700° such as the sulfates of Cr, Mn, Al, Ca, Ba, Sr, Mg and Ag. A temp. of about 635° may serve for the decompn.

Acetic anhydride. BRITISH CELANESE, LTD., and W. BADER. Brit. 237,302, Jan. 24, 1924. Acetone is caused to react on CO_2 in excess, preferably under pressure. In the presence of H_2O HOAc is formed. Temps. of 250 – 450° may be used and there may be present substances such as oxides and carbonates of Li, Ca, Ba, Sr, Mg, Th, Zr, Ti, Ce and Sn, charcoal, SiO_2 , port. cement or metallic Cu.

Acetic anhydride. KEROL Co. Brit. 237,575, July 22, 1924. Ketene is passed into HOAc to produce Ac_2O without secondary products. By additional supply of ketene a soln. of ketene in the anhydride is obtained. Glacial HOAc is used.

Barbituric acid pyrazolone compounds. F. HOFFMAN-LA ROCHE & Co., AKT.-GES. Brit. 237,590, July 23, 1924. Mol compds. of dialkyl- or arylalkylbarbituric acid and 1-phenyl-2,3-dimethyl-4-dimethylamino-5-pyrazolone are produced by intimate mixing. Compds. from dipropyl-, diethyl- and phenylethylbarbituric acids are described.

Barbituric acid derivatives. L. THORP. U. S. 1,576,014, March 9. Malonic esters are condensed with urea in abs. alc. soln. by means of Na, by distg. the alc. out of the mass without preliminary refluxing. This serves to produce high yields without decompn. of the product.

Formamide. BADISCHE ANILIN & SODA FABRIK. Brit. 237,528, March 14, 1925. The vapor of NH_4 formate or formic acid together with free NH_3 , with or without H_2O , is passed over a contact mass (preferably a dehydrating material such as bauxite) at temps. of 100 – 200° .

Sodium formate. M. HENDERLI. U. S. 1,574,875, March 2. CO is caused to react upon dil. Na_2SO_4 solns. in the presence of $\text{Ca}(\text{OH})_2$ or other alk. earth metal hydroxide and further Na_2SO_4 is added to maintain a const. low concn. which may be about 5–6%. Cf. C. A. 19, 3490.

Methylene chloride. E. R. BRODTON. U. S. 1,575,967, March 9. A fluid consisting mainly of methylene chloride is prepd. by redistn. of crude products to obtain a product which is non-inflammable, non-corrosive of brass, Cu, Al and Fe and which may be used for driving engines, extinguishing fires, etc.

"Fixing" of ethylene by sulfuric acid. A. A. L. J. DAMIENS, M. C. J. E. DE LOISY and O. J. G. PIERRE. U. S. 1,574,796, March 2. In rapid fixing of C_2H_4 for production of ethylsulfuric acid and Et_2SO_4 , there is added to H_2SO_4 of about 66° Bé. as catalyzer, a cuprous compd. such as Cu_2O and a gas contg. C_2H_4 is passed through this acid at a temp. of 0 – 50° , the catalyzer is sepd. from the acid, and the acid is dild. The Et_2SO_4 which floats on the surface of the acid is collected and the ethylsulfuric acid remains in soln.

Phenolphthalein. E. B. PUTT. U. S. 1,574,934, March 2. A bulky, substantially white, amorphous phenolphthalein is obtained by dissolving pure cryst. phenolphthalein in aq. NaOH soln., pptg. with HOAc and HCl and drying.

Organic derivatives of tin. C. OEGHSLIN. U. S. 1,573,738, Feb. 16. Ethylene chlorohydrin or other chlorohydrin is treated with SnCl_2 in the presence of NaOH or other alkali metal hydroxide, to produce $\text{HO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{SnO}_2 \cdot \text{Na}$ which may be isolated as a S deriv. by use of BaCl_2 and H_2S .

Clarifying saccharin liquors. I. H. MORSE. U. S. 1,573,733, Feb. 16. A soln. or suspension of a reagent such as lime is continuously sprayed into a film of the liquor, which is maintained in thin annular form by being given a swirling motion as it ascends in a cylindrical column.

Enzyme dialysis. O. WALTER. *Bull. acad. sci. Russie* [6] 1917, 1075-88. Collodion bags of any desired degree of permeability and diminished pressure in the outer soln. are utilized. By using tryptase from yeast, a slight lowering of the activity of the soln. (which might be caused by absorption) was found after dialysis. The whole of the N capable of reacting with formaldehyde and 98.5% of the total N were removed. B. C. A

Effect of X-rays on cholesterol content, hydrogen-ion concentration, freezing-point depression, and surface tension of blood. F. KONRICH AND E. SCHELLER. *Strahlenther.* 18, 263(1924).—The cholesterol content and the H-ion concn. of pathological human blood are not affected by X-radiation, the surface tension of the blood is practically unaltered; but the f.-p. depression of the serum is increased. X-radiation of animals lowers the H-ion concn. and the surface tension, but has no effect on the cholesterol content of the blood. B. C. A

Deposition, separation, and reabsorption of hemoglobin in the organism and their relation to the deposition of iron pigment. K. SHIMURA. *Virchow's Arch.* 24, 464 (1924).—Hemoglobin, given to dogs intravenously, was rapidly excreted. The sepsis is brought about by the kidneys, liver, gall-ducts and suprarenals; in the remaining organs the hemoglobin is stored up and decomposed into iron pigment. B. C. A

The alcoholic splitting of protein. I. CH. GRANACHER. *Helvetica Chim. Acta* 8, 784-91(1925).—Emil Fischer's conception that proteins are built up from amino acids is doubted in the light of recent work. There is the possibility that they are labile heterocyclic ring systems. 200 g. goose feathers autoclaved for 2 hrs. at 170-75° with 1 l. 95% C₂H₅OH yield (NH₄)₂CO₃ or NH₄CO₂NH₂ and NH₃(1.5-1.8% of total feather mass) on distn. and 173 g. of solid after heating on a water bath in a vacuum. Analysis of solid: Total N 14.95%, amino N 0.75%. About 2/3 dissolves in 5 times its mass of water. The soln. gives no ninhydrin reaction and only indistinct brown with CuSO₄ or NaOH. An ether ext. of the aq. soln. of solid from 500 g. feathers divides into 3 parts: (a) a solid which seps directly, 2.5 g., and contains diketopiperazine; (b) an ether soln. yielding 14 g. of sirup from which more crystals sep. on standing; (c) 30 g. of sirup sol. with difficulty in ether; it fractionated at 5 mm. pressure. The total distillate weighs 15 g. Fraction 130-40°: viscous oil sol. in H₂O; no color with either Cu(OH)₂ or ninhydrin; forms oily picrate with picric acid; analysis C 77.9, H 8.9, N 11.5%. After boiling with concd. HCl it gives an intensely positive ninhydrin reaction and a deep blue on boiling with CuCO₃. Fraction 180-200°: semi-solid in the cold; analysis total N 12.53, amino N 0.50%. Polypeptides of the acid amide type do not dissolve after autoclaving with alc. at 170-80° for 10 hrs. Benzoyl-diglycylglycine yielded no split products on heating for 4 hrs. at 175-85° with 1% alc. NH₄. Diglycylglycine yields an amorphous mass (probably a higher condensation product) and a cryst. substance which appears to be glycine anhydride on heating for 5 hrs. with 1% H₂S. M. BEBER

Polysaccharides. XXXIII. The enzymic decomposition of artificial silk and of native cellulose. P. KARRER, P. SCHUBERT AND W. WEHRLI. *Helvetica Chim. Acta* 8, 797-810(1925); cf. C. A. 19, 3278.—Differences in resistance to enzyme action are due to differences in phys. structure or in arrangement of micellae and thus of active surfaces. Velocity of hydrolysis depends on concn. of the enzyme as well as on the abn. amt. For comparable measurements relation of cellulose to vol. of mixt. must be kept const. To hydrolyze cellulose preps. that hydrolyze with difficulty within a reasonable time use the enzyme in the highest possible concn. At first the hydrolysis follows the same course as the decompn. of lichenin; next, it approaches a monomol. isotherm, and later (up to 50% decompn.) it follows Schütz's rule. Cotton and com. copper silks are easily acted on by cellulase from snail. Native cellulose hydrolyzed with difficulty and then only with high concns. of enzyme. The unit for cellulase varies, depending on whether it acts on pptd. or native cellulose and "small cellulase unit," used for pptd. cellulose, defined as amt. of cellulase which in 50 cc. at pH 5.28 and temp. 36° will bring about 20% hydrolysis of 1 g. of fibrous copper silk ("Zellwag") in 96 hrs. The enzyme is adsorbed by various aluminiferous earth preps. but not by kaolin. Considerable quantities are lost in dialysis because of adsorption by the membrane. Temp. begins

to inactivate the enzyme at 45–50°; considerable is lost at 55° and the inactivation is almost complete at 60°.

N. BEBER

The relation of human native serum to whole blood serum. II. The reality of refraction differences. W. STARLINGER AND U. STRASSER. *Biochem. Z.* **160**, 417–25 (1925); cf. *C. A.* **19**, 2231.—The differences in refractive index between native serum (that sepg. from plasma) and whole blood serum (that sepg. from whole blood) are very small.

F. A. CAJORI

Various inhibition phenomena in the enzymic cleavage of sucrose. HANS V. EULER AND KARL JOSEPHSON. *Z. physiol. Chem.* **152**, 31–54 (1926).—The view that enzyme reactions occur through the intermediate stage of enzyme-substrate compds., whose equilibria are controlled by the law of mass action, allows a classification of various inhibition phenomena which result from the addn. of other substances. Assuming that the velocity of an enzymic reaction is detd. partly by the concn. of enzyme-substrate compd. and partly by the decompn. velocity of such a compd., the inhibitions may be attributed to alteration of the concn. or to alteration of the decompn. velocity of the complex. Alteration of the concn. may be due to the affinity of the added substance, either for the enzyme portion or for the substrate portion of the complex. By changing the substrate concn., a change then occurs in the relative inhibition by the added substance. In the case of sucrase the effect would vary also according to whether the inhibitory substance is coupled to the glucose- or to the fructose-binding group of the enzyme. It should be possible by displacement of the substrate from the complex in such a way as to inhibit the enzyme action, to det. which of the two affinity positions was occupied by the inhibitor. Galactose, zymophosphate, and AcH alter the inhibition by glucose, but not that by fructose. The aldehyde sugar galactose is, therefore, bound to the same affinity group of the enzyme as glucose, notwithstanding the difference between the two sugars with respect to groupings around the 4th C and the location of the O bridge. The same holds true also for AcH and zymophosphate. Partial inactivation of sucrase by $m\text{-ClC}_6\text{H}_4\text{NH}_2$, followed by addn. of glucose or fructose, showed that sugars can react with amines, the reaction capacity being greater for aldoses than for fructose. In this case the addn. of glucose may bring about an activation by displacing part of the amine from the enzyme complex, up to the point where the sp. inhibitory effect of the glucose itself predominates. Fructose inhibits sucrase somewhat more than glucose. A mixt. of glucose and fructose, however, is more inhibitory than the mol. equiv. of fructose alone. Galactose diminishes the inhibition by glucose but not that by fructose. Na zymophosphate and glucose together show a smaller inhibition than glucose alone, while the reverse is true with respect to fructose inhibition. This indicates that the esterified hexose has more of a glucose- than a fructose-like constitution. Simultaneous inhibition by AcH and fructose is greater than that by AcH and glucose. After partial inhibition by $m\text{-ClC}_6\text{H}_4\text{NH}_2$, the activity of sucrase may be appreciably restored by glucose, whereas it is further diminished by fructose. When the glucose and the amine solns. were mixed 15 hrs. before the test, the enzyme showed greater activity than when the freshly prepd. mixt. was tested. Allowing for the inhibitory action of glucose, the reactivation in this case amounted to 50%. Maltose also has the property of reactivating sucrase after partial inactivation by the amine.

A. W. DOX

The muscle pigment and MacMunn's myohematin. II. O. SCHUMM. *Z. physiol. Chem.* **152**, 55–65 (1926).—Immediately after death the heart muscle of mice and rats shows a distinct content of the pigment or pigment mixt. which MacMunn designated as myohematin. Spectroscopically it is identical, or nearly so, with Keilin's cytochrome of yeast. Myochrome and hemoglobin probably contain the same porphyratin. MacMunn's myohematin, which is probably a mixt. of several porphyratin carriers, contains, predominantly at least, a porphyratin which is not identical with the Fe complex of coproporphyrin.

A. W. DOX

The affinity relations of sucrase. VII. Influence of preliminary treatment of yeast on the affinity constant of sucrase. 1. HANS V. EULER AND KARL JOSEPHSON. *Z. physiol. Chem.* **152**, 66–87 (1926).—Assuming that a transition from a precursory form into active enzyme occurs under the influence of fermenting sugar, it follows that the development of active sp. groupings necessary for enzyme action is such as to meet sp. requirements. It should, therefore, be possible, by the application of various substrates in a preliminary treatment, to obtain sucraes of different specificity. Thus a preliminary treatment by sucrose (fructose plus α -glucose) should exert a somewhat different influence on the constitution and configuration of the newly formed sp. substrate-binding groups of the enzyme than a similar treatment with either glucose (α - or β -form) or fructose alone. After preliminary treatment with sucrose or α -glucose

the affinity of the sucrase for α -glucose increases, whereas the affinity for β -glucose or fructose shows no such increase. While the sucrase from untreated yeast showed only a slight affinity for α -glucose as compared to that for fructose, a preliminary treatment with α -glucose yielded a sucrase with even stronger affinity for α - than for β -glucose and nearly the same affinity for fructose. Along with the increased affinity between sucrase and α -glucose a slight but definite increase in affinity between enzyme and sucrose seems to occur. The fact that yeast when cultivated on different sugars develops sucrase with more or less pronounced sp. affinities supports the possibility of the existence of various sucraes with varying inverting capacities. In explanation of the varying affinity consts. for fructose or glucose, two assumptions are valid: (1) at each affinity grouping the preliminary treatment alters the sp. attraction; (2) the relative number of fructose- or glucose-binding affinity groupings of the enzyme are altered. It is probable that in the living cell a quant. relationship exists between the sugar on the one hand and the affinity groups of the plasma on the other hand. Preliminary treatment affects the different enzymes of the organism to a very unequal degree, as shown by a comparison of inversion velocity with fermentation velocity. It cannot be assumed, however, that sucrase presents an exception in the sense that its two affinity consts. are altered to unequal extents by the preliminary treatment, but rather that the enzyme being adjusted to an equil. mixt. can undergo a change in its affinities through the influence of altered concns. of the substrate components.

A. W. DOX

The kinetics of ester cleavage by liver lipase. NOGAKI. *Z. physiol. Chem.* 152, 101-18(1926).—Lipase combines with the ester as well as with the cleavage products. In the sapon. of esters the amt. hydrolyzed is only approx. proportional to the time. The course of the reaction is not the same for all esters. After an initial steep drop or a slight rise the reaction velocity decreases to the end of the reaction. This decrease is due not to successive destruction of several enzymes of different resistance, but to a binding of the cleavage products; at alk. reaction by the alc., at acid reaction by alc. and acid. Since the binding velocity of alcohol-enzyme is less than that of ester-enzyme, the extent of the inhibition is dependent on the enzyme concn. as well as on the reaction temp. The more slowly the reaction proceeds, the more pronounced is the inhibition. The form of the reaction curve is therefore dependent, not only on the affinity of lipase for the ester and its cleavage products, but also on the velocity at which the sapon. proceeds, and this in turn on the enzyme concn. and temp.

A. W. DOX

Synthesis and fermentation of glycogen by maltase-free yeast. ALFRED GOTTSCHALK. *Z. physiol. Chem.* 152, 132-5(1926).—The yeast *Saccharomyces Ludwigii*, which contains no maltase, synthesizes as well as ferments glycogen. Cultivated on a glucose-salt medium, it builds up glycogen which again breaks down during autolysis. Hence, maltase is not in this case an intermediate product in the fermentative degradation of glycogen. The fact that by combined action of α - and β -amylase from one and the same maltase-free organism the glucoside linkages in the glycogen mol. are bound and broken points to the absence of maltose linkages in this polysaccharide.

A. W. DOX

Biochemical synthesis of fumaric acid from pyruvic acid. ALFRED GOTTSCHALK. *Z. physiol. Chem.* 152, 136-43(1926).—The mold *Rhizopus nigricans* when cultivated on a synthetic medium contg. pyruvic acid as the sole source of C produced in two months 32% of the theoretically possible amt. of fumaric acid, assuming that two mols. of AcCO_2H yield 1 mol. of fumaric. AcOH was also formed. The mechanism of the synthesis is believed to be $\text{AcCO}_2\text{H} \rightarrow \text{AcH} + \text{CO}_2 \rightarrow \text{AcOH} \rightarrow (\text{CH}_2\text{CO}_2\text{H})_2 \rightarrow \text{fumaric acid}$. Pyruvic acid is probably an intermediate stage in the fermentation of carbohydrate to fumaric acid.

A. W. DOX

Remark on paper III on coproporphyrin synthesis by yeast. HANS FISCHER. *Z. physiol. Chem.* 152, 144-5(1926); cf. *C. A.* 20, 769.—*Saccharomyces ananensis*, like com. yeast, produces hemin and traces of coproporphyrin when grown on beer wort. The cytochrome content is not altered by vigorous growth on media free from blood pigment and porphyrin. It is probable that the substance is synthesized directly from the sugar and inorg. salts of the medium. The hemochromogen spectrum in the pyridine ext. from plants, especially yeast and beans, was corroborated.

A. W. D.

The question of zymase formation and co-enzyme action. A. LEBEDEV. *Z. physiol. Chem.* 152, 146(1926).—Polemical with Euler and Nilsson (*C. A.* 20, 211).

A. W. DOX

The rennet-like action of pepsin. RYOICHI AKIBA. *Keio Ig., Tokyo* 2, 1387-91 (1922); *Japn. J. Med. Sci.* 2, 24.—The rennet-like action of pepsin on milk may be caused by the autocatalysis of pepsin itself. At the time when pepsin coagulates

milk, one can find a rennet-like enzyme of

The chemical constituents of tears. IV. 1922, 551-62; *Japn. J. Med. Sci.* 2, 15.—It is nearly 3 times that in serum and about half is nearly equal to that in serum and slightly more and Mg content in tears are lower than those in s

Enzymic splitting of dipeptides. I. H. v. EULER AND KARL JOSEPHSON. *Ber.* 59B, 226-33(1926).—*Erepsin* was prepd. by extn. of the intestinal mucosa of the pig with glycerol for 2 days and pptn. of the filtered ext. with alc. The reaction coeff for the splitting of *glycylglycine* was directly proportional to the amt. of enzyme used. The max. activity is at pH 8.0. Previous theoretical considerations (*C. A.* 17, 3034) are substantiated. ARTHUR GROLLMAN

Activity and iron content of highly active catalase preparations. S. HENNICHES. *Ber.* 59B, 218-25(1926).—The liberation of O from H_2O_2 by liver catalase prepd. by the method of *C. A.* 19, 84 was detd. The O liberated by preps. of different activity is not proportional to their Fe content. The oxidation of *alanine* in the presence of blood charcoal gave an activity per mg. of Fe content much lower than that obtained with liver catalase. The degree of poisoning of the catalase by *HCN* in varying concns. was detd. The view that the mechanism of this poisoning involves an adsorption of the catalytically active Fe is not supported. ARTHUR GROLLMAN

Pancreatic function. I. The determination of pancreatic enzymes. EDWARD HOLLANDER AND J. M. MARCUS. *Arch. Internal Med.* 36, 585-91(1925).—The linear relation between enzyme concn. and velocity of hydrolysis, on which clinical detns. are based, obtains only for *amylpsin*, for which the reversibility of the hydrolytic process is negligible. A linear relation may be obtained for *trypsin* and *steapsin* by applying Hedin's "time law." The time required to neutralize the same quantity of 0.1 N NaOH (phenolphthalein) in a certain quantity of substrate contg. varying amts of the enzyme is inversely proportional to the enzyme concn. The NaOH concn. is so chosen as not to inhibit the enzyme action. MARY JACOBSEN

The preparation of yeast glycogen. TAKEO YOKOYAMA. *Beitr. Physiol.* 3, 95-110(1925).—Yeast prepd. by killing fresh brewer's yeast rapidly and drying *in vacuo* at 100° is refluxed 30 hrs. with a 50% KOH until the I reaction of the residue almost disappears. The glycogen obtained by pptn. with 96% alc. is freed from gum substances with Na-free Fehling soln. and, if necessary, from proteins with Brücke's soln. It is further purified by repeated pptn. with 60% alc. from a slightly acid (HCl) soln. and finally pptd. with 96% alc. and washed with 66% alc. contg. a few drops of AcOH. Analysis: C 44.32%, H 6.65%, ash 0.261%, $[\alpha]_D$ 192. Inversion (Allihn): 97.2 to 98%. MARY JACOBSEN

The blood pigment and a few complex ferro salts. W. KÜSTER. *Chemie der Zelle u. Gewebe* 12, 1-21(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 672. MARY JACOBSEN

Are myelins present in the normal subcutaneous fat of man and in lipomas? ARIBERTO D'ARGENIO. *Folia med.* 10, 809-30(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 512-3(1925).—The subcutaneous fat of man and cow is free from myelin substances, if contamination with blood, never or connective tissue is avoided. Myelin substances were found in lipomas, partly decomposed with cholesterol formation in the case of CH_2O preps. The hydrolysis of the ether ext. led to a product which reduced Fehling soln. but could not be identified as protagon. The extn. method is more reliable for the detection of myelins than the histological staining methods. M. J.

The influence of medicaments on the sedimentation velocity of erythrocytes. S. HARA. *J. Orient. Med.* 2, 191-4(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 279(1925).—The tabulated results show that the sedimentation velocity is diminished by digifolin, digalen, spartein sulfate and $BaCl_2$ and not influenced by caffeine. MARY JACOBSEN

Occurrence and detection of organic skeleton substances in animals. GEORG KUNKE. *Z. vergl. Physiol.* 2, 233-53(1925); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 824.—Chitin, spongin, cornein, conchin and cellulose are discussed. MARY JACOBSEN

Vital staining in the liver of different classes of vertebrates. J. KRAFT. *Z. Zellen u. Gewebelehre* 1, 517-22(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 370.—Study of trypan blue fixation after repeated introduction of small doses into the abdominal cavity. In fishes the capillary epithelium did not store the dye, although the doses were larger than those given to mammals and the dye has been undoubtedly supplied to the liver. The interstitial tissue of the kidneys showed a considerable fixation of the dye followed

by staining of epithelial granula. Frogs, birds and, among mammals, the mouse show fixation of trypan blue in the liver cells.

MARY JACOBSEN

Diffraction in biologic structures. A. PIJPER. *S. African Med. Record* 23, 453(1925); *J. Am. Med. Assoc.* 86, 154.—The principles underlying the use of bacillary surface growths as diffraction gratings are discussed. The technic of measuring the diam. of bacilli by means of their diffraction spectra is indicated. The av. diam. of bacilli of a given strain is an unvarying biologic character. Changes in the diam. of the red blood cells can be measured by this method.

I. W. RIGGS

Isoelectric points of various proteins. FRANK A. CSONKA, JOSEPH C. MURPHY AND D. BREESE JONES. *J. Am. Chem. Soc.* 48, 763-8(1926).—The isoelec. points of a large no. of proteins have been detd. by shaking buffers having a p_H range from 4 to 6.8, with an excess of the protein investigated and pptg. the dissolved protein in the clear filtrate with tungstic acid. The Sørensen value of the buffer filtrate in which was produced the least turbidity is taken as the isoelec. point of the protein. The results show that those proteins having the greater soly. in H_2O have the lower isoelec. points and that a correlation exists between the isoelec. points of proteins of the same group. The isoelec. points of albumins were found to range between p_H 4 and p_H 5, those of globulins from 5 to 5.5 and those of prolamines from 6 to 6.5. Proteins requiring the greater quantity of $(NH_4)_2SO_4$ for their pptn. from saline solns. have lower isoelec. points than proteins which require less. Thus the β -globulins have lower isoelec. points than the α -globulins. Albumins were found to be more sol. in the buffers used, on the alk. side of their isoelec. points, while globulins showed greater soly. on the acid side.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Fairhall (chromate) method for minimal amounts of lead in fecal specimens. ANON. *Ind. Eng. Chem.* 18, 431-2(1926).—In the study of the hazards involved in the distribution and use of gasoline treated with Pb tetraethyl, great care was taken in the detn. of traces of Pb in the feces. The method used was a modification of the Fairhall method; it consisted in drying the feces, ashing, extg. with 6 *N* HCl, filtering, ashing the residue with tartaric acid and HCl, filtering, combining the 2 filtrates, pptg. with H_2S in barely acid medium, dissolving the ppt. and repptg. twice with H_2S , dissolving the third ppt. in HNO_3 , evapg., filtering off any S, pptg. as $PbCrO_4$ in very dil. $AcOH$, and titrating iodometrically the $PbCrO_4$ ppt.

W. T. H.

Buffered water for the Romanowsky-Giemsa stain. MICHAEL BALINT. *Klin. Wochschr.* 5, 147-8(1926).—The stains are dild. with a $M/50$ – $M/400$ phosphate buffer of p_H 6.8-7.0. This p_H gives the sharpest differentiation.

MILTON HANKE

Histological demonstrations of calcium by the method of Rabl. E. FREUDENBERG. *Klin. Wochschr.* 5, 64-6(1926).—Rabl claims to be able to differentiate 2 kinds of Ca in tissue by immersing the tissue in a neutral soln. of $(NH_4)_2C_2O_4$. Insol. bone Ca, present as $Ca_3(PO_4)_2$ and $CaCO_3$, is said to remain unchanged; sol. Ca becomes fixed as CaC_2O_4 . This is theoretically improbable and can be shown by expt. to be untrue. Bones immersed in neutral $(NH_4)_2C_2O_4$ show a conversion of at least 33% of their insol. Ca into CaC_2O_4 . It is, therefore, impossible to differentiate sol. from insol. Ca by the method of Rabl. See also Böhming (*C. A.* 20, 234).

MILTON HANKE

Histological demonstration of soluble calcium compounds. C. R. H. RAHL. *Klin. Wochschr.* 5, 365(1926).—An unconvincing answer to the criticism of Freudenberg (preceding abstract).

MILTON HANKE

The detection and occurrence of chitin. PAUL SCHULZE. *Z. Morphol. Ökol. d. Tiere* 2, 643-66(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 208(1925).—A detailed description of the microchem. detection of chitin.

MARY JACOBSEN

Spectroscopic methods for the detection of blood in feces. SNAPPER. *Arch.*

maladies appar. dig. nutrit. 14, 677-704(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 429(1925).

MARY JACOBSEN

New methods of silver impregnation of nerve fibers as applied to series section in paraffin. WALTER FREEMAN. *Riv. patol. nerv. ment.* 29, 89-92(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 779(1925).

MARY JACOBSEN

The sulfosalicylic acid method in the determination of pepsin action. R. W. SEUFFERT AND E. MOHR. *Beitr. Physiol.* 2, 275-82(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 800(1925).—The time required for the decoloration of sulfosalicylic acid-serum depends on the age of the substrate. It increases inversely with the enzyme content but at a much higher rate and depends on the HCl content. A pepsin soln. neutralized by CaCO_3 does not regain its activity by addition of HCl. Numerous control expts. are necessary.

MARY JACOBSEN

Manometric determination of cellular metabolism in serum. OTTO WARBURG. *Biochem. Z.* 164, 480-503(1925).—Modifications of the original method (C. A. 19, 1720) are described which adapt it to the study of cellular metabolism where the glycolysis is small as compared to the respiration. When m mg. tissue (dry substance) develop in t hrs. x cu. mm. O_2 , CO_2 or lactic acid, the following quotients are obtained: $Q_{\text{O}_2} = x_{\text{O}_2}/mt$; $Q_{\text{CO}_2} = x_{\text{CO}_2}/mt$; $Q_M = x_M/mt$; $Q_S = x_M + x_{\text{CO}_2}/mt$, where M is lactic acid and S serum. From these quotients are calcd. in % by wt.; oxygen consumption: $Q_{\text{O}_2}(32/22,400) 100 = Q_{\text{O}_2} \times 1.43 \times 10^{-3} \times 100$; CO_2 production: $Q_{\text{CO}_2}(44/22,400) 100 = Q_{\text{CO}_2} \times 1.96 \times 10^{-3} \times 100$; lactic acid formed: $Q_M(90/22,400) 100 = Q_M \times 4.02 \times 10^{-3} \times 100$.

S. MORGULIS

Contribution to the p_H determination in blood. A new hydrogen electrode. G. ETIENNE, M. VERAINE AND M. BOURGUAUD. *Compt. rend. soc. biol.* 93, 765-6(1925).—The object of this instrument is to secure a const. and low value for Michaelis' factor $a = \text{vol. H}_2/\text{vol. serum}$. A pipet provided with a glass stopcock has a capacity of exactly 7.5 cc. The vol. 0.05 cc., i. e., $1/150$ of the vol. of the pipet, below the stopcock is marked by a line on the stem. Between this line and the stopcock a Pt wire is fused through the stem and bent so the end inside reaches 1 mm. below the line. Plasma is obtained with the usual precautions practiced in the p_H detn., and the bulb and its connecting tubes are completely filled with this plasma. The pipet is then attached to a H generator and H is slowly run in until the plasma reaches the mark below the stopcock (0.05 cc). The stopcock is then closed and the free end likewise closed with the finger and the contents are thoroughly mixed. The pipet is plunged together with a N or 0.1 N calomel electrode into the connecting vessel kept in a thermostat at 37° and the p_H measured by the c. m. f. as usual.

S. MORGULIS

C—BACTERIOLOGY

A. K. BALLS

Rapid method of preparation of silica-gel for bacteriological cultures. M. SOUL-REYRE. *Ann. Brass. et Dist.* 23, 371-2(1925); *J. Inst. Brewing* 31, 471-2; *Analyst* 50, 629-30.—The principle employed is the elimination of the K contained in the silicate used as the slightly sol. bitartrate, this salt being removed by filtration. One hundred cc. of a soln. of K silicate (sp. gr. 1.057) are poured rapidly into a mixt. contg. 40 cc. of 20% tartaric acid soln., 1 cc. of 84% phosphoric acid soln. and 1 cc. of H_2SO_4 dild. with an equal vol. of water. After 5 mins. pptn. is accelerated by stirring, the ppt. allowed to settle, and the supernatant liquid filtered, the filtrate being designated A . A second soln., B , is prepd. by mixing 2 vols. of K silicate soln. (sp. gr. 1.085) with 1 vol. of 5% KOH soln. For the culture of yeasts a suitable medium is obtained by sterilizing separately at 115° for 10 min. After cooling in a stream of water, liquids (a), (b) and (c) are mixed in the following order: (a) 100 cc. of soln. A and 50 cc. of beer wort; (b) 100 cc. of sugar soln. or other nutritive medium; (c) 50 cc. of soln. B ; and they are then transferred immediately to sterile Petri dishes or test tubes. Modifications of this medium are described for use in the culture of bacteria and N-fixing organisms.

H. G.

Bacteriological examination of material containing *B. proteus*. ALBRECHT SCHUPACK. *Klin. Wochschr.* 5, 67-8(1926).—Prep. an immune serum by injecting guinea pigs with several strains of *B. proteus*. It should have a titer of approx. 1:6000. Preserve by mixing with an equal vol. of 0.5% phenol. Mix 0.2-0.3 cc. of this serum with 10 cc. of liquefied agar medium and slant as usual. This medium is then inoculated with the material to be investigated. *B. proteus* is agglutinated; the other bacteria develop normally. In this way an overgrowth by *B. proteus* is avoided.

M. H.

Bacteriology of the duodenum. J. OLIVET. *Klin. Wochschr.* 5, 307-10(1926).—

The duodenum is usually sterile. It is always sterile when the concn. of gastric HCl is normal or above normal. The duodenum becomes infected in diseases that are associated with hypoacidity or anacidity. The invading organisms, chiefly colon bacilli, are not usually classed as pathogenic; but they may become so if they invade the bile duct, cystic duct or gall bladder.

MILTON HANKE

The behavior of bacteria to nuclear staining. K. VORR. *Z. ges. exper. Med.* 47, 183-92(1925).—Nuclear staining depends on the ability of nucleic acids of the type of thymonucleic acids to stain with acid fuchsin after partial hydrolysis, but not without hydrolysis. By the use of this method, nucleic acid of the type of thymonucleic acid may be demonstrated in various bacteria and in the nuclei of trypanosomes.

HARRIET F. HOLMES

The chemical composition of *Spirocheta pallida*. JOSEF SCHUMACHER. *Dermatol. Wochschr.* 79, 1494-7(1924); *Ber. ges. Physiol. exper. Pharmacol.* 30, 322(1925).—The O content of *Spirocheta pallida* is very low because of the absence of nucleic acids. The main constituent is a Gram-negative lipoprotein.

MARY JACOBSEN

Gum formation by bacteria. FERNBACH. *Sucre Belge* 44, 639(1925).—*Leuconostoc dextranicus* attacks only dextrose giving dextran, which upon hydrolysis regenerates dextrose. This dextran has no reducing power. *Leuconostoc* produces gums only from dextrose which it previously derives from saccharose. It forms no gum in the presence of sugar previously inverted, nor from glucose or levulose. The yield of dextran is at most 10% while the yield of levulosan may reach 50%. It has also been confirmed that the levulosan-producing bacterium produces no gum except from nascent levulose. Sucrose is incapable of yield gum directly.

T. M.

The influence of lipid solvents on spore formation in aerobic bacteria. S. MICHALOWSKY. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 17-25(1925).—Cultures of aerobic spore formers including *B. subtilis*, *B. megatherium*, *B. mesentericus*, *B. anthracis* and *B. chauwei* were grown on agar at 32 to 34° and exposed sealed to the fumes of a long list of substances including various alcs., ethers, aldehydes, acids, ketones, benzene, toluene, etc. In most instances lipid solvents increased spore formation and other substances did not.

JOHN T. MYERS

Conditions affecting aerobiosis and anaerobiosis of bacteria. E. HOEN. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 25-31(1925).—The amt. of free O required by a given bacterial species increases with the amt. of available food material.

J. T. M.

The action of vertebrate hormones on bacterial growth. K. FUJITA. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 31-8(1925).—The effect of various hormones on the rate of growth of *B. coli* was studied. Adrenaline and weak thyroid ext. inhibited growth, pituitrin and parathyroid stimulated it, and thymus and insulin had no demonstrable effect.

JOHN T. MYERS

The relationship of urea bacteria to organic compounds. L. RUBENTSCHIK. *Centr. Bakt. Parasitenk., II Abt.,* 65, 1-15(1925).—The urea bacteria of Chadjibeylinus will grow and ferment urea in protein-free media, with urea as the only source of N and various N-free compds. such as starch and dextrin as the source of C. The growth energy was low in protein-free media. There is a parallelism between the energy of growth and that of urea fermentation. Urea can serve as a source of N but not of C. Each species of urea bacteria has an optimum org. compd. as a source of N. This suggests the possibility of a number of different species.

JOHN T. MYERS

The dependence of the rate of denitrification on the reaction of the medium. T. M. SACHOROWA. *Centr. Bakt. Parasitenk., II Abt.,* 65, 15-35(1925).—Denitrification by the bacteria of Iterson and by *Bacterium stutzeri* is dependent on the reaction of the medium. The optimum for the bacteria of Iterson is p_H 7 to 8.2, for *B. stutzeri*, 7.6. The acid limit for the reduction of HNO_3 is p_H 5.2 and the alk. limit, 9.8. The same conditions apply to the reduction of nitrites. The presence of NO_3 slows NO_2 reduction. Reduction of HNO_3 is more vigorous in the presence of $Sr(NO_3)_2$ than in that of KNO_3 because CO_2 from the destruction of cellulose is pptd. as water insol. compds. by $Sr.$ and not by $K.$ Hence the medium does not grow rapidly alk. in the presence of $Sr.$

JOHN T. MYERS

Bacterial sulfur oxidation in pond soils and its practical value. H. FISCHER. *Centr. Bakt. Parasitenk., II Abt.,* 65, 35-42(1925).—Sulfate formation in pond soils is analogous to nitrification. The process depends on the p_H of the water and soil and on the nature of the org. compds. present. The buffer action of soil carbonates and the adgn. of S or H_2S has a marked effect in such soils. The formation of SO_4 ions brings into soln. considerable amts. of soil phosphates so necessary to fish life.

JOHN T. MYERS

A green bacterium. J. SACK. *Centr. Bakt. Parasitenk., II Abt.,* 65, 113-6(1925).

A spore-forming bacterium was found in soils. It produced a blue green pigment which was a mixt. of yellow and blue. The blue pigment crystallizes in plates. It can use N but not C from inorg. compds.

Sphaerotilus natans. J. SACK. *Centr. Bakt. Parasitenk., II Abt.*, 65, 116-8(1925).—These bacteria cannot assimilate free N. They fail to grow in cond. water contg. K_2HPO_4 and glucose. There is almost no growth with KNO_3 , $NaNO_2$, $(NH_4)_2SO_4$, asparagine, tyrosine, or glycocoll as a source of N. They depend on protein for N. NH_3 but not free N is produced.

The influence of bacterial fluorescein on protozoa. H. ZIKES. *Centr. Bakt. Parasitenk., II Abt.*, 65, 128-30(1925).—The fluorescent substances produced by bacteria have an inhibiting photodynamic effect on certain protozoa.

Chalk bacteria and other chalk-precipitating fungi. H. MOLISCH. *Centr. Bakt. Parasitenk., II Abt.*, 65, 130-9(1925).—There are marine bacteria which can ppt. cryst. $CaCO_3$, the crystals being spherical or hourglass in shape. The pptn. is so marked that agar or gelatin colonies become turbid with a definite corona around them. Sea water in a medium will serve as a source of Ca, but the addn. of Ca in any form as chloride or acetate hastens the pptn. They produce NH_3 from org. matter which combines with CO_2 and then reacts with Ca. Many strains of these bacteria were isolated from sea water and pond and lake soils, and also an actinomycete from the air. They probably play an important part in nature. Some species produce oxalic acid which ppts Ca as the oxalate.

The utilization of non-protein sources of nitrogen by the micrococci. G. J. HUCKER AND L. F. RETTGER. *Centr. Bakt. Parasitenk., II Abt.*, 65, 273-7(1925).—The micrococci, while they produce luxuriant growth on complex substances, also have the power to utilize more simple forms of N. However, they have become either too specialized to use chem. pure amino acids or have lost the power to produce enzymes which would enable them to utilize such forms of N. They thus differ from the more saprophytic colon typhoid group, which in many cases grows abundantly on pure amino acids as the only source of N. With NH_4 phosphate as the only source of N, distinctly saprophytic strains cloud the medium, while the parasitic ones do not.

The germination of the conidia of Botrytis cinerea in solutions of various substances. K. STARITZSKY. *Centr. Bakt. Parasitenk., II Abt.*, 65, 291-7(1925).—Germination was studied in a variety of org. and inorg. substances. Solns. just strong enough to prevent sprouting swelled the spores so that the diam. was twice that of fresh conidia. In the presence of concd. solns. of many org. acids as citric, tartaric or lactic, abnormally thick irregular sprouts formed. Similar forms appeared with Na_2CO_3 , Na_2SO_4 and $ZnSO_4$. In dye solns. the sprouts remained uncolored.

A contribution to the dynamics of toxicity and the theory of disinfection. I. S. FALK AND C. E. A. WINSLOW. *J. Bact.* 11, 1-25(1926).—The mortality of *B. coli* in solns. of NaCl and $CaCl_2$ and in distd. water of varying p_H follows a generally logarithmic course and may be roughly described by the unimol. chem. equation. This relationship is not close or exact. Where disinfection does not follow a logarithmic course and is not described by the unimol. equation, the course may be sometimes described by the di-, tri-, or higher multimolecular reaction. When used in sufficiently low concn., NaCl and $CaCl_2$ may not only be non-toxic for *B. coli* but may stimulate growth and reproduction. The reaction between disinfectant and cell or cell constituents is probably highly complex.

The multiplication of yeasts and yeast-like fungi in synthetic nutrient solutions. E. W. TANNER, E. D. DEVEREUX AND F. M. HIGGINS. *J. Bact.* 11, 45-64(1926).—Fifty pure species of yeasts and 22 strains of yeast-like fungi multiplied rapidly in Fulmer and Nelson's medium F. over a period of 11 months. Growth was less in Ferml's medium and least in Nageli's. These organisms can develop in pure synthetic media if heavy inoculations are used, but growth is more rapid if "bios" or org. matter is present. Growth depends on a number of factors such as temp., acclimatization to a certain medium, purity of ingredients, chem. constitution of the medium, aeration and p_H . Absence of growth may be explained by variation in these factors. Postulation of "bios" or other hypothetical substance is not necessary.

Nitrification in the sea. B. ISSATCHENKO. *Compt. rend.* 182, 185-6(1926).—The conditions for bacterial nitrification in the Azov and Black Seas are discussed.

The interconvertibility of "rough" and "smooth" bacterial types. E. O. JORDAN. *J. Am. Med. Assoc.* 86, 177-8(1926).—The existence in certain bacterial stock cultures of 2 types of cells, characterized, resp., by the formation on agar plates of "rough" (R) and "smooth" (S) colonies, has been demonstrated for a no. of bacterial groups. Under

ordinary conditions, transfers from the *R* and *S* colonies breed true. The importance of the 2 types of colony formation is shown by the correlation of characters: subcultures from *S* colonies form stable suspensions in salt soln., while the cells from *R* colonies tend to agglutinate spontaneously. The acid agglutination optimum is higher for the *S* than for the *R* type; the *S* type is more virulent than the *R*, and there are significant serologic differences. Single cell strains of paratyphoid bacilli of the *R* and *S* type can more or less regularly be made to yield cells of the opposite type by appropriate treatment. A nonvirulent strain can at will be converted into a virulent, and the virulent strain so produced possesses certain correlated characters, such as agglutinability and colony type formation, which distinguish it from the parent type.

L. W. RIGGS

Bacteria in muscular tissues and blood of apparently normal animals. A preliminary report. A. F. REITH. *J. Am. Med. Assoc.* **96**, 325-6(1926).—Cultures of muscular tissues of slaughtered hogs showed the presence of bacteria in 77% of 216 samples examd.; 57% of the samples contained anaerobes. Cultures of the muscular tissues of healthy live hogs, rabbits and guinea pigs show the presence of bacteria in 83% of 108 samples examd.; 49% of these samples contained anaerobes. In the blood of these animals the figures were 67% in 18 samples, and 44% of these samples contained anaerobes.

L. W. RIGGS

Does bacteriophage respire? J. BRONFENBRENNER. *Science* **63**, 51-2(1926). A large no. of expts. with different types of bacteriophage were made in a specially constructed respirometer, and in no case was there any indication of the production of CO₂ or of other phenomena to indicate respiration.

L. W. RIGGS

The use of quinic acid in the differentiation of the colon-aerogenes groups (BUTCHER: 14.

D-BOTANY

B. M. DUGGAR

Dynamics of assimilation of potassium [by plants] from mineral silicates. J. M. DOBRESCU-CLUY. *Chem. Erde* **2**, 83-102(1925).—Applying the methods and formulae worked out by Mitscherlich to studies of the relative availability to plants of the K in various mineral silicates, it was found that the use of water satd. with CO₂ as a solvent gave figures which were in direct disagreement with the results of pot expts. with the same minerals. When, however, dil. HCl was used as the solvent the figures obtained agreed well with the vegetation expts. The 4 minerals—biotite, phonolith, muscovite and orthoclase—are in the order named in regard both to the soly. of the K present in HCl and to its availability to plants, the difference in these respects between biotite and orthoclase being very marked. The more weathered the mineral the greater is the facility with which the K can be assimilated. Water, satd. with CO₂, is very suitable for work on the availability of phosphoric acid but is not equally applicable to the study of other plant nutrients.

B. C. A.

Activity of the proteolytic and related enzymes of certain Hymenomycetae, in the association known as Mycorrhiza. E. MELIN AND K. HELLEBERG. *Biochem. Z.* **157**, 146-55(1925).—The activity of these enzymes has been studied in view of the likelihood that certain mycorrhiza which are associated with the roots of the larch, the pine and the birch render more readily available for the tree some of the N of the humus. The proteolytic activity of an ext. of the young fructifications of these fungi and also the activity of their deaminase vary very much from 1 species to another. A nuclease is present in small quantities in all the species examd. In virtue of these enzymes the mycorrhiza probably assist the tree by providing simpler nitrogenous food material for it from the more complicated compds. of the humus.

B. C. A.

Penetration into Valonia of oxidation-reduction indicators; estimation of the reduction-potential of the sap. MATILDA M. BROOKS. *Proc. Soc. Exptl. Biol. Med.* **23**, 265-6(1926).—The penetration of 3',5'-dibromindophenol into the sap of *Valonia* follows the course of a bimolecular reaction curve and the amt. of dye in the sap at equil. is proportional to the amt. of undissocd. dye in the external soln. At higher temps. and lower concns., the curves are similar in shape to those for two consecutive unimolecular reactions. The dye is found in the sap only in a reduced form. Methylene blue, however, is found in the sap only in an oxidized form; the amt. found in the sap was const. at all external and internal changes in p_H from 5 to 9, at which

p_H values methylene blue is completely dissoed. Other indigo dyes are discussed. The electrode potential of protoplasm was tentatively found. The r_H of the sap was found to be between 16 and 18.

M. M. B.

A study of wheat oil. C. D. BALL. *Cereal Chemistry* 3, 19-39(1926).—Chem. and phys. const. were obtained on oils extd. from wheat embryo and wheat patent flour by ether extn. and also some const. on that obtained from wheat embryo by pressure. Wheat embryo oil differs from wheat flour oil in that it has a higher sapon. no., a higher I no., contains more unsaponifiable matter, and has a lower sp. gr. Embryo oil extd. by pressure has a slightly higher I no. than that extd. by ether. A material seps. out from the flour oil which is not found in the embryo oil. It contains no N, S, or halogens. It m. 96-97°. It gives some of the sterol reactions but is not an alc. In prolonged sapon. it yields a substance with the same m. p. as sitosterol and also gives all the sterol color reactions. It is probably a sitosterol ester. R. B.

The chemical composition of the separative membranes of lemons. ANTONINO FICHERA. *Ann. chim. applicata* 15, 568-72(1925).—Ripe lemons (*Citrus limonum*) were quartered and both the external and the internal fibrous membranes removed and thoroughly washed and dried. The 2 products were then each treated in 2 ways: (1) with HNO_3 (d. 1.15) and (2) with boiling 4% H_2SO_4 . *External membrane.* The dry wt. was 27% of the fresh membrane. On treatment with HNO_3 it yielded mucic acid (corresponding to 1.5% by wt. of galactose in the fresh membrane). Hydrolyzed with boiling H_2SO_4 it yielded galactose (1.37% by wt. of the fresh membrane), glucose and traces of rhamnose. A non-hydrolyzed residue remained (40% by wt. of the dried or 10% of the fresh membrane). *Internal membrane.* The dry wt. was 20% of the original. Oxidation with HNO_3 gave no mucic acid, indicating the absence of galactose, but hydrolysis yielded glucose (4% by wt. of the fresh membranes). No crystallizable sugar could be recovered. The results show that the membranes are composed of complex polysaccharides, including cellulose (the portion not hydrolyzed by hot dil. mineral acids) and hemicellulose (the portion yielding monosaccharides on hydrolysis). The external membranes are composed of cellulose, galactosan and glucosan, the internal vesicular membranes of cellulose and glucosan. C. C. DAVIS

Röntgen-spectrographic comparison of lichenin and cellulose. R. O. HERZOG. *Z. physiol. Chem.* 152, 119-24(1926).—The Röntgen diagrams of β -cellulose (cellulose hydrate) and lichenin are very similar, but by no means identical. This applies especially to the intensities of the interferences. It may be assumed that lichenin and β -cellulose are chem. related, but probably not individual substances, and that the main cryst. component may be identical in both preps. The progressive alteration of the cellulose lattice with repeated reppn. of the substance would indicate that native cellulose is not a primary but a secondary product of the organism. In the reppn. the particles become smaller, and, to a certain extent, amorphous. When moistened, the crystallites give off smaller particles and residual affinities result which take up H_2O . When the H_2O evaps., these affinities cause an aggregation which may not be resolved again by H_2O , so that only the larger gaps take up H_2O adsorptively. The velocity with which the particles arrange into a lattice then becomes zero. The primary particles give rise to amorphous secondary particles. A. W. DOX

Hydration of mosses with water vapor. A. MAYER AND I. PLANTEFOL. *Ann. physiol. physico-chim. biol.* 1, 64-84(1925); *Physiol. Abstracts* 10, 142. —When a living cell is placed in water, exchange is complicated by the passage of other substances than water. By using mosses in vapors of which the tension can be measured, information of a new order is obtained showing variable affinity according to previous content in water temp., etc. H. G.

Some protein properties of plant protoplasm. W. H. PEARSALL AND J. EWING. *Brit. J. Exptl. Biol.* 2, 347-56(1925); *Physiol. Abstracts* 10, 252. —There is a general tendency for the proteins of the higher plant to be isoelec. at about p_H 4.0 to 4.5. Aggregation and pptn. of the particles of the protoplasm of wheat take place at about p_H 4.1. Typical uniform tissues like potato tubers and bean cotyledons stain more strongly with basic dyes between p_H 5 and 7, and with acid dyes at p_H 3 to 4. In acid solns. a marked depression in the swelling curve for potato occurs at about p_H 4.5. Heat coagulation of *Spirogyra* is effected more easily in presence of dil. acids than in pure water or in presence of alkalis, while in potato and beetroot heat coagulation is produced most rapidly at p_H 4.4. Plant protoplasm thus shows properties that are also those of the proteins extd. from the tissues. H. G.

Variations in the permeability of leaf cells. H. H. DIXON. *Sci. Proc. Roy. Dublin Soc.* 17, 349-56(1924); *Physiol. Abstracts* 10, 253. —The elec. resistance of the leaf was measured in *Syringa vulgaris* and *Hedera helix*. The resistance falls considerably

as temp. increases from 0° to 50°. The av. temp. coeff. was 1.334. The resistance of the leaf appears to increase with age, probably on account of the increase in the intercellular space system. The living leaf possessed a resistance 6 to 22 times that of the leaf killed by exposure to CHCl_3 or CS_2 . H. G.

Influence of light on the absorption of nutrients by young [rye] plants. H. WIESSMANN. *Z. Pflanzenernähr. Düngung* **B4**, 153-5(1925).—Three lots of plants were grown in sand, treated with a complete fertilizer, and exposed to light in the open, light from a northern window, and light from a southern window, resp. The dry weights of green matter and roots and the total potash and P_2O_5 contents were all considerably higher for the plants exposed to the southern light than for those exposed to the northern light. The plants grown in the open had higher values for all detns. than had either of the other 2. H. G.

The role of the chloroplasts in protein formation in green plants. [HERMANN ULLRICH. *Z. Botanik* **16**, 513-62(1924); *Ber. ges. Physiol. expll. Pharmacol.* **29**, 229(1925)]. The size of the chloroplasts increases with N supply and protein formation and is reduced by N hunger and by digestion of the proteins with pepsin-HCl. Parallel to the protein decrease is a change of the color to yellow. Regeneration by N supply is possible only when the protein loss does not exceed a certain value. MARY JACOBSEN

The action of stimulants on the growth of plants. H. BEHN. *Angew. Botanik* **6**, 201-24(1924); *Ber. ges. Physiol. expll. Pharmacol.* **29**, 233(1925).—Trypaflavine, 3,6-diaminoacridine nitrate and sulfate, MgSO_4 - MnSO_4 , NH_4NO_3 -K phosphates and a no. of stimulants of unknown compn. were studied. The effect on growth was but slight and depended on the nature of both plant and soil. MARY JACOBSEN

The formation of resins in conifers. I. The formation of resin in *Pinus cembra*. GH. V. PIGHULEVSKII AND V. V. VLADIMIROVA. *J. Russ. Phys. Chem. Soc.* **56**, 325-34(1925); cf. *C. A.* **19**, 2222.—The needles of *Pinus cembra* contain 10% resin. The accumulation of resins begins when the buds open and continues during the development of the needle. The periods of max. production of dry matter and resin are coincident. The formation of essential oils lags behind that of resin and reaches its max. only after the accumulation of dry matter has ceased. The resin content increases in the 2nd and 3rd years at the expense of the high-boiling constituents of the essential oils. Complicated ethers and acids are among the constituents of the resin. The acid content is lower in the early stage of the development than in the somewhat older needles and decreases again in the 1st and 2nd years. II. **Study of the formation of resin in *Pinus cembra*.** GH. V. PIGHULEVSKII. *Ibid* 335-48.—During severe frosts resinous secretion is forced out of cut twig ends owing to the compression of the resin ducts by cold. The essential oil content of this secretion was 33%. Once secreted the resin is not regenerated during the following period of growth. III. **The formation of resin in *Abies sibirica*.** GH. V. PIGHULEVSKII AND V. F. GRIGORIEVA. *Ibid* 349-58, cf. *C. A.* **19**, 2223.—*Abies sibirica* contains 14% resin. The time of its formation in relation to growth and to other constituents is discussed. The compn. in the various periods of vegetation is similar to that of *Pinus cembra*. The essential oil content of the secretion is 27.6%. IV. **The formation and transformation of the essential oil in *Pinus strobus*.** GH. V. PIGHULEVSKII AND V. V. VLADIMIROVA. *Ibid* 359-66.—The essential oil content of *Pinus strobus* is 1% of the dry matter. Essential oil is formed during the entire period of growth and reaches its max. after the accumulation of dry matter has ceased. Gradually the high-boiling constituents of the essential oil disappear, possibly to form resin as in *Pinus cembra*. The resin, amounting to 6%, contains acids and complicated ethers. The essential oil content of the secretion is 15.9%. MARY JACOBSEN

The action of dressings pathological to plants. HENRIK LUNDEGARDH. *Bot. Zentr.* **44**, 465-87(1924).—The absorption of Cu ions by wheat is localized chiefly in the outer coverings to which the pathogens adhere. This reaction occurs periodically and recalls the Liesegang phenomenon. The Cu absorption is influenced by salts in proportion to the lyotropic properties. The "germination-energy" of the seeds varies periodically with the increase in the amt. of absorbed Cu ions. Very small amts. inhibit, larger amts. do not interfere, still larger amts. inhibit again, etc. Treatment of the seeds with 0.01 N HgCl_2 calls forth similar periodical response. The action of various concns. (0.000001 to 0.001 N) for a definite period gives results similar to those obtained when the concn. is kept const. and the time interval varied. F. K.

The period of maximum oxygen intake. M. G. STRÅLFELT. *Biol. Zentr.* **46**, 1-11(1926).—The period of max. O_2 intake by young plants (*Sinapis alba*) is established. In the germinal layers there is a very sharply marked period of max. O_2 intake—the highest point being reached the 4th day of germination. During the growth of the root

and the stem the intake of O_2 decreases rapidly. The maxima for different parts of the plant are different and the duration of these maxima varies. In general, the O_2 intake for the germinating portion is many times that used by the root and stem together.

FRANCES KRASNOW

The permeability to oxygen of the wounded and intact embryo of *Sinapis alba*. M. G. STÄLFELT. *Biol. Zentr.* 46, 11-23(1926).—The O_2 which germinating seeds of *Sinapis alba* take from the air is significantly lower than the amt. they can convert. With an increase in the partial O_2 pressure of 20 to 50%, the O_2 intake increases. The intake is greater for the germ than for the root as long as the germ is enclosed by the seed covering. If the root is cut close to the germ, the O_2 intake decreases; this may mean that the O_2 permeability was decreased. The decrease may be overcome by an increase in the partial pressure or removal of the seed shell. At a pressure of 0.2 atmosphere, the O_2 intake of the root is not interfered with after one or two cross-section cuts. A decrease in permeability does not hinder the diffusion of O_2 . Interference sets in only after abundant destruction.

FRANCES KRASNOW

The rate of reproduction of *Lemna major* as a function of intensity and duration of light. N. A. CLARK. *J. Phys. Chem.* 29, 935-41(1925).—The rate of reproduction of *Lemna major* under elec. light from Mazda lamps with av. intensities of 400 and 900 foot candles at the surface of the solns. increased with increased length of day up to continuous light. Plants under 900 foot candles at all lengths of day reproduced more rapidly than those under 400 foot candles. With continuous light of 900 foot candles and a 12-hr. change of soln. the rate of reproduction was increased and the health of the plants maintained. It is possible that the failure of some investigators to get reproduction with certain plants under 24 hrs. light may be due to the fact that the environment of the plant, with regard to food, reaction, etc., is not suited to the rapid growth attained with continuous illumination.

H. R. KRAYBILL

Review of the relationship between parasitic plants and the respective host. A. ZIMMERMANN. *Centr. Bakt. Parasitenk., II Abt.* 65, 311-8(1925).—There is a mass of botanical data. Also some chem. data are given concerning the effect of antiseptics on germination.

JOHN T. MYERS

Occurrence and disappearance of starch in lichens. FR. TOBLER. *Ber. botan. Ges.* 41, 406-9(1923).—Starch is present in numerous species of lichens exterior to the walls of the algae, in greatest amounts in autumn and least in spring. The hyphae of the fungus excrete an enzyme capable of hydrolyzing this starch and "in vitro" rice starch. The starch exterior to the algae is the first to disappear when the lichens are placed in the dark.

W. NEWTON

Metachromatic staining of plant cell walls with substantive dyes. I. II. FRANK SCHWARZ. *Ber. botan. Ges.* 42, 21-8, 28-38(1924).—Staining with substantive dyes is recommended because the dispersion varies with the nature of the tissue and consequently the same dye gives distinct colors with each specific tissue. The color differentiation is more marked in the cell wall than in other plant tissues. Color reactions of individual dyes upon different types of cell wall tissue are described, and dye groups are arranged according to their value in the differentiation of specific tissue. A description is given of the staining technic for this class of dyes.

W. NEWTON

Silicon metabolism of diatoms. F. BRIEGER. *Ber. botan. Ges.* 42, 347-55(1924).—In the nutrition of diatoms an optimum concn. of $K_2Si_2O_5$ between 0.031 and 0.063% is found for *Fragilaria*, *Navicula* and *Nitzschia*. There is a distinct optimum for each species. The harmful effects of higher concn. are due to the OH ion. Sol. silicates appear to be necessary, for only one species decomposed SiO_2 . Absorbed Si is deposited in the shell as an org. complex. The mature shell can be neither distended nor dissolved by the diatoms.

W. NEWTON

Depletion of the endosperm in *Zea* mais. FRIEDA BESSENICH. *Jahrb. wiss. Botanik* 63, 231-72(1924).—Conversion of starch to dextrose is observed in excised endosperms in the presence of water. The rate is decreased by the addn. of $CaSO_4$.

$PO_4 + Na_2HPO_4$ buffers at pH 5 slightly accelerate the rate of depletion, but at pH 0-4 marked inhibition obtains. The inhibition through the addn. of NaOH increases with the OH-ion concn.

W. NEWTON

Effect of salts on the depletion of the endosperm in *Zea* mais. PAUL DAHM. *Jahrb. wiss. Botanik* 63, 273-320(1924).—Starch hydrolysis is depressed by chlorides in the order, $Na, NH_4, Mg, Ca, Sr < K < Ba < Li$ and by sodium salts in the order, $SO_4, NO_3, Cl, H_2PO_4 < SCN, C_2H_3O_4 < Br < B_4O_7 < CO_3, HPO_4, OAC$. The optimum rate of hydrolysis takes place at pH 6 under low saline conditions. Diastase is generated

in the aleurone but not in the inner endosperm or scutellum. The activity of the diastase within the cells is not affected by the same factors as those which affect the enzyme diffusing out.

W. NEWTON

The effect of the hydrogen-ion concentration on the availability of iron for *Chlorella* sp. E. F. HOPKINS AND F. B. WANN. *J. Gen. Physiol.* 9, 205-10(1925).—Unless precautions are taken to keep the Fe sol in the culture soln., the results obtained by varying the H-ion concn. will not represent the effect of H ion upon growth. Fe is pptd. at the lower H-ion concns., and Fe in some salts more readily than in others. Fe citrate is the most favorable source of Fe for plant culture media. Fe may be removed from culture solns. by adsorption on amorphous ppts. like Ca phosphate. By omitting Ca, Fe may be kept in soln. at alk. reactions by adding Na citrate. When working with varying H-ion concns. in these media strongly buffered solns. should be used.

C. H. R.

X-ray diffraction patterns from plant tissues. O. L. SPONSLER. *J. Gen. Physiol.* 9, 221-33; *Science* 62, 547-8(1925).—The structural units in the wall of the fiber form a space lattice, the elementary cell of which is an orthorhombic structure. The units are probably composed of a group of atoms more or less closely packed together.

C. H. R.

Accumulation of brilliant cresyl blue in the sap of living cells of *Nitella* in the presence of ammonia. M. IRWIN. *J. Gen. Physiol.* 9, 235-53(1925); cf. C. A. 20, 221.—"When the living cells of *Nitella* are placed in a soln. of brilliant cresyl blue contg. NH_4Cl , the rate of accumulation of the dye in the sap is found to be lower than when the cells are placed in a soln. of the dye contg. no NH_4Cl and this may occur without any increase in the pH value of the cell sap. This decrease is found to be primarily due to the presence of NH_3 in the sap and seems not to exist where NH_3 is present only in the external soln. at the concn. used."

C. H. R.

The penetration of carbon dioxide into living protoplasm. W. J. V. OSTERHOUT AND M. J. DORCAS. *J. Gen. Physiol.* 9, 255-67(1925).—Little or no CO_2 enters normal cells of *Valonia macrophysa* except as undissocd. mols. When the interior of the cell is more acid than the surrounding medium, the internal concn. of total CO_2 at equil is less than the external. Methods are given.

C. H. R.

Suspension of the life of seeds in a vacuum at a temperature of liquid helium. PAUL BECQUEREL. *Compt. rend.* 181, 805-7(1925); cf. C. A. 3, 1761.—Seeds of rampion, tobacco, clover, amaranth, toadflax, rocket, snap-dragon and eschscholtzia were desiccated in a vacuum at 40° and were divided into 3 series for germination tests as follows: (1) Control, in which the seeds after desiccation were kept in the dark. (2) The seeds were kept in a vacuum for 4 months after desiccation. (3) The sealed tubes contg. the seeds in a vacuum were immersed in liquid He at -269.2° for 10.5 hrs. The 3 series of seeds were then allowed to germinate at 28° , when it was found that neither deprivation of air nor exposure to a temp. of -269.2° for 10.5 hrs. lessened the germinating vitality of the seeds.

L. W. RIGGS

Localization of bromine in a floridian alga (*Antithamnionella sarniensis* Lyle). C. SAUVAGEAU. *Compt. rend.* 181, 841-3(1925).—Cells of the plant when placed in ammoniacal fluorescein indicate the presence of Br, either free or in very loose combination.

L. W. RIGGS

Bromides of the *Antithamnion* Naeg. C. SAUVAGEAU. *Compt. rend.* 181, 1041-3(1925); cf. preceding abstr.—Br was found in dried specimens of various species of *Antithamnion* which had been preserved for more than 20 years. These specimens were collected in different European countries and in America.

L. W. RIGGS

The enzymes produced from the seeds of various species of *Rhamnus*, or "Rhamnodiaestase." M. BRIDEL AND C. CHARAUX. *Compt. rend.* 181, 925-6(1925).—Fresh seeds of *Rhamnus utilis* Dene are ground and sifted to remove the outer inactive portions and the meal is extd. with Et_2O to remove the fat. The meal is then allowed to macerate in 3 times its wt. of distd. water contg. some thymol. After expression the clear liquid is treated with 4 vols. of 95% alc. and the resulting ppt. is washed and dried. Yield 6.8%. By a more thorough procedure the yield may be raised to 10.7%. The rhamnodiaestase thus prepd. is a source of several enzymes which show particular behavior with certain glucosides (cf. following abstract). Also in *Bull. soc. chim. biol.* 8, 35-9(1926).

L. W. RIGGS

Methods of biochemical study in plants of the glucosides hydrolyzable by "rhamnodiaestase." M. BRIDEL AND C. CHARAUX. *Compt. rend.* 181, 1167-8(1925); cf. C. A. 19, 2108; 20, 220 and preceding abstract.—Rhamnodiaestase hydrolyzes only partially various glucosides, that is, the resulting mols. of glucose remain combined as glucidic complexes, rutinose, primeverose, rhaminose, etc. The action of rhamnodiaestase is

less sp. than that of emulsin. The biochem. method with rhamnodistase as with emulsin should be a point of departure for work upon glucosides as yet unknown. Rhamnodistase may be utilized in plant physiology, to det. the variations in the glucosidic content of plants during their growth. Also in *Bull. soc. chim. biol.* **8**, 40-9 (1926).

L. W. RIGGS

Equilibrium of cellular constituents and intensity of oxidations in the cell. Imbibition and oxidations. Case of seeds. RAYMOND JACQUOT AND ANDRÉ MAYER. *Compt. rend.* **181**, 931-3 (1925).—Seeds of bean, corn and peanut were subjected to conditions of varying humidity and the CO_2 evolved per hr. under the different conditions was measured. Increased imbibition of water by the seed results in increased oxidation up to a limit of imbibition which differed with the species. Beyond this limit additional imbibition of water is accompanied by a sharp fall in the oxidation.

L. W. RIGGS

Influence of the electrolytes in the medium upon the gaseous exchange of mosses. ANDRÉ MAYER AND L. PLANTEFOL. *Compt. rend.* **181**, 1094-5 (1925); cf. *C. A.* **18**, 2361.—Mosses were immersed in solns. of NaCl , NaNO_3 , Na_2SO_4 , Na_2SiO_3 , Na_2PO_4 and NaAcO , resp. in mixts. of NaCl , KCl and CaCl_2 , and in mixts of Na_2SO_4 , $\text{Al}_2(\text{SO}_4)_3$ and $\text{La}_2(\text{SO}_4)_3$ in concns. ranging from 0.001 N to N ; also in acetic, butyric, citric and picric acids in concns. ranging from 0.00005 N to 0.1 N . The O consumed and the CO_2 evolved were measured. The results show that the concn. of the medium in electrolytes has a very definite action upon the nature and intensity of the respiratory exchanges of mosses. The variations produced by different salts at various concns. are too many to be formulated in a general statement.

L. W. RIGGS

Variations of the p_H in certain Sphagnum peat bogs in central and western France. P. ALLORGE. *Compt. rend.* **181**, 1154-6 (1925).—Two types of vegetation are recognized according to elevation and are illustrated by that of the Margeride mountains with an altitude of 1400 m. (arctic type) and the Atlantic type in the Maine province, altitude 545 m. The flora of the bogs studied is cataloged, and the p_H of the peat varies somewhat according to the character of the vegetation covering the bog. *Sphagnum* bogs have an acidity ranging from p_H 3.9 to 4.6. In other bogs the range is 4 to 6.8.

L. W. RIGGS

Chemical characters of green, yellow and red leaves. H. COLIN AND A. GRANDSIRE. *Compt. rend.* **181**, 1168-70 (1925).—The reducing sugars, sucrose, water, ash, alkyl. of ash, Ca content, lowering of f. p. and elec. cond. were detd. The last two detns. were made on 3 g. of fresh leaves finely ground and suspended in 25 cc. of water. Compared with normal green leaves, red leaves of autumn are richer in sugars and free organic acids, but not in acid salts. Red leaves are less mineralized and are partially decalcified. Yellow leaves are poor in sugar but rich in minerals.

L. W. RIGGS

Influence of light on the formation of tannins. MICHEL-DURAND. *Compt. rend.* **181**, 1171-3 (1925); cf. *C. A.* **18**, 1516; **19**, 1585.—Young plants of oak and chestnut were grown in light and in darkness and the tannins of the entire plants, roots, stems and leaves were detd. by extn. with acetone and with water. Plants grown in darkness from seeds contg. only traces of tannin in their cotyledons actively elaborate the tannins in all of their parts. The tannin content may represent 14% of the wt. of the stems and 23% of the leaves. It is necessary that the plants have at their disposal abundant nutritive reserves. In general plants in darkness produce less tannin than those in light. This action of light is particularly strong in its effect upon the tannin content of the roots. In darkness the tannins tend to accumulate in the stems and leaves. These conclusions are verified with seeds the cotyledons of which contain much tannin.

L. W. RIGGS

Age of seedlings as a factor in the resistance of maize to sodium chloride. G. J. HARRISON AND C. J. KING. *J. Agr. Research* **31**, 633-40 (1925).—Corn seedlings in water cultures show extreme variation of tolerance to NaCl depending on the size. Young seedlings with short radicles and undeveloped plumules are most susceptible to NaCl , older plants with 2 seed leaves follow next in susceptibility and the intermediate stages are the most resistant. Artificial excision of the radicles increases the resistance of the seedlings to a marked degree causing a prompt and comparatively rapid development of permanent roots and plumule even while exposed to a strong salt soln. The resistance of seedlings are apparently influenced greatly by changes in weather conditions and it was therefore not found possible to obtain consistent results when comparing behavior of seedlings subjected to salt solns. on different dates.

W. H. ROSS

Sulfate content of the leaf-tissue fluids of Egyptian and Upland cotton. J. A. HARRIS, CLARA T. HOFFMAN AND W. F. HOFFMAN. *J. Agr. Research* **31**, 653-61 (1925);

cf. *C. A.* 18, 2022.—The sulfate content of the leaf-tissue fluids of Meade and Lone Star Upland cotton is higher than in that of Pima Egyptian cotton. The differences range from 3 to 4 g. per l. of leaf-tissue fluids, or from 18 to 28% of the sulfate in the fluids of the Upland variety. These results as compared with those of the earlier study (*C. A.* 19, 844) of chloride content show that, as far as the varieties investigated are concerned, the behavior of these 2 types of cotton with respect to the absorption of chlorides and sulfates is quite different, the Egyptian type taking up larger quantities of chlorides and the Upland types absorbing larger quantities of sulfates. W. H. R.

The transport of sugar by plants. ADOLF MAYER. *Landw. Vers. Sta.* 104, 103-8 (1925).—A discussion. F. M. SCHERTZ

Leaf cytoplasmic proteins. A. C. CHIBNALL. *J. Am. Chem. Soc.* 48, 728-32 (1926).—An examn. of the physicochem. properties of cytoplasm may help to explain the mechanism of cell permeability. The analysis of spinach leaf cytoplasm gave. EtOH-sol., 12.7; ash, 15.1; protein, 64.6%; amide N (% of "free" protein), 6.93; humin N in acid, 0.76; humin N in lime, 1.46; humin N in C_2H_5OH , 0.25; cystine, 1.27; arginine, 13.80; histidine, 3.89; lysine, 9.63; amino N in filtrate, 58.09; non-amino N in filtrate, 2.58. The isoelec. point of the cytoplasmic proteins and the H-ion concn of the contents of the leaf cells were, resp., spinach, 5.0-4.0, 6.57; hogweed 5.0-4.3, 6.19; broad bean, 5.1-4.3, 5.69; cabbage, 4.7-4.0, 5.60; rhubarb, 3.5, 4.00; *Vitis vinifera*, 4.8-4.4, 3.02. C. J. WEST

The N and mineral requirements of the plantain (NORRIS, AYYAR) 15.

E—NUTRITION

PHILIP B. HAWK

Effect of ultra-violet light on protein metabolism. S. YOSHINE. *Strahlenther.* 18, 201-11(1924).—The positive N balance of irradiated dogs showed a slight rise when the exposure was short, changing to a negative balance on longer exposure. With increase in the positive balance, the excretion of amino acids in the urine diminished somewhat. Longer periods of irradiation led to disturbance in the assimilation of nitrogenous substances in the intestine and to refusal of food. B. C. A.

Sex differences in the requirements of certain food factors. G. A. HARTWELL. *Brit. J. Exptl. Biol.* 2, 323-30(1925); *Physiol. Abstracts* 10, 224.—From the fact that on specified diets the male rat grows at about the same rate as the female and does not exhibit the more rapid growth characteristic of the male of the species it is inferred that the growing male requires relatively more vitamin B, and is also more susceptible to the quality of the protein components of its food. H. G.

The isolation of vitamin B. SOGEN TSUKIE. *Jikken Ig. Z., Tokyo* 5, 539-74 (1922); *Japn. J. Med. Sci.* 2, 13.—Treat the alc. ext. of rice bran with ether to ext. fatty substances and then with phosphotungstic acid. Sep. the ppt. formed and decompose with BaO. Filter off the Ba phosphotungstate. To the filtrate, after it is acidified with HNO_3 , add $AgNO_3$. Here hypoxanthine and xanthine appear. Filter. On neutralizing the filtrate with BaO a ppt. is produced. Dissolve this again with HNO_3 - $AgNO_3$ soln. and ppt. with NH_4 - $AgNO_3$ soln. Treat this ppt. with alc. and then with ether, and pulverize. The yield is 0.3-0.5 g. from 4 kg. of rice bran. 0.005-0.05 g. of this substance is able to prevent the outbreak of neuritis of fowls fed exclusively with polished rice. H. G.

The acidity of the blood serum of fowls suffering from polished-rice disease. RYUICHI AKIBA. *Keio Ig. Tokyo* 2, 142-8(1922); *Japn. J. Med. Sci.* 2, 15.—Fowls suffering from polished rice disease showed an increase of acidity and accordingly a decrease of acid-neutralizing capacity of the blood serum, when the several symptoms became manifest. These changes in the blood serum, however, disappeared, when the fowls recovered after they had been fed with ext. of rice bran. H. G.

The occurrence and significance of the vitamin A group. GEORG VON WENDEL. *Klin. Wochschr.* 4, 2389-90(1925).—The vitamin A content of food diminishes during the winter months. Vitamin A is slowly oxidized when foods are stored. Cattle fodder, such as hay and carrots, becomes markedly deficient as sources of A as the winter progresses; hence milk and the other dairy products also are deficient in A. This vitamin deficiency of winter foods leads to a decreased rate of growth in children during the winter months. Statistical figures are given. MILTON HANKE

The relation between scurvy and tuberculosis in guinea pigs. BRUNO HEYMANN. *Klin. Wochschr.* 5, 59-62(1926).—Tuberculous guinea pigs, fed on a vitamin-C-deficient diet, die much sooner than those fed on a normal diet. MILTON HANKE

The influence of avitaminosis on the healing of bone fractures. ARTHUR ISRAEL AND ROBERT FRANKEL. *Klin. Wochschr.* 5, 94-7(1926).—A broken femur, in a properly nourished guinea pig, shows a rounding of the broken edges in 8 days, periosteal callus in 14 days and complete consolidation in 5-6 weeks. The broken femur shows no signs of repair in 3-4 weeks in an animal that is kept on a diet free from vitamin C. Normal repair can be started at any time by adding vitamin C to the diet. A condition resembling pseudoarthrosis in man can be developed in guinea pigs, with broken femurs, that are kept in a state of chronic scurvy by feeding small amts. of lemon juice as the only source of vitamin C. The fracture becomes covered with a loose callus; but the broken bones are not cemented together. A series of animals, with broken femurs, were allowed to repair on a normal diet for 14 days. Vitamin C was then removed from the diet. The repair process proceeded normally for 4 weeks. At this time the animals were at the point of death from scurvy. They were revived by feeding small amts. of carrots. The animals were then kept in a chronic scurvy state. The newly formed callus gradually atrophies and becomes decalcified until it consists of an easily broken shell.

MILTON HANKE

New observations on fat-soluble growth factors. H. V. EULER. *Arkiv. Kemi. Mineral. Geol.* 9, No. 28, 6 pp. (1925); cf. *C. A.* 19, 3104; 20, 222.—The growth-promoting power of irradiated solns. of cholesterol in ivory-nut oil was not proportional to the cholesterol content. Irradiated solns. of cholesterol acetate in peanut oil showed no growth-promoting or antirachitic power; negative results were also obtained with cholesterol palmitate. In expts. on irradiated sitosterol and benzene exts. of wheat embryo and of yeast the growth-promoting power was proportional to the sterol content, but the antirachitic power was not parallel, being remarkably high in the exts. Irradiated β -amyrin and betulin were inactive as growth-promoters; betulin showed antirachitic action.

WILLIAM J. HUSA

Butter, fresh beef and yeast as pellagra preventives, with consideration of the relation of factor P-P of pellagra (and black-tongue of dogs) to vitamin B. JOSEPH GOLDBERGER, G. A. WHEELER, R. D. LILLIE AND L. M. ROGERS. *U. S. Pub. Health Repts.* 41, 297-318(1926); cf. *C. A.* 19, 2693, 3118.—Black-tongue of dogs is analogous to pellagra in man; both diseases are interpreted as due to deficiency of a pellagra-preventive factor (factor P-P). Butter is poor in factor P-P. A daily allowance of 200 g. of lean beef, or 15 g. of a com. dried aq. ext. of yeast, in the diet of adult persons, is adequate for prevention of pellagra, but not fully adequate for prevention of beriberi. Factor P-P is distinct from the antineuritic factor of water-sol. B, but may be identical with the growth-promoting factor; this means that it may possibly be identical with Wildiers' bios. The factor P-P is thermostable. From the evidence presented, it is pointed out that the so-called growth-promoting factor of water-sol. B may be inactive by itself, and active only in combination with the antineuritic factor.

W. J. H.

Renal injuries by amino acids. L. H. NEWBURGH AND P. L. MARSH. *Arch. Internal Med.* 36, 682-711(1925); cf. *C. A.* 18, 2739; 19, 3296.—The investigation was suggested by the renal injuries following high-protein diets. Intravenous injections of amino acids into dogs and rabbits demonstrated the marked toxicity to the kidney of lysine, histidine, tyrosine, tryptophan and cystine. Arginine and aspartic acid are mildly nephrotoxic, while alanine, leucine, glycine, phenylalanine and glutamic acid even in doses of 2 mg. per kg. did not affect the kidney. Cumulative effects from repeated small doses were observed. Cystine also produced toxic effects when introduced through the portal vein of dogs or added to a standard diet of rats.

M. J.

The premortal nitrogen increase and its relation to the thyroid. ALFONS SCHÖN. *Beitr. Physiol.* 3, 165-87(1925).—S. found in contrast to Mansfeld and Hamburger that the premortal N increase in starvation was the same in 2 normal A and 2 thyroidectomized B dogs. The O intake per sq. m. was the same in both A and in one B, while the other B showed an increase of 17%. There was no rise in metabolism. A considerable improvement in the condition of the extremely emaciated animals could be produced by the administration of glucose, citric acid and egg in water.

M. J.

Metabolism on pure carbohydrate and pure meat diet. FRANZ SCHRÖTER. *Beitr. Physiol.* 2, 263-6(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 893(1925).—In three-day expts., the respiratory quotient was detd.

MARY JACOBSEN

The energetic value of woman's milk and the growth of the infant. LUIGI POLLINI. *Osp. magg.* 12, 182-9(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 60.—The caloric value of 1 l. milk is 600-1000. There are considerable individual variations, smaller in healthy women. The value calcd. from analysis is usually lower than that directly detd. for the total milk. Individual constituents show marked variations, e. g., 1 g. fat 8.5-9.9 cal. A low d. is often combined with a high caloric value. The growth

of the infant usually depends on the no. of calories, but good growth was observed with a low cal. no. With equal cal. nos. milk of a higher concn. gives better results.

Changes in the hypophysis in chronic hunger. S. K. SEDLEZKY. *Z. Konstitutionslehre* 10, 356-66(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 769(1925).—In persons of any age who died from starvation the hypophysis shows a slight decrease in weight, an increase in secretion and change of secretion (basophilia). Basophilic cells and granula are prevalent.

Metabolism of cold-blooded animals. I. KAI HSÜ. *Z. Biol.* 83, 45-52(1925).—It is shown that frogs can be kept in N equil. for a short time only. The meal worms constituting the diet are incompletely digested.

Formation of vitamin A during the germination of seeds. WILHELM STEPP. *Z. Biol.* 83, 94-8(1925).—The vitamin A produced during germination of wheat is sufficient to prevent keratomalacia but not to increase the wt. of the animal.

The effect of changes in regime upon the urinary alkaline tides in a normal individual. M. MUSCHIAT. *J. Clin. Invest.* 2, 245-53(1926).—The pH of the urine was detd. every 2 hrs. during the day for 27 days, on 20 of which the subject had 2 meals a day (morning and evening), on 3, only one meal (at 1 p. m.), on 3, three meals, on 1 day breakfast, followed by rest in bed until noon. Under all these conditions 2 alk. tides were observed, one at a max. about noon, and the second about 8 p. m.

The vitamin content of foodstuffs. W. H. EDDY. *Am. J. Pub. Health* 16, 109-15(1926).—The importance of standardized diets in expts. designed to test comparative vitamin content of food is emphasized. In the case of foods low in certain vitamins, the possibility arises that the large consumption of the food tested may reduce the consumption of the basal diet, so as to introduce other dietary deficiencies. By the use of Sherman's standard diets and methods, the minimum protective dose against scurvy per guinea pig per day of ripe bananas was 5-8 g. 0.4-0.5 g. bananas furnish sufficient vitamin A to produce an av. gain of 25 g. per rat in 8 weeks, while more than 7 g. of bananas are required to furnish vitamin B for a gain of 20 g. per rat in 8 weeks.

The prevention of rickets. H. C. SHERMAN, E. L. FISK, I. GREENWALD, T. P. B. JONES AND C. E. A. WINSLOW. *Am. J. Pub. Health* 16, 139-41(1926).—Report of the Committee on Nutritional Problems of the Am. Pub. Health Assoc.

Vitamins in canned foods. V. Peaches. E. F. KOHMAN, W. H. EDDY, VICTORIA CARLSSON AND NELLY HALLIDAY. *Ind. Eng. Chem.* 18, 302-4(1926).—The min. protective dose of raw peaches against scurvy was 5 g. daily per guinea pig. The equiv. of 5 g. of raw peaches canned and fed after 6-12 months gave results comparable to 5 g. of raw peaches. In contrast to the canning of apples (*C. A.* 19, 543), the elimination of O from the fruit previous to canning did not favorably influence the vitamin C content of the canned product. Commercially canned peaches contained 4-5 times as much vitamin C as kettle-cooked peaches. On the dry basis, canned peaches were about $\frac{1}{3}$ as potent in their content of vitamin A as butter fat, while the content of vitamin B was so low that the large quantities necessary for protection of rats resulted in disturbances of general nutrition.

The maintenance requirement of cattle for protein as indicated by the fasting catabolism of dry cows. E. B. FORBES, J. A. FRIES AND M. KRISS. *J. Dairy Sci.* 9, 15-27(1926).—Urine and fecal analyses (N, crude fiber and dry matter) are reported for fasts of 3-9 days duration by dry dairy cows. The bulk of the residual feed present in the alimentary canal was eliminated in the first 2 or 3 days of the fast, but the elimination of the same was incomplete even after 9 days of fasting. The av. daily excretions per 1000 lbs. in the last 4 days of the 9-day fast were 46.5 and 43.6 g., resp., for 2 animals, equiv. to 0.62 and 0.58 lb. of body protein. This figure which is considered to represent the protein catabolism of fasting is identical with Armsby's estimation of the digestible crude protein maintenance requirement of cattle.

The role of the antiscorbutic vitamin in the nutrition of calves. L. M. THURSTON, C. H. ECKLES AND L. S. PALMER. *J. Dairy Sci.* 9, 37-49(1926).—Calves do not require vitamin C in quantities which can be measured by the present method of testing food materials for antiscorbutic potency (*i. e.*, development of scurvy in guinea pigs).

A study of calcium and phosphorus balances with dairy cattle. R. C. MILLER. *J. Dairy Sci.* 9, 78-92(1926).—The substitution of clover hay for timothy as part of a ration which included silage and grain mixt. resulted in a slightly improved assimilation of Ca. Some evidence of the independence of Ca and P assimilation was obtained. The assimilation of P was increased when more P was present in the grain mixt.

variation in the Ca and P content of the milk was observed, although the % of P in the milk seemed to increase slightly in response to an increased supply in the feed.

H. B. L.

Observations on vitamin B and metabolism. R. H. A. PLIMMER, J. L. ROSEDALE AND W. H. RAYMOND. *J. State Med.* **34**, 117-21 (1926).—Expts. with pigeons showed that vitamin B must be increased as the total caloric requirements of the bird increased if normal nutrition and rearing of the young are to be obtained. Studies to det. the amt. of various cereals necessary to supplement polished rice or white flour and furnish vitamin B demonstrated the superior value of wheat germ, yeast and yeast ext. The value of bran and middlings was greater than that of flour, due largely to the wheat germ present. Shortage of vitamin B in human dietaries may be associated with the origin of common gastro-intestinal disorders.

H. B. LEWIS

Some nutrition experiments with brewer's yeast, with especial reference to its value in supplementing certain deficiencies in experimental rations. M. I. SMITH AND E. G. HENDRICK. *U. S. Pub. Health Repts.* **41**, 201-7 (1926).—Dried brewer's yeast contains a factor essential in nutrition other than vitamin B. This factor is not present in coagulated yeast protein, is still active after autoclaving at 15 lbs. pressure for 6 hrs., and can adequately supplement a ration in which the oat kernel is the sole source of protein and vitamin B. A synthetic ration with casein as the sole source of protein and contg. Seidell's purified vitamin B picrate must be supplemented with this unrecognized factor present in yeast in order to make it adequate. If properly supplemented, oat protein appears to be as satisfactory in the nutrition of the rat as is casein.

H. B. LEWIS

Vitamin studies. XI. Inorganic blood phosphorus and bone ash in rats fed on normal, rachitic, and irradiated rachitic diets. R. A. DUTCHER, MATTIE CREIGHTON AND H. A. ROTHROCK. *J. Biol. Chem.* **66**, 401-7 (1925).—"In normal rats, weighing between 35 and 40 g., the inorg. P was 10 mg. per 100 cc. of serum and during an 8-week feeding period, the tendency was to maintain this level, falling slowly to 8 mg. at the end of 8 weeks. The % of ash in the dry extd. femurs of the same normal rats was 40 at the beginning of the expt. and increased steadily during the 8-week period, to 62%. When rats received Steenbock's rachitic ration, inorg. blood P dropped from 10 to 1.6 mg. in a period of 3 weeks. After that it rose slowly as the result of fasting. The ash of the femurs of the rachitic rats fell from 40 to 26.5% in 3 weeks and finally fell as low as 24%. When Steenbock's rachitic ration was irradiated with ultra-violet light the inorg. blood P and the % of bone ash fell midway between the normal and rachitic groups. It would appear that the rat does not possess the ability to store the antirachitic factor in significant amts. for the reason that Ca and P deposition is hampered from the very beginning of the exptl. feeding period. The method offers an opportunity to make a quant. study of the antirachitic properties of food materials, by using as a standard the least amt. of any food which will prevent fall in the % of bone ash below that possessed by the young animals at the beginning of the expt. or the min. quantity of food required to bring about optimal deposition of mineral matter." Conditions under which the method may be applied in the study of the antirachitic properties of foods are being investigated.

A. P. LOTHIROP

Dietary factors influencing calcium assimilation. VI. The antirachitic properties of hays as related to climatic conditions with some observations on the effect of irradiation with ultra-violet light. H. STEENBOCK, E. B. HART, C. A. ELVEHJEM AND S. W. F. KLETZGEN. *J. Biol. Chem.* **66**, 425-40 (1925); cf. *C. A.* **16**, 3937.—"The antirachitic properties of hays are related to their exposure to sunlight. Clover hay made with exposure to sunlight showed considerable calcifying power, while clover hay made in the dark was inactive. Clover hay excessively weathered was reduced in antirachitic action as compared with hay less exposed to dew and rain. The antirachitic action of clover hay excessively weathered was readily increased by irradiating it with a quartz Hg-vapor light. It is not clear whether this was due to an activation of constituents formerly inactive or to a reactivation. Direct irradiation of a milking goat brought about a positive Ca balance even when the animal was receiving the weathered clover which by itself has no beneficial effect. The antirachitic potency of sun-cured hays was too feeble to act as a preventative of rickets in growing chicks even when the H₂O exts. were fed as equiv. to a high concn. of the hay in the ration. It is suggested that the antirachitic requirements of the chicken and the lactating goat are far greater than those of the rat as used in these expts. On account of the prominent rôle played by the element Ca in animal physiology, it appears urgently necessary that the factors operative in producing hay of max. antirachitic potency be thoroughly understood. This is especially necessary because Ca deficiency in feeds is a common occurrence and

with that there is a proportionate increased demand of the animal for the antirachitic factor. These studies are of value directly as well as indirectly in their relation to processes in human physiology." A. P. LOTHROP

Fat-soluble vitamin. XXVI. The antirachitic property of milk and its increase by direct irradiation and by irradiation of the animal. H. STEENBOCK, E. B. HART, C. A. HOPPERT AND ARCHIE BLACK. *J. Biol. Chem.* 66, 441-9(1925).—The antirachitic properties of cow milk can be increased more than 8 times by exposure to radiations of a quartz Hg-vapor lamp and that of goat milk 24 times. This increase can also be rather promptly induced, though to a lesser degree, by direct irradiation of the animal. "Attention is called to the beneficial results to be expected by the dairyman. For man in general the indirect benefits are obvious." A. P. LOTHROP

Studies on cholesterol. I. Synthesis of cholesterol in the animal body. F. S. RANGLES AND ARTHUR KNUDSON. *J. Biol. Chem.* 66, 459-66(1925).—Young rats were placed on a diet free from cholesterol and all other sterols which respond to the Liebermann-Burchard test. They were allowed to reproduce and their young were continued on a cholesterol-free diet. Vitamin A was furnished by alfalfa from which all sterols were removed by prolonged extn. with cold Et_2O (72 hrs.). The amt. of cholesterol found in the tissues of the rats on the cholesterol-free diet did not vary greatly from the normal. The cholesterol content of the adult rat born and raised on a cholesterol-free diet was many times as great as at birth and "the only explanation available at present is that the cholesterol was built up by the animal organism from substances other than sterols in the diet." Cf. Channon, C. A. 19, 3105. A. P. L.

A study of the retention of uric acid during fasting. WM. G. LENNOX. *J. Biol. Chem.* 66, 521-72(1925); cf. C. A. 18, 1700.—"Measurements of uric acid in blood and urine during 21 fasting periods were made. The observed high concns. of uric acid in blood were due to decrease in uric acid excretion. The usual diurnal and hourly variations in excretion were abolished. Although concn. of uric acid in urine was very low (sometimes less than in blood plasma), the kidneys were able to conc. uric acid to a normal extent. Decreased urine vols. seemed to be associated with increased uric acid output. Study of quant. relationships showed that retention was evident first in the plasma; with rising concns. in the plasma an increasing proportion of retained uric acid (up to about 80%) was found within the cells; at the higher levels there was apparent equil. between concn. within and without the cells; the increase of concn. in tissue H_2O , at its peak, was 30% of the increase in plasma; approx. 60% of the uric acid retained during fasting was recovered in the postfasting period, the unrecovered fraction being either retained in the tissues or destroyed. During some of the 24 hr. periods there was considerable shifting of uric acid from blood to tissues and *vice versa*. During fasting a smaller proportion than normal of uric acid injected intravenously was recovered in the urine. Feeding of fat did not relieve retention, whereas, feeding of carbohydrate, thyroid ext., amino acids and protein did. Following ingestion of small quantities of food, there was increased elimination of uric acid without lowering the renal threshold. Following ingestion of atophan, in doses of 4-5 g., there was a lowering of the renal threshold with drainage of uric acid first from the blood and then from the tissues. From the foregoing data it seems evident that variations in excretion of uric acid following the use of various purine-free diets do not mean variations in production, but variations in the amts. of uric acid contained in blood and tissues. The observations suggest the use of a low-fat diet in the treatment of gout. Disturbance in kidney function and in metabolism of the body both played a part in the retention. Of the various possible factors examd., the attending ketosis seemed the most const. It is possible that various interrelated disturbances in oxidation and in the base-acid equil. of the blood and body tissues are involved." A. P. LOTHROP

The effect of vitamin A deficiency upon the character of nitrogen metabolism. AGNES F. MORGAN AND DOROTHY F. OSBURN. *J. Biol. Chem.* 66, 573-94(1925) When young rats are fed a diet adequate in all respects, the % recovery of total N in the form of urea, NH_3 , allantoin, uric acid and creatinine varied between 45 and 61. The relative amts. of allantoin decreased with gain in body wt. and increased with loss in body wt. The av. amt. of N excreted as uric acid was 0.58% and of creatinine 2.87. Upon diets adequate in all respects except as to vitamin A the % recovery of total N ranged between 46 and 59. The relative amts. of allantoin increased with gain, or in most cases lessened loss, in body wt., and decreased with increased loss in wt. The av. amt. of N excreted as uric acid was 0.73% and as creatinine 2.37. With adult rats on an adequate diet the % recovery varied from 51 to 81, amts. definitely larger than were obtained with either group of young animals. The relative amt. of allantoin excreted varied inversely with gain in wt. as with the young rats. The av. amt. of

N excreted as uric acid was 0.61% and as creatinine 3.45. "A theory is advanced to account for these differences between the excretion of allantoin and uric acid in normal and vitamin-A-deficient animals. It is suggested that in the absence of vitamin A the animal organism fails to produce purine-contg. compds. from the ordinary sources, perhaps arginine and histidine, but continues to utilize over again such portions of discarded purine-ring-contg. substances as are ordinarily excreted in the form of allantoin. The portions of these compds. which are oxidized only to uric acid are apparently no longer usable and continue to be excreted in proportion to the amt. of destruction of cellular material in vitamin-A-deficient as in normal animals." Cf. C. A. 20, 936.

A. P. LOTHROP

The relation between the amount of ultra-violet light received by hens and the amount of antirachitic vitamin in the eggs produced. J. S. HUGHES, L. F. PAYNE, R. W. TITUS AND J. M. MOORE. *J. Biol. Chem.* 66, 595-600(1925).—The amt of ultra-violet light which a hen receives is an important factor in detg. the antirachitic vitamin content of the eggs produced when the feed is low in antirachitic vitamin. Thirty min. ultra-violet treatment daily is not sufficient to enable hens to store sufficient antirachitic vitamin in their eggs entirely to prevent rickets in chicks fed rations contg. these eggs, although the severity of the rickets is materially reduced. Eggs from hens receiving sunlight through glass contain practically no antirachitic vitamin. Eggs of low antirachitic vitamin content do not have as high a hatchability as those with high vitamin content, other factors influencing hatchability being const. Cf. C. A. 20, 936.

A. P. LOTHROP

A study of the effect of excessive calcium ingestion on the calcium content of tissues with and without the application of ultra-violet light. W. DENIS AND R. C. CORLEY. *J. Biol. Chem.* 66, 609-17(1925).—The Ca content of the tissues of rabbits receiving daily doses of CaCl_2 or Ca lactate (equiv. to 0.18 g. of Ca) contain no more Ca than those of control animals. The Ca content of the tissues and serum of normal rabbits is not affected by daily exposure to ultra-violet light.

A. P. LOTHROP

The relation of leg weakness in chickens to mammalian rickets. A. M. PAPPENHEIMER AND L. C. DUNN. *J. Biol. Chem.* 66, 717-29(1925).—"Radiographic and histologic study of a series of young growing chicks with experimentally produced leg weakness showed no rachitic changes. The bone lesions found were arrest of osteogenesis, osteoporosis and fibromyxomatous transformation of the marrow. Administration of the active antirachitic concentrate of the non-saponifiable fraction of cod-liver oil did not prevent the onset of leg weakness nor modify the character of the bone lesions. The addn. of whole cod-liver oil prevented leg weakness and brought about normal bone structure. The diet (white corn 97, CaCO_3 2, NaCl 1, skim milk *ad libitum*) which produced typical leg weakness in chickens was fed to young rats for 4 weeks but did not produce rachitic changes in their bones." Withdrawal of the skim milk from the diet of the rats produced pronounced and typical rachitic lesions so that the leg weakness diet is antirachitic with milk and rachitic without.

A. P. LOTHROP

The nutritional requirements of the chicken. VI. Does the chicken require vitamin C? E. B. HART, H. STEENBOCK, J. G. HALPIN AND S. LEPKOVSKY. *J. Biol. Chem.* 66, 813-8(1925); cf. C. A. 16, 2713; 20, 224.—Scurvy does not develop in chicks fed a ration of grains and heated skim milk, presumably free or at least very low in its vitamin C content. Their livers, however, contained an abundant amt. of vitamin C as guinea pigs were cured of scurvy when fed liver from these chicks at a level of 3 g. daily. Similar results were obtained when the ration consisted of purified food materials—dextrin, casein, salts, etc. "Apparently the chicken, like the rat, does not need vitamin C preformed in the diet in the same sense as does the guinea pig; but its presence in large amts. in the livers of chickens even on synthetic diets indicates that it plays some role in its metabolism. Whether the chicken synthesizes this vitamin from an inactive precursor or from some other org. complex cannot at present be stated." A. P. L.

The effect of orange juice on the calcium, phosphorus, magnesium and nitrogen retention and urinary organic acids of growing children. MARGARET S. CHANEY AND KATHERINE BLUNT. *J. Biol. Chem.* 66, 829-45(1925).—A basal diet consisting of oatmeal, rice, flour, bread, potato sugar, oleomargarine fat, lean beef and whole milk powder was ingested by 2 growing girls, 10 and 11 yrs. old, for a preliminary adjustment period and a 3-day collection period. Then 600-700 cc. of orange juice was added to the diet daily and another adjustment and collection period followed. The expt. was repeated after a 2½ month interval. There was an increased Ca retention which was considerably greater than the amt. of Ca added in the oranges and than might be expected from a stimulus to retention caused by a larger Ca intake. More than 3 times as much P was assimilated after addn. of the orange juice, this increase being much more

marked than that in Ca. Mg retention was also increased but to a lesser extent. N assimilation was greater even though the intake was not altered. There were increases in urinary p_H and org. acids and a decrease in NH_3 . The increase in org. acids amounted to approx. 7% of the citric acid of the ingested juice. A gain in body wt. occurred which was 3-4 times as much daily as in the period when oranges were not included in the diet

A. P. LOTHROP

Maintenance values for the proteins of milk, meat, bread and milk, and soy bean curd. MARY S. ROSE AND GRACE MACLEOD. *J. Biol. Chem.* **66**, 847-67(1925); cf. *C. A.* **19**, 1727.—The relative efficiency of milk, meat, bread and milk, and soy bean curd in maintaining N equil. in the adult human subject has been tested in 8 expts. of 12-15 days duration conducted on 4 young women. The same basal ration was used throughout; the energy yield was adjusted to maintain body wt.; and the protein intake was approx. 0.5 g. per kg. of body wt. although the protein intake was 15-20% less than the av. for maintenance on a mixed diet as detd. by Sherman, in no case was there a negative N balance. The food under investigation in each case furnished 97-98% of the total protein of the diet. Changing from meat to milk and then to bread and milk resulted in av. daily storage of 0.06 g. of protein on meat, of 0.55 g. on milk and of 0.1 g. on bread and milk (1.4, 13.3 and 9.7% of the total intake, resp.). Changing from milk to meat made no practical difference as compared; with changing from meat to milk. Fecal N comprized 11-12% of the total intake in all cases except on the soy bean diet in which case it amounted to 24% of the intake. The urinary N averaged 0.06 g. per kg. on all except the meat diet which caused a higher excretion, averaging 0.07 g. Studies of the urinary acidity and NH_3 indicated no great differences in the acid-base balance of the diet. The NH_3 in the urine was somewhat higher on the meat than on the milk diet (16 and 21% in 2 cases). The constancy of the creatinine excretion indicated that there was no essential difference in the metabolism of the different periods. The high fecal N on the soy bean diet may be interpreted to mean a lower biol. value although the soy bean must be regarded as very efficient inasmuch as equil. was maintained on a very low intake; this point will be further investigated

A. P. LOTHROP

The V factor, an injurious substance in the serum of animals with avitaminosis, measured by its biological effect on the growth of the influenza bacillus. W. KALLATH AND B. LEICHTANTRITT. *Centr. Bakt. Parasitenk. I Abt., Orig.* **97**, 65-80(1925). Blood was mixed with agar, heated 1 min. in boiling water, and poured into plates. Blood from normal guinea pigs gave a luxuriant growth of *B. influenzae*. Blood from pigs with mild scurvy gave weaker growth with some involution forms. That from pigs with marked scurvy gave a scant growth with many involution forms. When a pig recovered from scurvy the deleterious effects of the blood disappeared. The addn. of potato water (vitamins?) reactivated the scorbutic blood. Blood from starved pigs had no bad effects. Blood of beriberi pigeons did not weaken growth. It is probable that there is a bacterial growth-stimulating substance not identical with vitamin A or B

JOHN T. MYERS

Effect of salts of zirconium, titanium and manganese on nutrition. CHARLES RICHET, GARDNER AND GOODBODY. *Compt. rend.* **181**, 1105-6(1925).—Three series of 4 dogs each were given the citrates of Zr, Ti and Mn, resp., in doses of 1 g., which for these animals averaged about 0.1 g. per kg. Of the 4 dogs in each series one received the drug every day, the second once in 2 days, the third once in 3 days, and the fourth once in 4 days. The period of trial was from June 14 to Nov. 10. Three additional dogs served as controls. No toxic action was observed. Favorable or unfavorable action was estd. by gain or loss in wt. In general Ti and more especially Zr showed a slightly favorable action on the nutrition. The action of Mn was peculiar in that it had an unfavorable action when administered every day or once in 2 days, but a decidedly favorable action when administered once in 3 or 4 days.

L. W. RIGGS

The influence of the addition of ternary foods to milk upon the retention of nitrogen during growth. E. F. TERROINE AND (Mlle.) ANNE-MARIE MENDLER. *Compt. rend.* **181**, 1176-9(1925).—Young pigs were fed (1) skimmed milk, (2) whole milk, (3) whole milk with cream added, and (4) whole milk with cassava starch added, and the amt. of N retained detd. The figures showed that the retention of N during growth is strongly influenced by the amt. of ternary foods (fats and carbohydrates) in the ration. This suggests that the construction of albumins is a more complex process than the simple modification of the amino acids resulting from the degradation of the ingested proteins, and that the ternary groups carried by fats and carbohydrates play an important role. Whole milk as a ration during growth is decidedly improved by the addn. of cream or starch up to the limit of digestive tolerance.

L. W. RIGGS

Glycogenic reserves and arterial glucose (effective and proteinic) in the course of experimental scurvy. (MME.) L. RABOIN AND J. M. MACHAUX. *Compt. rend.* 181, 1179-81 (1925).—Three series of guinea pigs consisting of 26, 26 and 30 animals each, were fed, resp., a natural ration, a complete artificial ration, and a complete artificial ration deprived of vitamin C for a period of 32 days. At intervals of about 5 days, 3 or 4 animals were killed and the following detus. were made: free blood sugar, proteinic blood sugar, glycogen in the liver and glycogen in the muscles. In the course of scurvy the glycogenic reserves are somewhat less than those of the normal animal. The alimentary disequilibrium, resulting from the total absence of vitamin C from the ration does not appear to prevent the acquisition of the glycogen reserves, nor does it affect appreciably the blood sugar or the proteinic blood sugar. L. W. RIGGS

The water-soluble vitamin content of the velvet bean. W. D. SALMON AND E. R. MILLER. *J. Agr. Research* 31, 793-9 (1925).—Polyneuritic pigeons were restored to apparently normal health by raw and by alc. and AcOH exts. of velvet beans; and pigeons receiving a diet of polished rice were protected against the onset of polyneuritis by 2 g. of raw velvet beans per day. Beans that had been thoroughly extd. with alc. had no protective action when fed in doses of 2-4 g. per day. While small amts. of velvet beans had a protective action, large amts. were harmful and this effect was not entirely overcome by cooking the beans 1.5 hrs. on a water bath, or by autoclaving them for 2 hrs. at 15 lbs. pressure. W. H. ROSS

Irradiation of foodstuffs with ultra-violet light. H. M. M. MACKAY AND H. F. SHAW. *Lancet* 1926, I, 8-11; cf. C. A. 20, 222.—A clinical investigation of the curative value of irradiated food in rickets. F. B. SEIBERT

Ultra-violet irradiation in the activation of cholesterol and foods. A. F. HESS AND M. WEINSTOCK. *Lancet* 1926, I, 12-4.—Vegetable oils, cotton seed oil, growing wheat, green and yellow lettuce leaves could be activated by irradiation. Chlorophyll, hemoglobin, cream, phosphatide of yolk of egg, glycerol and gelatin could not be activated. Refined wheat flour, dried milk and cholesterol were activated, but the latter readily lost its activity if kept in a dry state or suspended in H₂O, but not if dissolved in oil. F. B. SEIBERT

New facts concerning the fat-soluble vitamins. J. C. DRUMMOND. *Lancet* 1926, I, 272-3.—The history of the discovery of the fat-sol. vitamins is briefly outlined. Of these fat-sol. vitamins, vitamin A is responsible for growth, D for antirachitic effect, and E is extremely important in reproduction. They are not identical. Of cod-liver oil, 99% consists of true fats, i. e., glycerides and 1% of unsaponifiable matter. This latter fraction, if prepd. with care so as to prevent secondary changes, such as oxidation, contains all the vitamins. In an attempt to isolate vitamin A by chem. fractionation, 10 kg. cod-liver oil yielded 100 g. active unsapon. matter; pptn. of this with digitonin gave 50 g. inactive cholesterol and 50 g. active material, which on distn. under 1-2 mm. pressure gave 5 g. inactive, b. 180°; 10-15 g. active (with traces of spinacene), b. 180-200°; 15-20 g. inactive (mainly spinacene and batyl alc.), b. 220-80°; at 300° an inactive residue. Vitamin D has proved to be associated closely with cholesterol. If cholesterol is acted upon by ultra-violet light, a substance, so far unidentified chemically, is produced which has antirachitic activity. The vitamin A may be a higher unsaturated alc., since the active fractions contain only C, H and O in this form.

Effect of ultra-violet light on avitaminoses. II. Beriberi in pigeons. Direct irradiation of the skin after removal of the feathers. JAROSLAV KRÍŽENECKÝ. *Arch. grs. Physiol.* (Pflüger's) 211, 663-5 (1926).—The development of beriberi in pigeons and the manifestations of the disturbance are not modified by the direct irradiation of skin with ultra-violet rays. G. H. S.

ANDREW HUNTER

Distribution of nitrogen in urine of ruminants. F. ROGOZINSKI AND M. STARZEVSKA. *Bull. Inter. Acad. Polonaise, B*, 1924, 77-83; cf. C. A. 18, 2363.—When rations rich in protein are given to sheep, the increase in the N content of the urine is

chiefly in the carbamide fraction, and to a less extent in the hippuric acid fraction. The excretion of other nitrogenous substances, in particular uric acid and creatinine, is scarcely affected by increase in the protein intake. B. C. A.

Studies on the adrenaline content of the suprarenal gland. KIICHI TAKAHASHI. *Hoku-Etsu Ig. Kw. Z. Niigata* 37, 257-81(1922); *Japn. J. Med. Sci.* 2, 17.—The adrenaline content of the suprarenal gland of the rabbit is about 0.0825 mg. per kg. of body weight, being equal on both sides and in either sex. After bleeding it decreases, as shown by the lowered blood pressure, and returns to the normal state 48 hrs. later. Elec. stimulation of the splanchnic nerves brings about the increase of adrenaline content in the gland, but that of the vagus has no such effect. Nicotine stimulates the adrenaline secretion for awhile, but atropine has no influence on the adrenaline content and secretion of the suprarenal gland. H. G.

The calcium content of the blood serum. TAKEO INOUE. *Ij. Shb. Tokyo* 1922, 723-35; *Japn. J. Med. Sci.* 2, 17.—By means of I.'s method, a modification of De Waard's method, the Ca content of human blood serum can be measured quantitatively. The Ca content of healthy Japanese adults averages 10.14 mg. in man and 9.83 in woman per 100 mg. blood serum. Its content in the serum of beriberi patients does not indicate any deviation from the normal. H. G.

Intracellular enzymes of the liver, particularly in phosphorus poisoning. STAEMMLER. *Klin. Wochschr.* 5, 134-6(1926).—The oxidase and diastase activity of normal liver cells is markedly inhibited by P *in vitro*. Livers from animals that have suffered with slow P poisoning contain more oxidase than normal livers. The increased oxidase activity is always associated with fatty degeneration. Large doses of P kill before the fatty degeneration has occurred; and in this case the oxidase content of the liver is normal. The diastase content of livers from phosphorized animals is normal. Liver lipase is not sensitive to P. Of particular note is the fact that the results obtained *in vivo* and *in vitro* for oxidase and diastase are exactly opposed. MILTON HANKE

The intestinal wall as assistant regulator of the hydrogen-ion concentration in the organism. W. LÖFFLER. *Klin. Wochschr.* 5, 179-81(1926).—The feces are normally alk.; p_H 7.66-8.04. Ingestion of acid, either NaH_2PO_4 or HCl, gives rise to an acid stool. The p_H may drop to 5.2. The feces becomes acid long before the ingested acid could have traveled to the colon by the intestinal route. The acid is evidently absorbed and then excreted into the colon from the blood. Ingestion of alkali leads to feces that are abnormally alk. Here again the alkali must be absorbed and then be excreted into the colon. MILTON HANKE

Albuminuria of infants. ERNST FAERBER. *Klin. Wochschr.* 5, 181-2(1926). Infants ingest very little fluid during the first few days. Albuminuria is present at birth and continues until the water intake is 9-10% of the infant's body wt. The albuminuria of infants resembles the dehydration albuminurias of adults. M. H.

Is the surface tension of blood serum of constant value? K. BECKMANN. *Klin. Wochschr.* 5, 215-6(1926).—The static surface tension of blood serum is not constant. It changes during the period of food resorption and varies, from the normal range in edema. MILTON HANKE

Alkali reserve in athletes. FULL AND HERXHEIMER. *Klin. Wochschr.* 5, 2-8 (1926).—The alkali reserve of the blood (Van Slyke method) is above normal in well trained athletes. The normal figure is 65. The av. of the values on 13 athletes was 72. Diet is not mentioned. MILTON HANKE

Inner secretion of the sex glands. ESKIL KYLIN. *Klin. Wochschr.* 5, 367(1926).—Aic. exts. of ovary and testicle were prepd. Injection into rabbits of the same sex, e. g., ovarian ext. into females, produces a fall in blood sugar in normal and in diabetic animals. Ovarian ext. produces a rise in blood pressure when injected into castrated males. The exts. lower the blood pressure when injected into man. Boiling for 5 min., cooling for 1 hr. or storing for 2 months at room temps. destroys the active substance in the ext. MILTON HANKE

Fat and the action of the thyroid gland. J. ABRILIN. *Klin. Wochschr.* 5, 367(1926).—Fat seems, in a way, to be antagonistic to the action of the thyroid gland because a high metabolic rate, due to excessive thyroid activity, can be markedly reduced by feeding fat. The thyroid hormone also increases the specific dynamic action of foods. Fat is also antagonistic to the thyroid hormone in this respect. MILTON HANKE

Renal function in persons having only one kidney. NELLIS B. FOSTER. *Arch. Internal Med.* 36, 884-8(1925).—Of the tests performed: concn. test, water and urea excretion tests and the ratio urine urea/blood urea after urea administration only the last revealed consistently a limitation of renal function. MARY JACOBSEN

Intestinal chemistry. III. Salivary digestion in the human stomach and intestines. OLAF BERGHEIM. *Arch. Internal Med.* 37, 110-7(1926); cf. C. A. 1, 2138, 2143; 16, 2894; L. Strauss, *Arch. Verdauungs-krankh.* 33, 163(1924).—Expts. were carried out in persons with normal digestion; the retention stomach tube was used. $\text{Fe}(\text{OH})_3$ was added to the food as a digestion control. Being insol. it always remained with undigested starch. Within 15 to 20 min. after the meal 76% of the starch of mashed potatoes and 59% of bread were converted to maltose and an additional percentage was converted to dextrins. Active amylase disappears as soon as free HCl appears. It was found in contrast to other authors that amylase is inactivated by small quantities of HCl in the presence of starch or of products of its hydrolysis and cannot be reactivated by neutralization. Nor can saliva inactivated by boiling be reactivated by the addn. of small quantities of amylase.

MARY JACOBSEN

Additivity in sugar mobilization. R. W. SEUFFERT AND C. KRÜGER. *Beitr. Physiol.* 3, 85-91(1925).—The expts. on dogs confirmed that *acetamide* (I) and *urethan* (II) have only a mobilizing, not a glycogenetic, effect. The combined action of I, II and *adrenaline* is stronger than the action of I alone but no quant. data regarding the additivity could be obtained. In drawing this conclusion it was assumed that no noticeable sugar formation from fat occurs.

MARY JACOBSEN

The influence of the adrenal function on the ovary. P. G. DAL COLLO. *Folia med.* 10, 609-15(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 121.—The ovaries of mature dogs showed broadening of the *zona germinativa*, increase of the no. of follicles, of which only a few were ripe, and a partial degeneration of follicles as a result of adrenalectomy as well as of intraperitoneal injections of adrenal ext. in increasing doses. In the latter case there was besides that a reduction of interstitial tissue and a thickening of the vascular walls, particularly of the adventitia, but not of the intima.

M. J.

Stomach reaction and chemistry. HANS SCHMIDT. *Arch. klin. Chir.* 130, 307-22(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 274.—A detailed account of the influence of the various stomach operations on gastric acidity.

MARY JACOBSEN

The glucose content of the erythrocytes. PLINIO ATZENI TEDESCO. *Folia med.* 10, 561-71(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 287(1925).—Erythrocytes are permeable to glucose, but contain less glucose than the serum. The method of prepn. and deproteinization applied (details of which are given) precludes injury to the cells.

MARY JACOBSEN

A study in vivo of the interrelation between blood and spinal fluid, and a method of its quantitative evaluation in man. W. SCHÖNFELD. *Dermatol. Z.* 40, 193-200; *Ber. ges. Physiol. exptl. Pharmacol.* 30, 290(1925).—In 17 cases of syphilis *uramin*, a fluorescent dye, appeared in the spinal fluid with a max. intensity 8 to 12 hrs. after the injection of 20 cc. of an 8% soln. Injection of 1% *aesculin* gave a positive result in 5, an ambiguous one in 2 cases out of 15. *Phenolsulfonephthalein* (3 mg.) introduced into the spinal fluid appeared in the urine in 6 to 30 min., with a max. after 1 to 2 hrs. The punctures repeated in rapid succession caused an increase in cell count and protein content of the spinal fluid.

MARY JACOBSEN

The quantitative analysis of woman's colostrum. MASASHI NAKAMURA. *Mitt. med. Fak. Kais. Univ. Tokyo* 32, 235-50(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 367.—The fat content is higher, the lactose content lower (5%) than in permanent milk. The high protein (6-7%) and residual N (over 7%) of the first 2 days reach the normal level on the 2nd to 4th day.

MARY JACOBSEN

Biochemical and serological examination of chicken eggs during hatching. SENJO IZUMI. *Mitt. med. Fak. Kais. Univ. Tokyo.* 32, 197-216(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 383.—Residual and amino N increases, while the total N remains unchanged. Sugar falls regularly until the 10th day, rises from that time on and falls rapidly after hatching. Glycogen increases after the 8th day and decreases after hatching out. The const. diminution of fat which continues after hatching is noteworthy. There is an increase in antitryptic substances, amylase and Forssman antigen. The proteins of the unhatched egg differ antigenically from chicken serum, but they approach it biologically during the incubation period.

MARY JACOBSEN

The p_H of normal horse urine. C. REINHARDT AND F. HUMMELET. *Arch. wiss. prakt. Tierheilk.* 51, 517-24(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 455.—The p_H of normal urine is between 6.8 and 8.4 and is represented by a variation curve, with a max. at 7.6, the ascending and descending branch of which rests on the above 2 values. Work shifts the curve to the acid side, complete rest to the alk.

MARY JACOBSEN

Utilization of acetamide in man. R. W. SEUFFERT AND J. HINZ. *Beitr. Physiol.* 2, 289-94(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 723(1925).—The amt. of volatile

acids in urine increased with the acetamide dose. The increase may be partly due to cleavage processes in the gastro-intestinal tract.

MARY JACOBSEN

Adrenalinemia and arterial pressure. G. MANISCALCO. *Ann. clin. med. e med. sper.* 14, 351-82(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 761.—Destruction of both adrenals by cauterization reduced the arterial pressure of the rabbit from 50 to 25 mm. Normal pressure was reestablished by 0.01 to 0.005 mg. adrenaline. Cauterization of liver, spleen and kidneys reduced the blood pressure only by 7 mm.

MARY JACOBSEN

Thyroid action and products of organ catabolism. J. ABELIN AND R. SATO. *Schweiz. Wochschr.* 55, 45-50(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 770(1925).—Thyroid feeding caused in the rabbit and in the sheep decrease of blood viscosity and of serum proteins, in the beginning also often a fall of sedimentation velocity. The changes occur in phases (decrease, increase, decrease). Discontinuation of thyroid feeding is also attended by blood changes. Since these phenomena appear in all cases of increased catabolism the conclusion is justified that the degradation products participate in the process.

MARY JACOBSEN

The mechanism of production of digestion leucocytosis. V. Action of hydrochloric acid on the behavior of the hematopoietic tissues. C. CIACCIO. *Haematol.* 5, 287-93(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 905(1925).—The effect on the hematopoietic organs of HCl administration is the same as the effect of protein ingestion. It is concluded that the increased HCl secretion after food intake is the cause of alimentary leucocytosis, and that the phenomenon is independent of the digested protein

MARY JACOBSEN

Diuresis. W. NONNENBRUCH. *Erg. inn. Med. Kinderheilk.* 26, 119-206(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 919.—An exhaustive review.

MARY JACOBSEN

Renal and tissue diuresis. A. MUGGIA. *Rif. med.* 40, 1153-6(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 920.—A summary of the work of M. and others. The view is advanced that there is renal and tissue diuresis. Only the essential oil diuresis is considered as purely renal. The extrarenal action of purine derivs. is demonstrated by perspiration and rapidly ensuing diuresis after coffee; the extrarenal loss of water after Hg preps. follows from the decrease of ascites. Combination of diuretics of 2 groups enhances diuresis (euphylline-hypertonic NaCl). Hg preps.-hypertonic NaCl form an exception.

MARY JACOBSEN

The female sexual hormone. III. The effect of the cyclic hormone when administered by mouth. S. LOEWE, F. LANGE AND W. FAURE. *Deut. med. Wochschr.* 52, 310-3(1926).—With mice the authors were able to obtain the typical specific effects of the sexual hormone when the oral method was used; the dose required was 20 times the subcutaneous dose. Fractional doses under certain conditions produce an additive effect.

LOUIS LEITER

The function of the plasma proteins. P. E. HOWE. *Physiol. Rev.* 5, 439-76(1925).—Review with extensive bibliography. The plasma proteins, other than fibrinogen, are stabilizing in their effect on water balance and in their function of a suspending agent for the formed elements. They are probably not to be considered as transition products from food to body proteins, but act as an indirect source of food trephones through the action of leucocytes. It is generally stated that globulins are the carriers of antibodies. This is true as a general statement, but the conditions are complicated.

E. R. LONG

Action of temperature on respiration in vitro of the tissues of homeotherms and of poecilotheims. JEAN ROCHE. *Compt. rend.* 182, 91-3(1926); cf. *C. A.* 19, 2227. Following the technic of Terroine and Roche the consumption of O in vitro per g of fresh tissue per hr. was detd. for the pectoral muscle of the pigeon, and the ischiatic muscle of the frog at different temps. and between the limits of 10° and 30°; the pigeon muscle consumed approx. twice as much O as the frog muscle. The O consumption may be represented mathematically as an exponential function of the temp. These findings are discussed with reference to their bearing on the heat-regulating mechanism of these animals.

L. W. RIGGS

Cholesterogenic function of the spleen; influence of the internal splenic secretion upon the cholesterogenesis in the muscles. J. E. ABELOUS AND L. C. SOULA. *Compt. rend.* 182, 98-100(1926); cf. *C. A.* 18, 2549.—Expts. with dogs indicated that a functional assocn. exists between the spleen and the muscles, and that the spleen plays a role of first importance in the formation of cholesterol. Grigaut and Dejacé (cf. *C. A.* 19, 3303) proved that there is a diminution of the cholesterogenesis in enervated muscles, but an increase in tetanized muscles.

L. W. RIGGS

Test of liver function. I. The Widal hemoclasia. TORU OKA. *Tôhoku J.*

Exptl. Med. 6, 459-87(1925).—Alimentary leucopenia occurs in Eck dogs through the absorption of milk, casein and peptone, and in dogs with the pancreas extirpated through the absorption of sugar, more readily than in normal dogs. Leucocytosis in man and in dogs is provoked by carbohydrates and fats as well as by protein. The so-called Widal hemoclasia is only the alimentary leucopenia. **Test of liver function.** II. **Biliary coloring matter.** *Ibid* 489-521.—A positive reaction for serum bilirubin points to disturbed liver function. If the latter is slight, biliary obstruction does not always occur, but the proportion of urobilin in urine and feces always increases and thus becomes a reliable indicator of disturbed liver function, and also distinguishes between the latter and physiol. hyperbilirubinemia. Dild. bilirubin of herbivora gives a delayed reaction, that of carnivora a prompt reaction whether dild. or not. Bilirubin with prompt reaction may by the addn. of acid be transformed in part into bilirubin with delayed reaction.

L. W. RIGGS

Urea-nitrogen concentration of the blood. I. **Physiological variations of the blood urea-nitrogen and the influence of fixation and anesthesia upon it.** KASANO TASHIRO. *Tôhoku J. Exptl. Med.* 6, 601-29(1925).—The urea-N concn in the blood is equally distributed in the corpuscles and plasma. In case of prolonged fasting the blood urea-N concn. decreases to the min. on the 3rd or 4th day of starvation, after which it increased gradually until death. In the well-fed rabbit the blood urea-N does not appear to change throughout 24 hrs. With 82 normal animals the blood urea-N had a higher value in the warmer months of the year. When the rabbit is anesthetized with Et₂O its blood urea-N concn. is increased. The increase fails to occur when the vagi are previously cut. With Et₂O and with paraldehyde anesthesia the blood urea-N increase does not take place during the pre-narcotic stage. Paraldehyde by the stomach in doses of 1 cc. per kg. does not increase the blood urea-N concn., but in doses of 2 cc. per kg. it causes a marked increase. The increase under anesthesia is attributed to the increase of the central parasymphathetic tonicity. When a normal rabbit is bound, its blood urea-N concn. increases. This increase begins during the binding and if bound for 30 min. it reaches a max. in 30 to 60 min., after release from binding, then falling to normal in several hrs. A binding of 3 to 5 hrs. may double the blood urea-N. This phenomenon is given the provisional name *fixation-hypercarbamidemia*, and is attributed to the central stimulation of the vagus. II. **Effect of caffeine.** *Ibid* 630-43.—A dose of 0.05 g. of caffeine increases the blood urea-N concn. in the rabbit. This increase is arrested and even turned to a decrease by the administration of paraldehyde. The blood urea-N content is not increased but rather lessened by caffeine in atropinized or vagotomized rabbits. Caffeine-hypercarbamidemia is caused by the stimulation of the vagus centers. A large dosage of caffeine causes a decrease of the blood urea-N concn.

L. W. RIGGS

The basal metabolic rate. H. F. MOORE. *Lancet* 1925, I, 219-24.—The theory of "basal metabolic rate" is discussed, especially in its relation to thyroid disease. The *direct* and *indirect* methods for detg. it are given, the various app. are described, and tables of basal heat production standards and calens. are given. The limitations of the method are outlined and it is recommended to be of especial diagnostic value for estg. the degree of thyroid deficiency, of thyrotoxicosis and the results of treatment. It is also useful in differentiating between mild and doubtful cases suspected to have hyper- or hypothyroidism. It is not of great value in diagnosis of frank cases of hyperthyroidism, myxedema or cretinism.

J. B. SEIBERT

The formation of vegetative stimulating substances in active muscle. KENMATSU SHIMIDZU. *Arch. ges. Physiol.* (Pflüger's) 211, 403-13(1926).—Tests made with the perfusion fluid from a resting muscle stimulated indirectly electrically showed that in the fluid obtained at the termination of muscular activity a substance is present possessing properties similar to those of acetylcholine when applied to intestinal and heart preps. In the fluid from the active muscle there is also a substance which stimulates both intestine and heart and whose activity is not modified by either atropine or ergotamine.

G. H. S.

Effect of definite hormones on metabolic physiology. I. **Effects of adrenaline during hunger.** P. JUNKERSDORF AND P. TÖRÖK. *Arch. ges. Physiol.* (Pflüger's) 211, 414-32(1926).—During hunger the administration of adrenaline causes first a marked hyperglucemia, followed by a return to normal with a subsequent hyperglucemia. The time at which the hyperglucemia becomes manifest after the administration of adrenaline varies, apparently being detd. by the nutritional condition, since poorly nourished animals react most promptly. The degree of hyperglucemia is not related to nutritional condition, although the latter does have some effect on its duration. Within limits the amt. of adrenaline administered is without effect upon the time of appearance,

the degree or the duration of the hyperglucemia. As a rule the hyperglucemia is paralleled by a glucosuria. The total N of the blood and the urine N are usually increased during the adrenaline period. The water content of the blood is reduced. Diuresis increases. Changes in the relative wt. of the liver vary with the interval elapsing after the last treatment with adrenaline; after 7 hrs. the wt. is increased (the increase being related to the size of the dose of adrenaline) while after 72 hrs. the relative wt. is diminished. A fatty infiltration of the liver invariably occurs. Seven hrs. after the last dose of adrenaline the glycogen content of the liver is diminished; after 72 hrs. the liver is practically glycogen-free. With large doses of adrenaline the water content of the liver is reduced. Muscle glycogen is reduced. Other organs show no marked deviations from normal. II. Choline during hunger. P. JUNKERSDORF AND ARNO KOHL. *Ibid* 612-35.—Controlled somewhat by the nutritional state of the animal a more or less prompt and intensive hypoglucemia follows the administration of choline. The time of appearance, the degree and the duration of the hypoglucemia are not detd. by the mode of administration. Accompanying the hypoglucemia are changes in total N and water content of the blood; the urine shows an increased excretion of N; and body temp. falls. The wt. of the liver is reduced far below its normal value but its glycogen content is high. The slight reduction in fat may be ascribed to the deprivation of food. The hypoglucemia due to choline is interpreted as essentially an insulin hypoglucemia. G. H. S.

Hyperthyroidization experiments on dogs. III. Thyroid and carbohydrate tolerance. R. E. MARK. *Arch. ges. Physiol.* (Pflüger's) 211, 523-47(1926); cf. C. A. 20, 443.—Alimentary hyperglucemia in normal dogs consequent to the administration of up to 10 g. of sugar per kg. of body wt. usually disappears within 4 hrs., with an administration of between 10 and 20 g. per kg. after 5-7 hrs. Artificially hyperthyroidized animals present a definitely stronger alimentary hyperglucemia; in dogs deprived of thyroid the alimentary hyperglucemia disappears at a definitely slower rate than in normal animals. G. H. S.

Behavior of the lactic acid in the artificially perfused frog muscle. MASAYAKI OKAGAWA. *Arch. ges. Physiol.* (Pflüger's) 211, 577-96(1926).—The amt. of lactic acid appearing from hr. to hr. in the perfusion fluid satd. with O passing through the resting muscle (leg) of the frog shows a continuous decrease. When the muscle is subjected to a rhythmic stimulation the abs. value for the first hr. is increased, but with continued activity the values fall to the same levels as those of resting muscle. If the perfusion fluid contains KCN (0.001 N) in the absence of O (the oxidative processes being completely inhibited) the lactic acid output is markedly increased and remains high just as long as there are any lactic-acid-producing substances remaining within the muscle. The lactacidogen content of the muscle is reduced only by extreme stimulation, and then but slightly. But with long-continued non-exhausting stimulation it tends to increase. The lactic acid content of the muscle increases during activity in case it leads to exhaustion, but continuous activity which does not exhaust the muscle, with continuous and protracted perfusion, leads to a diminished lactic acid content. Repeated perfusion with small quantities of Ringer soln. does not result in any considerable decrease in the lactic acid content of the fluid. G. H. S.

Fatigue of gastric secretion. R. K. S. LIM AND A. C. LIU. *Arch. ges. Physiol.* (Pflüger's) 211, 647-62(1926).—Prolonged treatment with histamine fails to exhaust either the acid or the pepsin secretion of the stomach. In some cases secretory activity slackens; this is due rather to a disturbance in the extracellular secretion mechanism than to a primary damage to the cells. All parts of the stomach respond to the stimulation in the same way. When the acid secretion app. is stimulated the amplitude of the secretion (concn. of HCl) is const. and entirely independent of the strength of the stimulus, but the degree of secretion (amt. of HCl) is variable, being detd. by the intensity of the stimulation. Under physiol. conditions the capacity to secrete acid cannot be exhausted. Stimulation usually increases the amt. of pepsin secreted, but with continued stimulation both the amt. and concn. are reduced. When such a change occurs the concn. is first modified, the amt. being reduced only after a period of some 12 hrs. or more. It is likewise impossible to exhaust pepsin secretion, although the secretory process can be retarded by milder stimulation than is effective upon secretion of acid. G. H. S.

Function of water-soluble nutritional substances in the metabolism of aquatic animals. • VI. Permeability of the skin in fish for solutions of organic food substances (glucose, saccharose, peptone). GRIGORIY CHOMKOVICH. *Arch. ges. Physiol.* (Pflüger's) 211, 666-81(1926).—Expts. with the surviving isolated skin of several varieties of fish showed that the skin of these animals in their normal physiol. activity is able to

absorb sugars and peptone from water. This finding confirms the observation that the absorption capacity of the skin for aq. solns. of foodstuffs, like that of the intestinal epithelium, differs from the usual osmotic processes in that it is associated with a vital function of the skin elements. G. H. S.

A note on the chemical composition and biological activity of liquor folliculi. F. W. HEYL, M. C. HART AND W. B. PAYNE. *J. Am. Pharm. Assoc.* 14, 210-5(1925).—From 230 cc. of follicular fluid from the sow 6% of protein was obtained by pptn. with EtOH: N 14.43 and P 0.095%. The filtrate gave 0.28% more of crude protein by further treatment. The non-protein fractions were tested for certain constituents and the values calcd. to the original fluid: N 0.015, urea 0.01, creatinine 0.005 and phosphatides 0.027%. By subcutaneous injection in an oil base the fat fraction of the fluid gave only a slight prolongation of the estrous cycle of guinea pigs.

H. GIDEON WELLS

The utilization of fat in diabetes. W. R. BLOOR AND E. M. GILLETTE. *Proc. Soc. Exptl. Biol. Med.* 22, 251-3(1925).—Ninety percent removal of the pancreas in dogs caused a great accumulation and slow removal of fat from the plasma. The effect was observed 1 month after operation. Digestion and absorption were unaffected, as were also the other lipid blood constituents and the corpuscle lipoids. C. V. B.

Some reactions in sensitized guinea pigs to the filtrate of scarlatinal streptococcus. A. R. DOCHEZ AND L. SHERMAN. *Proc. Soc. Exptl. Biol. Med.* 22, 282(1925).—Guinea pigs were given injections of filtrate of scarlatinal streptococcus culture. Skin tests of the filtrate were positive in 7 days and reached a max. in 1 month. No reaction was present in controls. Sensitization was also induced by the subcutaneous injection of living or dead cultures. Sensitized animals gave no reaction following the intracutaneous injection of equal parts of filtrate and antitoxin which had been incubated for 1 hr. C. V. B.

The role of accompanying material in the immunization with invertase preparations. A. BACH, W. ENGELHARDT AND A. SAMISSLOV. *Biochem. Z.* 160, 261-8(1925).—Rabbits were immunized with invertase preps. extd. from yeast. Invertase action was diminished in the presence of the serum of animals so immunized. The purer the invertase preps. the less its immunizing power, and some immunity could be induced by invertase inactivated by heat; so immunity by invertase is not produced by the enzyme mol. but by impurities that ordinarily accompany it. F. A. CAJORI

Lactic acid formation during growth. OTTO WARBURG. *Biochem. Z.* 160, 307-11(1925).— δ -Lactic acid was isolated as its Zn salt from Jensen rat sarcoma, growing in Ringer solns. at 38°. The lactic acid produced in 2 hrs. was equal to 15.4% of the initial wt. of the tumor. The Rous hen sarcoma produces lactic acid at about 8% of its wt. per hr. F. A. CAJORI

Analytical studies on the antihemolytic action of volatile chemicals especially benzene. K. IWAI. *Tokyo Ig. Kw. Z.* 36, 8-9(1922); *Japanese J. Med. Sci.* 2, 115(1924).—The hemolytic action of serum can be diminished or completely prevented by the addn. of C_6H_6 , $C_6H_5CH_3$, $C_6H_5(CH_3)_2$, $CHCl_3$ and benzine. If the volatile chemical is removed, in benzine by centrifuging, the hemolytic power of the serum is restored. Benzene causes a deviation of complement and on its removal the complement is again able to take its part in the hemolysis phenomenon. F. A. CAJORI

A program of research on the action of light on living matter, with especial reference to application in methods of therapy. BRIAN O'BRIEN. *Am. Rev. Tuberculosis* 11, 486-91(1925).—An outlined plan of study is given in which is considered the known radiation spectrum from X-radiation through visible to extreme infra red in its effect upon elementary forms (bacteria, protozoa, nemathelminthes, arthropoda and amphibia), mammalian forms (normal and pathologic) and the local action of light on vertebrate tissues (intact and *in vitro*). H. J. CORPER

Tuberculo-complement-fixation and inhibitive tests. A. H. W. CAULFIELD. *Am. Rev. Tuberculosis* 11, 508-38(1925). H. J. CORPER

The excretion of specific substances of tubercle bacilli in the urine. L. DIENES AND J. FREUND. *Am. Rev. Tuberculosis* 12, 35-40(1925).—All attempts to demonstrate the presence of substances possessing a tuberculin effect on tuberculous guinea pigs, either in the urine of patients with extensive tuberculosis or those receiving during sp.

therapy considerable amts. of sp. substances, were negative. No demonstrable amts. of the sp. substances were present in the blood serum and urine of tuberculous guinea pigs killed by the injection of aq. ext. of tubercle bacilli, while in the urine of normal guinea pigs similarly injected the sp. substances were present. H. J. CORPER

The potency of the watery extract of saprophytic acid-fast bacilli as tuberculins and as antigens in complement fixation. L. D. SCHEFF. *Am. Rev. Tuberculosis* 12, 45-8 (1925).—There exists a close quant. parallelism in the effectiveness of watery exts. of saprophytic acid-fast strains of tubercle bacilli in the complement-fixation test with that of the ext. of the tubercle bacillus, and a marked quant. discrepancy in the tuberculin effect, the exts. of the saprophytic strains having little tuberculin effect only. The skin sensitiveness of guinea pigs treated with killed bacillary material indicates that the material substrate giving the reaction with exts. of saprophytes as compared to tubercle bacilli are not the same and are probably due to different immunological effective groups of protein substances. H. J. CORPER

The agglutination of tubercle bacilli. J. FREUND. *Am. Rev. Tuberculosis* 12, 124-41 (1925).—Suspensions of whole tubercle bacilli agglutinate by electrolytes when their potential is below —13.0 millivolts. NaCl and CaCl₂ cause no agglutination even below this. Some suspensions of one strain studied were agglutinated by CaCl₂ and MgCl₂ at a concn. $\frac{1}{16}$, $\frac{1}{32}$ and $\frac{1}{64}$ mol. Defatted tubercle bacilli acted similarly. Agglutination of lipid suspensions by electrolytes occurs when the potential of the particles is reduced below 15 millivolts, with the above 3 salts. With immune serum sensitized tubercle bacilli are agglutinated whenever the potential is below 13 millivolts, with the 3 salts. Defatted tubercle bacilli sensitized with immune serum act similarly. Normal and immune sera decrease the actual potential of lipid particles. Both agglutinate the lipid particles and normal serum decreases the critical potential for agglutination to 7 millivolts. With immune serum, sensitized lipid particles are agglutinated by NaCl at concns. above $\frac{1}{1000}$ mol., by CaCl₂ above $\frac{1}{4000}$ mol. and by CuSO₄ above $\frac{1}{16,000}$ mol. The isoelec. points of the strains were found between p_H 2.8 and p_H 3; of the defatted bacilli close to 2.8; of lipid particles prepd. from an alc. ext. near 1.5; and particles from ether ext. near 1. The detns. were made by cataphoresis. These observations support the assumption of a protein surface of the bacilli. H. J. CORPER

Complement fixation in tuberculosis. III. Studies on the nature of the antigen. MAX. PINNER. *Am. Rev. Tuberculosis* 12, 142-55 (1925); cf. *C. A.* 19, 2979.—The main complement-fixing substances derived from tubercle bacilli are associated with the fraction practically insol. in acetone, ether and CHCl₃, and sol. in alc. No proof is given that the alc.-sol. substances contain the only antigenic principle, but no ext. from which these substances have been removed contains a sufficient amt. of antigenic power to serve as antigen in complement fixation. Evidence is presented that the degree of dispersion plays an important role in the antigenic value of lipoidal tuberculosis antigen. The protein substances exert an inhibiting influence on the lipoids in complement fixation. No evidence was found that certain sera from tuberculosis patients react only with protein and others only with lipoidal antigen. **IV. Studies on the nature of the antibody.** *Ibid* 233-41.—Sera of tuberculosis patients with positive complement fixation, digested with trypsin and dialyzed until free from protein and protein-split products, still contain complement-fixing antibodies. The complement-fixing antibodies are, therefore, not of the nature of globulins but are either lipoids or proteins (with the CO-NH linkage) not broken up by the action of trypsin. Complement-fixing antibodies have no quant. or qual. relation to the ethylbutyrases ("lipases"). True lipases with a sp. action on tubercle bacillus lipoids were not detected in sera with complement-fixing qualities. The phenomenon, that sera of tuberculosis patients, which are neg. 24 hrs. after the withdrawal of the blood and become pos. after a week or more, is not specific for tuberculous serum, the same occurring, although in smaller percentage, in sera of undoubted non-tuberculous patients. Complement-fixing antibodies may readily be destroyed by ether which excludes the use of ether for extn. in any exams. for complement-fixing antibodies. H. J. CORPER

The effect of the oral administration of calcium lactate and thyroid extract on the calcium content of the blood serum in pulmonary tuberculosis. M. M. TEMITZ. *Am. Rev. Tuberculosis* 12, 222-7 (1925).—Ca lactate and thyroid ext. administration have no effect upon the serum Ca figures in pulmonary tuberculosis. The markedly active toxic cases of pulmonary tuberculosis showed a marked drop below the normal serum Ca figure, averaging about 25%. This apparently indicates that there is a decided loss of Ca from the blood in the terminal stages of pulmonary tuberculosis. H. J. C.

Oxidation and reduction at the site of a tuberculous lesion. WM. C. WHITE, M. L.

SMITH AND M. X. SULLIVAN. *Am. Rev. Tuberculosis* 13, 77-83(1926).—A series of observations is recorded in support of the suggestion that, since, in the conjunction of the tubercle bacillus and the monocyte in their commensal existence, there are operating 2 different oxidation and reduction mechanisms—the monocyte in common with other body cells contg. glutathione, the tubercle bacillus contg. no glutathione. There is a possibility, in the competition of these 2 mechanisms for available labile H, of explaining the observed alteration in the structure of both organisms.

H. J. CORPER
Treatment of tuberculous pyopneumothorax with Pregl's iodine solution. U. WINKLER. *Beitr. Klin. Tuberk.* 59, 218-27(1924).—Favorable action of I soln. upon purulent pleuritis is due to the high CO₂ content of the pyopneumothorax. CO₂ in lab. tests markedly activates the Pregl soln. (C. A. 16, 2691) (aq. soln. contg. 0.035 to 0.04 % free I, with Na ions, I ions, hypoiodite and iodate ions) but not so other I solns. A reinforcing of the I action of the Pregl soln. by introducing CO₂ into the pleural space is superfluous since any excess is rapidly absorbed. The I in Pregl soln. is quickly combined by the tissues and, therefore, posture is used to have the entire diseased pleura come in contact with the soln. immediately after injection. I action persists for 2 to 3 days.

H. J. CORPER
Liver changes and liver function in chronic pulmonary tuberculosis especially with reference to uribilinuria. WALTER LANDAU. *Beitr. Klin. Tuberk.* 61, 29-54 (1925).—The liver in cases of chronic pulmonary tuberculosis shows manifold changes which bear no definite relation to the form of the disease. While the levulose test and chromocholoscropy give no information of diagnostic value in pulmonary tuberculosis regarding liver function disturbances, the urobilinuria is considered the most valuable liver function index. Only a quant. urobilin study possesses value. On account of the impossibility of establishing a pure urobilin scale the term "urobilin unit" is utilized as indicating the amt. of urine divided by the diln. figure. The significance of uribilinuria in pulmonary tuberculosis cannot be detd. from later postmortem findings but rather by means of clinical comparison since it is a labile reversible symptom dependent upon circumstances of stasis. Prognostic conclusions cannot be drawn from the presence of uribilinuria.

H. J. CORPER
The tuberculin problem. VII. Tuberculin reaction and the blood protein picture. A. V. V. FRISCH AND S. BAUMGARTNER. *Beitr. Klin. Tuberk.* 60, 163-71(1924).—The total protein content of the blood varies following tuberculin injection without visible individuality. In almost all cases changes in the blood protein occur after doses which occasion neither general, focal nor local reaction. Likewise, under the same conditions the fibrinogen content changes. In the course of changes of the blood protein picture in one and the same individual there are quant. differences, but qual. the reaction is the same. A parallelism between the pyrexia and fibrinogen curve does not occur in the same individual. To answer satisfactorily the question of the relation of the blood protein reaction to special forms of pulmonary disease there are required many more examns., although it appears that in general active processes cause an earlier increase of the fibrinogen content after tuberculin injection, while in latent or stationary processes the increase is less and more gradual.

H. J. CORPER
The action of tuberculin on the protein decomposition of the liver. R. BIELING AND S. ISAAC. *Beitr. Klin. Tuberk.* 60, 271-5(1925).—The total N, residual (non-coagulable) N and percent relation between the 2 was studied in the liver of normal and tuberculous guinea pigs, untreated and treated with tuberculin. The tuberculin injections in the tuberculous animal caused a splitting of the proteins of the liver as indicated by the N detns. while in normal animals this did not occur.

H. J. C.
Specificity of the tuberculin reaction. H. SELTER AND TANCRE. *Beitr. Klin. Tuberk.* 60, 439-48(1925).—Non-specific bacterial proteins and tubercle bacillus preps. were tested comparatively in tuberculous infected individuals. Of the non-sp. bacterial proteins those from the colon bacillus proved most active, less so were those from chelonin bacilli and still weaker from acid-fast milk bacilli. Between the reactions of the tubercle bacillus protoplasm and the colon bacillus protoplasm first examns. seemed to show no differences, but clinically there was a different course of the reaction in that the tubercle bacillus reaction developed slower. The non-sp. bacteria resulted in a height of the reaction occurring in 24 hrs. which then rapidly subsided. After subcutaneous injection of old tuberculin in active cases of tuberculosis old inflammatory lesions caused by the tubercle bacillus as well as by the colon and other bacilli again flared up. This flare up did not occur after the subcutaneous injection of colon or chelonin bacillus protoplasm, but even these caused marked general reactions. Histological examns. of the excised reaction sites showed no differences, resembling in all cases the structure of the tubercle.

H. J. CORPER

Blood uric acid metabolism in pulmonary tuberculosis. GEORG KELEMEN AND CLARA SANDOR. *Beitr. Klin. Tuberk.* 60, 488-92(1925).—In 20 male tuberculous patients studied in various stages of the disease, but in all of whom there were severe destructive processes, it was found that the blood uric acid in $\frac{2}{3}$ of the cases was only slightly above the lower values of the normal. In a third of the cases even with the full diet the figures were below the normal. The duration and stage of the disease, as well as the pyrexia, seemed to be without influence upon the uric acid. H. J. CORPER

Blood determinations in tuberculosis. E. BRIEGER. *Beitr. Klin. Tuberk.* 61, 2-8(1925).—The total blood vol. was detd. by the Congo red method of Griesbach, the erythrocyte vol. in hirudin blood by means of the Bönninger tubes, and the serum protein refractometrically. In chronic pulmonary tuberculosis there was no increased concn. of the blood as a result of water loss. In advanced cases with increased serum protein values the diminution in the erythrocyte vol. indicates an increase of the plasma vol. The plasma and total blood vol. did not diminish correspondingly to the loss of body weight. The polyglobia in tuberculosis must be considered a genuine erythrocytosis. H. J. CORPER

Sodium chloride and water content of the tuberculous organism. E. BRIEGER. *Beitr. Klin. Tuberk.* 61, 9-18(1925).—The H_2O and NaCl of the tissues of the tuberculous organism are probably diminished, while the blood is not diminished in water or NaCl. The binding of water and NaCl in the tissues of the tuberculous organism is altered. In spite of the higher concn. of the formed elements and the serum proteins, the blood is not dild. The concn. of the blood is the result of a genuine hyperproteinemia in which the normal total blood vol. remains unaltered. An increased administration of water and NaCl alone cannot alter this condition since they will not occasion a normal binding of the water and NaCl in the tissues. J. H. CORPER

Basal metabolism in tuberculosis. W. LANZ. *Beitr. Klin. Tuberk.* 61, 97-121(1925).—The studies were performed with the Krogh-Libesny app. Early tuberculosis gave normal respiratory values. Clinical healed cases of tuberculosis revealed a few with increased metabolism, probably explicable on the existing thyreotoxic condition. Productive acinous nodose forms showed marked gaseous metabolism increase, with the highest values being found in exudative nodose forms. In collapse therapy the metabolism correlated with the clinical findings. After the operation the gas metabolism gradually diminishes. It was significant that at times in early cases, in which physical methods were negative but an active tuberculosis was being dealt with, there was an increased metabolism. H. J. CORPER

The action of tuberculin preparations upon reduction by bacteria. R. BIELING. *Beitr. Klin. Tuberk.* 61, 183-6(1925).—Living bacteria and cells from warm-blooded animals transform aromatic nitro combinations (nitroanthraquinone) into amino combinations (red aminoanthraquinone). These reduction processes can be favored by small amts. of old fluid nutrient media. These enhancing substances are elaborated by various bacteria including the tubercle bacillus. Since tuberculin in the body of tuberculous animals can cause marked dissimilatory changes in the proteins, the question was raised whether the active substances are identical. The reduction-enhancing substances were found not identical with tuberculin, but are non-sp. substances. The reduction method, therefore, is suitable for the detn. of the purity of tuberculin. H. J. CORPER

Secretin. VI. Its influence on the antibodies of the blood: agglutinin. A. W. DOWNS AND N. B. EDDY. *Am. J. Physiol.* 71, 40-3(1924); *Physiol. Abstracts* 10, 212. Rabbits injected daily with a secretin prepn. (15 mg. per kg. in warm normal saline) develop more agglutinins to *B. typhosus* than controls injected with the killed culture only. The difference between the agglutinating powers of the 2 groups is greatest at the end of the first week. VII. Complement. A. W. DOWNS, N. B. EDDY AND R. M. SHAW. *Ibid* 44-5.—The complement from the sera of the same rabbits was estd. by its hemolytic action on washed sheep's red corpuscles. There was no increase in the amt. of complement in the serum of the rabbits receiving the secretin injections nor in that from the controls. VIII. Hemolytic amboceptor. *Ibid* 46-8.—The rabbits used in these expts. received an injection of washed sheep's corpuscles; and half of them were also injected daily with the secretin prepn. The hemolytic power of the serum against sheep's corpuscles increase 800 times in the controls, and 100 times in those animals receiving the secretin injections. H. G.

The adsorption of hemolysins. A. H. ROFFO AND B. BARBARA. *Bol. inst. med. expil.* 1, 280-5(1925); *Physiol. Abstracts* 10, 191.—Hemolysins for sheep's erythrocytes are quantitatively adsorbed from rabbit serum by animal charcoal. H. G.

Surface tension in the Wassermann test and in flocculation reactions. G. PARRINO

AND F. BRANCATO. *Boll. ist.sieroterapico Milanese* 4, 27-33(1925); *Abstracts Bacteriol.* 9, 178.—In a Wassermann system during the course of the reaction there is a lowering of surface tension which is greater in positive than in negative systems. In flocculation reactions there is an increase of surface tension in both positive and negative systems, due to evapn. of alc., but the increase is less in the positive systems, since in these, flocculation tends to lower the tension. The amt. of variation in tension in flocculation reactions is greatest in the Meinicke test, less in the Sachs test and least in the Dold test, depending apparently on the evapn. of the balsam and alc. H. G.

Post-operative acidosis in children. P. C. JEANS AND K. H. TALLERMAN. *Brit. J. Diseases Children* 21, 268-75(1924); *Physiol. Abstracts* 10, 212.—Analysis of blood and of urine before and after operations of various kinds showed that the lowering of alkali reserve is due only in small measure to acetone bodies or to lactic acid. There was an increased phosphate excretion with a lowered blood phosphate, and an increased excretion of org. acids. Conclusion: The lowered alkali reserve is due to some unidentified factor. H. G.

Action of dog serum on human blood. E. RAMIREZ. *Rev. Mexicana Biol.* 5, 253-8 (1925); *Physiol. Abstracts* 10, 149.—Dog serum agglutinates human erythrocytes even in a 1.5% soln. H. G.

The effect of thyroparathyroidectomy on body activities. O. O. STOLAND AND H. L. BRYANT. *Univ. of Oklahoma Bull.* 5 [N. S.] No. 330, 51-8(1926).—The total N, urea N, uric acid and sugar content after thyroparathyroidectomy were normal. The O content and capacity of the blood and the metabolism increased. *Alkalosis* did not always accompany tetany. The subnormal blood pressure following thyroparathyroidectomy may rise after several hrs. of tetany. A meat diet and the oral administration of Ca lactate proved most efficacious in preventing tetany and prolonging life. ARTHUR GROLLMAN

The peroral application of tuberculin. A. REBAY. *Klin. Wochschr.* 5, 69(1926).—A report of one case in which tuberculin was unquestionably active when given by mouth. MILTON HANKE

Metabolism pathology of pyloric spasm. H. VOLLMER AND J. SEREBRIJSKI. *Klin. Wochschr.* 5, 70(1926).—Ten cases of pyloric spasm were studied. The urine was usually alk. The p_H was usually above 7.4 and was, not infrequently, 8.0. The alky. was due to fixed alkalies; NH_4^+ was usually absent. Chlorides were usually absent or present only in traces. The alkali reserve of the blood was abnormally high, values of 100 being not uncommon: p_H normal. Blood chlorides were markedly reduced. Blood Ca, K and P were normal, residual nitrogen was subnormal. Tetanic symptoms were always absent. The acidity of the gastric juice was subnormal. The cases were treated with human milk that had been acidified with HCl until the buffers had been completely neutralized. None of the cases was lost. In this case the pyloric spasm was reduced by administering acid. HCl is known to reduce the contractions of the pylorus and the movements of the stomach in animals. MILTON HANKE

Blood volume determinations, by the dye method, in leucemia and other splenomegalias. ENRICO GREPPI. *Klin. Wochschr.* 5, 110-11(1926).—The total blood vol. detd. by the Congo red method is 7-8% of the body wt. In leucemia, this method gives a value of 12-14%, which would indicate a tremendous hydremia. The refractive index and the erythrocyte count show that a hydremia does not exist. In leucemia, and in other conditions in which the spleen is enlarged, Congo red must be removed from the circulation very rapidly, perhaps by the enlarged spleen. MILTON HANKE

Characteristic blood sugar reaction in cases of ulcus ventriculi. W. SCHARPFF. *Klin. Wochschr.* 5, 138-9(1926).—Ingestion of 80 g. levulose in 300 cc. H_2O by a normal individual does not lead to hyperglucemia. Similar treatment always leads to hyperglucemia in patients afflicted with gastric or duodenal ulcer. M. H.

Occurrence of free phenol in the blood in cases of renal insufficiency. ERWIN BECKER AND STILLFRIED LITZNER. *Klin. Wochschr.* 5, 147(1925).—Phenol can be demonstrated in the blood in cases of renal insufficiency long before the uremic stage has been reached. The circulating phenol, together with other poisons of intestinal origin, may be the causative agents in uremia. MILTON HANKE

The cause of diabetic coma. J. ST. LORANT. *Klin. Wochschr.* 5, 216-21(1926).—Of the theories as to the cause of diabetic coma, the most prevalent are those of Stadelmann and of v. Noorden. S. ascribes the coma to a supreme acidosis, the H ion being the toxic agent, while N. believes that the ketone bodies, particularly β -hydroxybutyric acid, are inherently poisonous. Still, it is a well-recognized fact that administration of alkali does not cure coma. That the ketone bodies are not the causative agents is most conclusively proved by the fact that coma may occur without ketosis. The con-

version of glycogen into CO_2 , H_2O and energy occurs predominantly in the muscle tissue. Diabetes is associated with an imperfect functioning of muscle tissue. The most vital body functions, *e. g.*, blood circulation, vascular tonus and respiration, are carried on by muscle tissue. It is not surprising, then, that coma and death should occur when the muscle tissue ceases to function properly. Anything that tends to increase muscular tonus, *e. g.*, agents that elevate blood pressure, will temporarily arouse diabetics from the state of coma. The relation of glucose to health and disease can be expressed algebraically as follows: $GO \div GI = F$ (oxidation, glycogen synthesis) $\div F_1$ (food carbohydrate, glycogen catabolism, protein carbohydrate) = 1. O = outflow, I = influx, G = glucose and F = function. Any change in the normal balance, such as the intake of carbohydrate, will have to be associated with other changes, as represented in the formula, to keep $GO/GI = 1$. In diabetes both items in the numerator are greatly reduced. The balance is upset. The high blood sugar value is maintained in an effort to increase the possibility of oxidation and glycogen synthesis. MILTON HANKE

The polyphase action of hormones. V. M. KOGAN, M. J. KAMENNEW AND N. B. MANTZ. *Klin. Wochschr.* 5, 221-4(1926).—The salivary secretion in dogs, under the influence of K, Ca, adrenaline and insulin, was investigated. The substances were injected in, possibly, every conceivable combination and in different quantities so that the number of expts. are large. They all affect salivary secretion and the effect of each is modified by the presence of any of the others. The reaction obtained depends upon the time interval that elapses between the injection of any two or three of the substances. A short summary is hardly possible. MILTON HANKE

The relation of the balance between cholesterol and cholesterol esters, in the blood and serum, to liver function. S. J. THIANNHAUSER AND HANS SCHABER. *Klin. Wochschr.* 5, 252-3(1926).—Blood normally contains cholesterol and cholesterol esters. In hepatopathies, the total cholesterol is usually not changed; but the amt. of cholesterol esters is greatly reduced and may even be *nil*. MILTON HANKE

The source of oxalic acid in oxaluria. F. PICCININNI AND E. LOMBARDI. *Klin. Wochschr.* 5, 260-3(1926).—See C. A. 20, 69. MILTON HANKE

The diagnostic value of the sero reaction of Meinicke. ANT. FABIAN. *Bratislavské Lekárske Listy* 4, 87-92(1924).—F. examd. 1571 cases simultaneously by the Bordet-Wassermann and the Meinicke tests. In 75.24% of the cases the results were negative by both reactions and in 21.70% both gave positive tests. In 3.06% of the cases the results were opposite. WILLIAM J. HUSA

Changes in the tissues and in lipoids of mice and rabbits produced by feeding fat, cholesterol and scarlet red. F. KLINGE AND L. WACHER. *Krankheitsforschung* 1, 257-85(1925).—Mice fed with fat, cholesterol, and scarlet red show a deposit of neutral fat, and of cholesterol esters in the fat tissues and in the liver, while the reticulo-endothelial cells and Kupfer's star cells contain lipid pigments. In rabbits the lipid pigments are found especially in the liver cells. Mice excrete scarlet red in the bile, through the kidneys and through the skin; cholesterol in the bile and as ester through the sebaceous glands. Rabbits suffer from cholesterolemia because of their inability to eliminate cholesterol rapidly enough. There are pathological changes in the liver when mice are fed on cholesterol and scarlet red; in herbivorous animals like rabbits these changes occur with cholesterol alone. P. Y. JACKSON

Acidosis in the newborn. The role of the various blood constituents (hemoglobin, blood cells, carbon dioxide, salts) in the regulation of the blood reaction. ARVO YLPPÖ. *Acta paediatr.* 3, 235-60(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 742-3(1925). The p_{H} of blood cells and of CO_2 -free blood serum from the cord are lower than the corresponding values in the newborn a few hrs. or days after birth or in the mother. The alky. of CO_2 -free serum is reduced by the addition of erythrocytes. Cells hemolyzed by saponin have a lower p_{H} than intact ones, the lowest values being again encountered in cord blood cells. The p_{H} differences are smaller in the CO_2 -free bloods, because of the buffer action of hemoglobin. Y. concludes that the new born has a tendency toward acidosis, the latent source of which is the erythrocytes. MARY JACOBSEN

The stability of blood suspensions in the course of experimental acidosis. G. DI MACCO. *Ann. clin. med. e. med. sperim.* 14, 303-10(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 741(1925).—Injection of 0.28 to 1.5 g. Na butyrate or isobutyrate causes decrease of sedimentation velocity. The contrary effect is produced *in vitro*. MARY JACOBSEN

The calcium content of the blood in various diseases of the skin, based on an analysis of 100 cases. H. J. SCHWARTZ AND O. L. LEVIN. *Arch. Dermatol. Syphilol.* 10, 544-50(1924); *Ber. ges. Physiol. expil. Pharmacol.* 30, 442(1925).—The blood Ca

was low in acne, eczema, furunculosis and folliculities, and, against expectation, normal in urticaria and similar diseases. An intimate relationship does not seem to exist.

MARY JACOBSEN

The lipid partition in blood in health and disease. B. L. OSER AND W. G. KARR. *Arch. Internal Med.* 36, 507-15(1925).—In normal persons an av. of 68% of the total blood cholesterol (I) is present in the plasma. In 2 cases it was very low. The concn. of lipid P (II) in cells varies within narrower limits than in the plasma and is 1.5 to 2 times as high as in the plasma. The cell II amounts to 50 to 60% of the total II of the blood. The ratio I/II is about 6.1 in the cells, about 17.8 in the plasma and less const. in the latter. In normal whole blood it is quite const. around 11.3. These data are different from those of other authors and do not permit a conclusion as to a const. cholesterol-lecithin relation and an antagonism based on it. In diseases with lipemia, such as uremia, pernicious anemia, jaundice, cholelithiasis and diabetes the cell II showed considerable variations especially in cases with a low blood cell count.

M. J.

Diseases of the liver. IV. Functional tests in cases of carcinoma of the liver and biliary tract. C. H. GREENE, C. S. McVICAR, WALTMAN WALTERS AND L. G. ROWN-TREE. *Arch. Internal Med.* 36, 542-60(1925); cf. C. A. 19, 3110. —The serum bilirubin detn. and the phenoltetrachlorophthalein test, especially the latter, permit an early diagnosis of carcinoma of the liver and biliary tract and are valuable in absence of clinical evidence. In cases with jaundice the tests, particularly the bilirubin test, do not afford a differential diagnosis. They are not always positive in malignant liver involvement.

MARY JACOBSEN

Nutritional changes in exophthalmic goiter. The effect of Lugol's solution. C. C. STURGIS AND J. A. GREENE. *Arch. Internal Med.* 36, 561-78(1925).—It was found in accordance with previous investigations that in order to maintain body weight in a patient with exophthalmic goiter and increased metabolism the food intake must be 75 to 100% above the basal metabolism. Lugol's soln. given before the operation decreased the metabolism and reduced the postoperative loss of weight from 5.2 to 2%. In 18% of cases there was even a gain in weight.

MARY JACOBSEN

Lipemia and the reticulo-endothelial apparatus. B. S. OPPENHEIMER AND A. M. FISHBURG. *Arch. Internal Med.* 36, 667-81(1925).—In exptl. lipid feeding and in diseases with increased lipemia (obstructive jaundice, diabetes, nephrosis), lipoids are stored in the reticuloendothelial cells. Xanthomas, or lesions consisting of aggregates of "foam cells" (large clear cells filled with lipoids) appear in various organs, spleen, liver, skin and arterial walls. The lipoids stored are neutral fats, cholesterol and phosphatides. Lipemia may or may not be associated with xanthosis, the yellowish discoloration of palms and soles, which is caused by the increase of the lipochrome (carotin, xanthophyll) content in the blood. Gaucher's disease is also characterized by lesions consisting of foam cells. The disturbance of the lipid metabolism is here, however, primary and constitutional. The lipoids stored are cerebroside and other complex lipoids not detectable by staining.

MARY JACOBSEN

The non-specific protein reaction. FLORENCE B. SEIBERT. *Arch. Internal Med.* 36, 747-8(1925); cf. C. A. 19, 2221, 2849.—A criticism of Ling's work.

M. J.

The antigenic property of pollens. H. L. HUBER AND K. L. KOESSLER. *Arch. Internal Med.* 36, 751-61(1925).—"If suitable procedures are followed the antigenic property of pollens can be demonstrated in specifically sensitized animals by: production of characteristic anaphylactic phenomena; positive uterine strip reaction; positive bronchoconstrictions; and production of sp. antibodies giving precipitin, complement fixation and passive sensitization reactions. The response of sensitized uterine strips to *Ambrosia trifida* and *Ambrosia elatior* and to *Helianthus annuus* is sp." The antigenic property of pollens makes the anaphylactic nature of pollen disease probable. *Zea mays* pollen contains an oxytocic principle.

MARY JACOBSEN

The effect on parametria of blood serum, especially from patients with carcinoma. GENEVA A. DALAND. *Arch. Internal Med.* 36, 762-9(1925).—Parametria form vesicles when mixed with blood serum; the rate of formation is an index of toxicity. Menstrual blood serum is slightly more toxic than normal. In diseases the toxicity is equal to (carcinoma) or higher or lower than that of normal serum. Diln., presence of hemoglobin, irradiation by ultra-violet or Röntgen rays diminish the toxicity.

M. J.

Non-specific desensitization therapy in allergic asthma. The eosinophilic index as a guide to intramuscular injection of venom protein, with case report. R. H. SPANGLER. *Arch. Internal Med.* 36, 779-87(1925).

MARY JACOBSEN

The value of the icterus index in differentiating anemia. A. V. ST. GEORGE AND A. LINCOLN BROWN. *Arch. Internal Med.* 36, 847-56(1925).—The normal range of icterus index detd. by a modification of the Meulengracht method was 3.5 to 5.5 with an av.

of 4.4 for 120 cases. The index is above normal in hemolytic anemia, 8 to 12.5 in pernicious anemia, and below normal in secondary anemias. Besides these sp. diseases the index is increased in pneumonia, cardiac insufficiency and chronic sepsis especially in the biliary system and lowered in hemorrhage, especially slow const. bleeding. The index may serve as a prognostic in anemias and a guide for transfusions. M. J.

The concentration of the blood and the urine in diabetic toxemia. H. A. BULGER AND J. P. PETERS. *Arch. Internal Med.* 36, 857-73(1925).—The Na and Cl concn. of the urine is extremely low in diabetic toxemia with blood dehydration and increases rapidly on treatment along with the diln. of the blood. "There is no relationship between the changes in the blood and in the urine and none of the changes appears to be significantly affected by the presence or degree of hyperglucemia or glucosuria." The administration of large amts. of fluid and carbohydrates is recommended, the latter as a means of reducing not only ketosis but also toxic destruction of proteins.

MARY JACOBSEN
Hyperglucemia. I. The relative blood volumes in diabetes mellitus. L. E. FOSHAY. *Arch. Internal Med.* 36, 889-96(1925).—Young patients respond to hyperglucemia with tissue dehydration and anhydremia; old ones, especially those with advanced arteriosclerosis, exhibit blood diln. on account of the absence or only slight degree of polyuria. In severe acidosis there is always anhydremia. The severity of both conditions depends on the degree of hyperglucemia and the rate of onset. Insulin and diet tend to restore the normal water balance, while relapses are always attended by a return to the blood condition which has preceded treatment. II. Physical and chemical studies of human blood from cases of diabetes mellitus. *Ibid* 37, 18-31(1926); cf. *C. A.* 16, 2521; 17, 2139; 19, 2530, 3319.—In young patients hyperglucemia is attended by acidosis and increased erythrocyte vol.; in old arteriosclerotic diabetics these changes occur only in coma. The cond. chloride discrepancy of both types is present. The type with a higher cond. than that corresponding to the Cl concn. is permanent; the reverse type is transient. Most of the glucose is found in the serum, but with retreating hyperglucemia the concn. in the corpuscles may be greater on account of a lag in diffusion. The ratio of serum and corpuscle glucose is difficult to det. as it is easily upset by changes in concn. and distribution caused by insulin. The Cl concn. in the erythrocytes is not affected by their vol. increase. There is a loss of Cl in hyperglucemia, higher in the corpuscle than in the serum. In the dehydration of severe acidosis the corpuscular Cl may increase because of water transference and retention of Cl. There is no consistent relation between hyperglucemia and corpuscular Cl. M. J.

Liver injury in thyrotoxicosis as evidenced by decreased functional activity. I. B. YOUNG AND L. M. WARFIELD. *Arch. Internal Med.* 37, 1-17(1926).—Impairment of liver function was demonstrated by the usual tests in 21 out of 44 patients, decreased glucose tolerance in 21 out of 27. There was no apparent relation between liver function and any of the other features of the disease except the loss of wt. M. J.

Water metabolism. EDMUND ANDREWS. *Arch. Internal Med.* 37, 82-7(1926), cf. Fischer, *C. A.* 15, 1931.—The amt. of glucose soln. required to produce diuresis in the so-called dehydration fevers of dogs varies with the alk. reserve. Below an alkali reserve of 45 no water is excreted; above this value the water reserve which amts. to from 0 to 72 g./kg. increases about 10 cc. for each cc. of CO₂-combining power of the blood plasma. Various clinical phenomena find an explanation in the influence of the water reserve on water absorption and excretion.

MARY JACOBSEN
Glucose utilization in renal glucosuria. J. E. PAULLIN. *Arch. Internal Med.* 37, 88-91(1926).—It is concluded from the respiratory quotient and basal metabolism of a patient that metabolism and storage of carbohydrate in renal glucosuria are the same as in normal health.

MARY JACOBSEN
Blood-sugar curves in epidemic encephalitis. J. KASANIN AND G. P. GARFIELD. *Arch. Internal Med.* 37, 102-9(1926).—In 17 cases of encephalitis or postencephalitic conditions the sugar curves showed mostly deviation from normal, high curves being prevalent in adults, flat curves in children.

MARY JACOBSEN
The refractometric and viscometric indexes of cerebrospinal fluid. A. LEVINSON AND A. M. SERBY. *Arch. Internal Med.* 37, 144-50(1926).—The indexes, of which a no are given, betray only a marked increase in the protein content. Such a marked increase is usually indicative of a pathologic process of the nervous system such as meningitis, obstructive hydrocephalus and compression myelitis. Normal readings, however, do not exclude pathol. conditions. The readings do not change with the age of the fluid.

MARY JACOBSEN
The relation of albuminuria to protein requirements in nephritis. J. P. PETERS AND H. A. BULGER. *Arch. Internal Med.* 37, 153-85(1926).—Patients with acute and

chronic parenchymatous nephritis usually show evidence of previous protein deficiency which may be partly caused by faulty diet and to a large part probably by N wastage of the disease itself. "The N catabolism of these patients can be estd. from the non-protein N after proper allowance has been made for changes in blood tissue and non-protein N and variations in body weight due to diuresis and edema." Large amts. of fat and carbohydrate are able to reduce the N catabolism to from 0.5 to 0.7 g./kg. a day. N wastage may be prevented by administration of sufficient protein to cover not only the requirements of N catabolism but also the albumin loss in urine. Excess protein may be stored by patients to repair previous N deficiency. An abnormally high non-protein N in the blood occurred only in relatively high N catabolism and was restored to normal when the latter decreased.

MARY JACOBSEN

Gastric secretion in experimental beriberi in the dog. MARTHA BELLE FARNUM. *Arch. Internal Med.* 37, 212-6(1926).—The vol. and the free and total acidity of the gastric secretion of the dog and the response to *histamine*-HCl injection decreases gradually and substantially under a beriberi-producing diet. The gastric response to *gastrin* is hardly affected. The harmful effect of alkali in autoclaving food is due to the destruction of the antineuritic vitamin. The latter is not a gastric secretagog.

MARY JACOBSEN

The inorganic phosphorus and calcium of the blood in nephritis. H. W. SCHMITZ, E. L. ROHDENBURG AND V. C. MYERS. *Arch. Internal Med.* 37, 233-43(1926).—A blood serum Ca below 7 mg./100 cc. was found in relatively many cases of chronic interstitial nephritis with muscular twitchings and convulsions. No uniform reciprocal relation was found between inorg. P and Ca in different cases, although it may be observed in individual cases. As a rule high inorg. P is accompanied by low CO₂ capacity of the plasma. A few p_H detns. showed the acidosis to be of the uncompensated variety. Inorg. P retention is a reliable prognostic sign, but the creatinine is equally reliable and appears somewhat sooner.

MARY JACOBSEN

Intradermal salt solution test in cardiac diseases in children. H. C. OLMSTED. *Arch. Internal Med.* 37, 281-90(1926).—The disappearance time is shortened in the edematous regions in decompensated heart diseases, but not constantly enough to serve as a prognostic sign. In toxic cases without decompensation a shortened time of disappearance gives an unfavorable prognosis. Equal time of disappearance in life and after death was found in 2 cases, showing that circulation is not necessarily involved in the phenomenon.

MARY JACOBSEN

Excretion of phenolsulfonephthalein in obstructive jaundice. H. A. ABRAMSON. *Arch. Internal Med.* 37, 291-6(1926).—In 15 cases of uncomplicated obstructive jaundice the excretion of phenolsulfonephthalein was normal. Since the convoluted tubules are chiefly affected in jaundice, while the glomeruli are not influenced, this finding supports the view that excretion takes place through the glomeruli. Cases with an apparently normal kidney function in which jaundice causes uremia suggest the presence of a latent kidney lesion increased beyond the breaking point by the additional injury of jaundice. The mode of action of the latter is still obscure.

MARY JACOBSEN

Guanidine poisoning and the tetany of pregnancy. LUIGI DI FAZIO. *Arch. ostetr. ginecol.* 11, 337-48(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 30, 814(1925).—Gravid guinea pigs died after the smallest dose of guanidine (injected), which is possibly the cause of tetany of pregnancy. Obduction showed no difference between pregnant and non-pregnant animals.

MARY JACOBSEN

Glycolytic properties of cancer cells. N. WATERMAN. *Bull. assoc. franç. pour l'étude de cancer* 13, 396-409(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 384(1925); cf. C. A. 19, 1737.—Warburg's and Minami's results are confirmed. There is an antagonism between O consumption and glycolysis in normal as well as in cancer cells. The kidney has the highest O consumption and the lowest glycolytic power. The latter is reduced by Ca. Hexosephosphoric acid is attacked by the kidney with lactic acid formation. The presence of insulin in cancer tissue could not be ascertained. Tumor tissues often, although not constantly, yielded an ext. which, without having any glycolytic effect itself, increased the glycolytic action of the kidney.

M. J.

Influence of temperature on the production of experimental tar carcinoma in the mouse. E. DEROM. *Bull. assoc. franç. cancer* 13, 422-62(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 30, 863(1925).—Heating the tar to 70° and repeated short application of metal plates heated to 50° previous to painting with tar of 70° promoted formation of cancer. It was retarded if the temp. of the plates was 60-70°. Neither the above heat application alone nor tincture of I produced carcinoma. The malignant skin carcinomas were partly of the spindle-cell type and showed infiltrative growth and ulceration, partly metastase formation in the lymph glands.

MARY JACOBSEN

Phlorhizin glucosuria. C. ALEXANDRESCU-DERSCA, V. CIOLTEAU AND L. ADLERSBERG. *Bull. mém. soc. méd. hôp. Bucarest* 6, 147-52(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 29, 619-20.—Tests in 30 cases with intact kidneys and exactly known condition of the liver partly support Teissier's hepatic theory of phlorhizin action. Although always modified in diffuse lesions of the liver the test does not permit a prognosis. The abnormal urinary urea quotient seems to be the only reliable indication of diffuse liver lesions. Hay's test is also characteristic although not always positive in liver diseases. The urobilin content cannot serve as a diagnostic means.

MARY JACOBSEN

Inorganic metabolism in tetany. J. G. F. DE GEUS. *Dissertation*, Leiden, 1924; *Ber. ges. Physiol. exptl. Pharmacol.* 30, 895(1925).—Tetany is not caused by alkalosis as such, nor is it influenced by the PO_4 ion. It always occurs, when Ca is lower than 8 mg./100 cc.; above this Ca level it occurs only in the presence of a Na excess.

M. J.

The determination of urobilin in urine and feces and the role of the liver in urobilin secretion. J. G. F. VAN SPENGLER. *Dissertation*, Leiden, 1924; *Ber. ges. Physiol. exptl. Pharmacol.* 29, 625.—Schlesinger's method was modified. Adler's method was used for the detn. of urobilin in urine and a modification of it for the feces. *Conclusions*—The higher urobilin content of the portal blood of young calves and rabbits as compared with other areas is in favor of intestinal urobilin formation. It may, however, be also formed elsewhere. Theoretically any abnormally high urobilin content in the urine must be considered as a sign of hepatic disease or insufficiency. Normally the urobilin content of urine (I) is 3 mg./24 hrs., that of the feces (II) 100 to 150 mg., I/II never over 0.02. In hemolytic processes (pernicious anemia, hemolytic icterus) both I and II are increased and I/II often remains unchanged. The urobilinuria of cardiac obstruction and hepatic cirrhosis must also often be considered as a symptom of relative liver insufficiency.

MARY JACOBSEN

Glucolysis. P. B. VAN STEENIS. *Dissertation*, Utrecht, 1924; *Ber. ges. Physiol. exptl. Pharmacol.* 30, 910(1925).—A study of glucolysis in normal and diabetic blood *in vitro*.

MARY JACOBSEN

The action of bile and its chief components on the contraction of uterine muscle fiber. GIUSEPPE DELLEPIANE. *Folia gynaecol.* 19, 217-39(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 29, 457.—In view of the tendency of icteric women to abortion and atonic hemorrhages the effect of bile and its constituents was tested by the Magnus-Kehrer method on the surviving isolated muscle fibers of gravid and non-gravid uterus of rabbits, cats and guinea pigs. *Na glyco- and taurocholate* and *taurine* had in small doses a stimulating, in large doses a depressing, effect on the tonus and the individual contractions. *Cholesterol* and *glycocholic acid* had a depressing effect. The action of whole bile of the same as well as of another species varied greatly, apparently because of the varying proportions of the individual constituents. Large doses of bile (1.5% of the Ringer-Locke solu.) always paralyzed uterine contractions.

M. J.

Certain histological changes in the ovary as a result of lipid feeding. DOMENICO FERACCIU. *Folia gynaecol.* 19, 241-8(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 152.—Ten injections of 0.3 to 0.35 g. *cholesterol* produced in the ovaries of rabbits the same changes as placenta exts. or gravidity: increase of interstitial tissue and diminished no. of follicles.

MARY JACOBSEN

The mechanism of phlorhizin glucosuria. H. SHIOYA. *Hokkaido Igaku Zasshi* 3, 49-66(1925).—Phlorhizin does not cause hyperglucemia. Unlike normal animals, venous and arterial blood have the same glucose content. Diuresis is produced in spite of the reduced quantity of circulating blood. More sugar is excreted than is split off by the ingested phlorhizin. Phlorhizin does not influence the respiratory exchange, but it considerably increases the gas metabolism of the kidneys. This increase is apparently not a secondary effect of glucosuria or diuresis, since glucose glucosuria and ovalbumin albuminuria do not affect the metabolism of the kidneys. The conclusion is reached that the permeability of the kidneys to glucose is increased as a result of the augmented metabolism and that an unknown metabolite causes glucosuria.

M. J.

Abderhalden's reaction and its dependence on digestive enzymes. F. VENULET. *Medycyna doswiadczalna* 2, 350-7(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 29, 465.—Only the micro-Kjeldahl gives exact results. In the rabbit degradation of muscle and kidney tissue during the periodic action of the digestive glands was established. It is therefore always necessary to consider the physiol. condition of the digestive glands, especially of the pancreas. Expts. on rabbits with ligated kidney vessels demonstrated the occurrence of isolated degradation of kidney tissue.

MARY JACOBSEN

The hemolysins in the colostrum of woman. MASASHI NAKAMURA. *Mitt. med.*

Fak. Kais. Univ. Tokyo 32, 317-34(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 325.—Colostrum hemolyzes only after the addn. of complement. The hemolytic effect is subject to individual variations. It is more pronounced in early colostrum and somewhat lessened by inactivation. Addn. of hemolytic immune serum reveals the presence of a hemolytic complement, the quantity of which is also subject to individual and daily variations.

MARY JACOBSEN

The distribution of bilirubin in the various vascular areas and its relation to the pathogenesis of icterus. CARLO GAMNA AND ATTILIO OMODEI. *Pathologica* 16, 121-4 (1924); *Ber. ges. Physiol. exptl. Pharmacol.* 29, 248.—The role of the liver is by no means established. In heart diseases, in 30% of infectious diseases and in atrophic cirrhosis the bilirubinemia was more pronounced in the liver venous blood than in other areas. In the liver diseases studied (cirrhosis without icterus, CHCl_3 poisoning, acute yellow atrophy) no significant differences were observed. In chronic infectious diseases, in tumors outside the bile ducts and in endocrine disturbances bilirubinemia was often absent.

MARY JACOBSEN

The sedimentation velocity of erythrocytes and the diagnosis of latent or active tuberculosis. FILIPPO D'ASARO. *Pediatria (Riv.)* 34, 57-70(1926).—In tuberculous children in the 1st and 2nd stage, free from other infections, the sedimentation velocity is not influenced by the Pirquet test or by the subcutaneous injection of foreign protein, but changes from 5 to 30 mm. after the subcutaneous injection of 1 mg. Koch tuberculin. The degree of the increase and the rate at which the normal velocity is reestablished afford a conclusion as to the latency or impending activity of the process. M. J.

Agglutinins in the blood following typhoid vaccination in children. LUIGI AURICCHIO. *Pediatria (Riv.)* 34, 113-8(1926).—Typhoid vaccination with the therapeutic dose of Wright vaccine causes appearance of sp. agglutinins in the circulation and may therefore lead to diagnostic errors when the agglutinin reaction is used. The "lysed" serum of Caronia and Cristina and Ceutanni's stomosines do not cause this reaction.

MARY JACOBSEN

The increase of the diastatic power of urine as a diagnostic means in acute diseases of the pancreas. CARL PERMIN. *Rev. chirurg.* 43, 341-55(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 114.—In a case of pancreatic suppuration and in exptl. lesions in dogs and rabbits a marked increase in the diastatic power of the urine was observed.

MARY JACOBSEN

Cholesterol in blood and duodenal fluid during pregnancy. DOMENICO FERRACCIU. *Riv. ital. ginecol.* 3, 5-16(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 416(1925).—In normal women the mean cholesterol content of blood is 0.151% (Grigaut), that of duodenal fluid (linhorn tube) is 0.072. In 13 pregnant women in the last 3 months the former was 0.220%, the bile cholesterol 0.062%. The latter rose mostly, although not always, during the puerperium.

MARY JACOBSEN

Protein concentration in puerperal serum. II. GIOVANNI ALBANO. *Riv. ital. ginecol.* 3, 35-63(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 438(1925).—In 81 pregnant women the protein content (n) of the blood serum, esp. of retroplacental blood, was found to be lowered. It rose during delivery and returned to normal rapidly during the puerperium. The serum protein of fetus and newborn is much lower than the maternal. Anemias have the same effect, while extragenital tuberculosis causes a rise in serum proteins. Syphilis has no effect.

MARY JACOBSEN

Lipolytic enzymes in the serum of pregnant women. FIORENZO CLAUSER. *Riv. ital. ginecol.* 3, 83-105(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 436(1925).—The lipase is strongly reduced in content, but more resistant to atoxyl than that of normal serum. This suggests diffusion of considerable quantities of liver lipase into the blood. The presence of kidney lipase is excluded by its sensitiveness to poisons, that of placental lipase by its selective action on various substrates. No conclusion is afforded as to a possible liver injury, since no liver lipase was found in the serum in a case of eclampsia. The reduced lipolytic power may be caused by hypercholesterolemia.

MARY JACOBSEN

Experimental production of Röntgen carcinoma in the rabbit. General remarks on the origin of experimental carcinoma. BR. BLOCH. *Schweiz. med. Wochschr.* 54, 857-65(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 859(1925).—B. succeeded in producing a true, malignant metastasizing carcinoma on the ear of the rabbit by frequent irradiations over a long period of time.

MARY JACOBSEN

Local acidosis in primarily healing wounds. S. GIRGOLAFF. *Z. Chirurg.* 51, 2297-300(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 30, 30.—The p_H in noninfected, primarily healing wounds is lower than in normal tissue. The min. 6.32 is reached in 24 hrs.

MARY JACOBSEN

Indicanuria as a symptom of fistula gastrocolica. HERMANN STEINITZ. *Arch. Verdauungs-krankh.* 36, 29-33(1926).—Discussion. FRANCES KRASNOW

The occurrence of paralysis after treatment with antirabic vaccine. J. W. CORNWALL AND W. A. BEER. *Indian J. Med. Research* 13, 67-74(1926).—"The fresh normal nerve substance is toxic to both rabbits and men when injected subcutaneously. The toxic dose varies widely with the individual, some showing paralysis after less than 20 mg. per kg. body wt., others tolerating over 1 g. per kg. without inconvenience. The action of the phenol renders the nerve substance slightly less toxic. In antirabic treatment it is desirable to be able to increase the dose of the antigen. This could be done either by sepg. the antigen from its toxic vehicle (nerve tissue) or by neutralizing the toxicity of the vehicle. The latter alternative seems the more practicable." F. K.

The rate of multiplication of rabies fixed-virus in rabbits. J. W. CORNWALL AND W. A. BEER. *Indian J. Med. Research* 13, 475-82(1926).—"The strain of fixed-virus in use at the Pasteur Inst. Coonoor is in its 940th passage. If this virus be subpassaged in rabbits, each subpassage animal being killed on the 3rd day, the series cannot be continued beyond the 2nd subpassage. If each subpassage animal be killed on the 4th day or later, the series can be continued indefinitely with no increase in the length of the incubation period. The rabies fixed-virus, therefore, does not multiply at such a rate that 0.01 g. of brain substance can carry a lethal dose of it after 2 subpassages performed on the 3rd day, but 0.01 g. will always contain a lethal dose if the subpassages be made on the 4th day or later." FRANCES KRASNOW

Relation between different modes of sterilization of vaccine and protective power. K. R. K. IYENGAR. *Indian J. Med. Research* 13, 547-54(1926).—"Vaccines sterilized by heat at 40° and 60° for 1/2 hr. with subsequent addn. of 0.5% carbolic acid protected as efficiently as the vaccines sterilized by carbolic acid only. The no. of survivals were 26 out of 40 pigeons prophylactically treated with each of the vaccines. Vaccines heated at 80° for 1/2 hr. with subsequent addn. of 0.5% carbolic acid showed considerable loss of protective power. The no. of survivals were 8 out of 40 pigeons prophylactically treated. There is no direct correlation between agglutinins and protection." FRANCES KRASNOW

Anthrax aggressin. C. F. SALSBERY. *J. Am. Vet. Med. Assoc.* 68, 755-72(1926). Aggressin produces active immunity. Anti-aggressive serum may be produced by the gradual immunization with aggressins. This antiaggressive immunity may be passively transferred. FRANCES KRASNOW

The nature of the change of the blood in syphilis and its demonstration by means of alcoholic extracts of the spirochetes. F. KLOPSTOCK. *Deut. med. Wochschr.* 52, 226-9(1926).—Alc. exts. of the spirochetes of syphilis gave high sp. complement-fixation reactions with syphilitic sera; they paralleled the Wassermann test but were more sensitive. Aq. exts. with lecithin added were much less reliable as antigen. No useful results were obtained with exts. freed from their lipid content, for which lecithin was substituted. The various methods tried in prepg. the ext. are discussed. Exts. of *Spirocheta dentium* gave equally as good antigen as the *Treponema pallidum*. Injection of rabbits with suspensions of heat-killed spirochetes led to a rapid development of antibodies that reacted both with the Wassermann antigen and the alc. spirochetal exts. The latter antigen has the advantage of not reacting with normal rabbit serum in complement fixation. The Wassermann reaction is considered to be a true immune reaction, being an extension of antibody formation from spirochetal lipoids to organ lipoids. LOUIS LEITER

Total acid-base equilibrium of plasma in health and disease. VII. Factors causing acidosis in chronic nephritis. H. A. BULGER, J. P. PETERS, A. J. EISENMANN AND C. LEE. *J. Clin. Invest.* 2, 213-26(1926).—"The acidosis of chronic nephritis is caused chiefly by a reduction of total base and an increase of undetd. acids, phosphate being less important. Low plasma chloride helps to prevent reduction of plasma bicarbonate and counteracts acidosis. LOUIS LEITER

The excretion of ammonia and titratable acid in nephritis. D. D. VAN SLAKE, G. C. LINDER, A. HILLER, L. LEITER AND J. F. MCINTOSH. *J. Clin. Invest.* 2, 255-88(1926).—"In 11 normal subjects the NH_4 /acid ratio averaged between 1.0 and 2.0, with considerable variation from the mean. The mean ratios were 1.0-2.9 in nephrosis (6 cases), 0.8-1.6 in benign nephrosclerosis (5 cases), 0.6-1.5 in acute glomerulonephritis (8 cases), 0.4-0.9 in mild cases of chronic glomerulonephritis and below 0.5 in cases of chronic glomerulonephritis and malignant nephrosclerosis where renal function was considerably impaired. The ratio in the last group showed fixation as contrasted with normal variability. The low ratios were due to diminished NH_4 excretion. The danger of acidosis is increased when acid-producing diuretics are used in patients with a

diminished NH_3 excretion. Blood NH_3 N varied between 0 and 0.09 mg. per 100 cc. in nephritic patients, including the terminal stages, indicating no retention of NH_3 in the blood. The NH_3 /acid ratio does not regularly parallel the urea concg. power.

LOUIS LEITER

Antigenic properties of certain glucoproteins. KENNETH GOODNER. *J. Infectious Diseases* 37, 285-90(1925).—Glucoproteins from beef submaxillary glands, hog stomach linings, beef nasal septums, beef tendons and egg-white (ovomucoid and ovoglobulin) were compared by means of the precipitin test as to their immunological relationship. Although these substances proved to be poor antigens as far as the production of precipitins is concerned, results are presented to show that there is no antigenic action in common with each other or with serum (beef) except with ovomucoid and ovoglobulin which do show a certain amt. of relationship.

JULIAN H. LEWIS

Toxic products of Bacterium enteritidis and of related microorganisms. SARAH E. BRANHAM. *J. Infectious Diseases* 37, 291-308(1925).—These expts. were designed to det. the nature of the substance responsible for the toxic action of the filtrate of cultures of organisms of the paratyphoid group, with *B. enteritidis* as a representative. These filtrates are toxic for rabbits and mice, but not for guinea pigs, when injected intravenously but are apparently harmless when given by other routes. Symptoms appear within 40 to 45 min. and last from $\frac{1}{2}$ to 1 hr. after which there is death or slow recovery. Toxicity of the cultures appears after the no. of living cells has reached its max. and has begun to decrease. The toxic properties are demonstrable not only in filtrates of fluid cultures, but in autolysates, and with dead and living cells. The results appear to indicate the poison demonstrated in these expts. is within the bacterial cells, is set free on cell disintegration and is thermostable, although it is able to produce an antiserum in rabbits when injected in dilns. in which no protein could be demonstrated.

JULIAN H. LEWIS

The protective substance in antipneumococcus serum. II. Effect of certain chemical manipulations on the stability of the protective substance in Type 1 antipneumococcus serum. L. D. FELTON. *J. Infectious Diseases* 37, 309-20(1925).—The protective H_2O -insol. globulin contained in type 1 antipneumococcus serum loses its protective power when the process of dissolving in NaCl and pptg. by diln. in H_2O in alternation is often repeated. There is a loss in N content of the pptd. globulin and this bears some relation to the loss in protective power. There is an almost complete loss of P, but as the P-free globulin has some protective power it is assumed that the protective substance has no or an extremely small P content. When the protective globulin is dissolved and repptd., resp., by dil. HCl and by NaOH it maintains its protective power for at least 10 pptns. provided it does not become insol. in neutral salts. Fractional pptn. at various H-ion concns. in HCl-NaOH mixts. yields variable results, probably due in part to long-continued shaking at room temp., but in the main the greater part of the protective substance is pptd. at a H-ion concn. of between p_{H} 6 and 7.

JULIAN H. LEWIS

Quantitative relations between antigen and antibody in the precipitin reaction. H. W. CROMWELL. *J. Infectious Diseases* 37, 321-8(1925).—When 2 or more sp. pptg. serums are tested against the same lot of antigen, they all react with the same diln. of the antigen regardless of the strength of the serums, provided a simple antigen is used. The detn. of the point of disappearance of a recognizable ppt. on increasing the diln. of the antigen does not, therefore, give direct evidence as to the strength of the antiserum. The point of max. pptn. when a single diln. of the antiserum is tested against the various antigen dilns. represents an approx. equal no. of units of antigen and antibody. On the basis of this fact one can calc. the antibody content of the serum with considerable accuracy when, by test, the antigen titer and point of max. pptn. have been detd. with 1 diln. of the serum. These exact quant. relations do not obtain when a complex antigen-like serum is used. The antigen titer is not const. but varies in a general way with the antibody titer of the serum. The max. ppt. occupies a whole zone in which it is often impossible to pick out 1 tube showing heavier flocculation than the others. It is not possible, therefore, to make calcs. that would agree even approx. with exptl. results. The neutralization of antigen by its sp. antibody in the precipitin reaction seems, like the toxin-antitoxin reaction, to follow the law of multiple proportion. J. H. L.

Standardization of tuberculin. Assay on the basis of the spermatocyte reaction. E. R. LONG. *J. Infectious Diseases* 37, 368-84(1925).—A review of the literature points out the unsatisfactory features of the heretofore used methods for standardization of tuberculin which can be grouped under 2 heads, those based on the interaction of tuberculin and serum antibodies in the serum of tuberculous animals and those based on the action of tuberculin on the hypersensitive tuberculous animal. L. proposes a new

method based on his observations of the spermatocidal action of tuberculin when injected into the testicles of tuberculous guinea pigs. The chief advantages of this method are the abs. specificity of the reaction, the great delicacy of the reaction, the sharp picture presented by the positive reaction, the constancy of the reaction (as compared, *e. g.*, with the variable skin reaction), and the ease with which a permanent record of the reaction may be preserved. The chief disadvantages are the length of time desirable before reading the reaction (3-4 weeks) and the necessity of cutting, staining and examining the section.

JULIAN H. LEWIS

Relationship of enteritidis-paratyphoid B infections to hyperglucemia in rabbits. MAUD L. MENTEN AND HELEN M. MANNING. *J. Infectious Diseases* 37, 400-10(1925)

Rabbits subjected to adverse environmental conditions develop hyperglucemia. Coincident with a marked hyperglucemia, cultures of organisms of the enteritidis-paratyphoid B group may be recovered from organs of rabbits, which likewise show characteristic morphologic changes. Similar pathologic conditions can be produced by the injection of killed or living organisms of this group. When the hyperglucemia is of long standing hydropic degeneration of the islets of Langerhans is present.

JULIAN H. LEWIS

Effects of diphtheria toxin on the myocardium of guinea pigs. C. W. APPELBACH. *J. Infectious Diseases* 37, 443-8(1925).—The changes in the myocardium of guinea pigs after injection of diphtheria toxin subcutaneously resemble the changes described in the myocardium in human diphtheria, but they are in general not as extensive. By direct injection of the myocardium, extensive degenerative and inflammatory changes can be produced in the guinea pig equal in intensity to those found in human diphtheria. The outstanding changes are retrogressive (cloudy, swelling, fatty change and necrosis). Infiltration of leucocytes with degenerative changes occur, but in the myocardium of guinea pigs degeneration, proliferation and exudation were not commonly observed together in the same regions. The degenerative changes in the skeletal muscles, liver and kidneys, as represented by the amt. of fat that can be stained with Sudan III, are less than those in the myocardium.

JULIAN H. LEWIS

The isolation of substances with immune properties. ARTHUR LOCKE AND E. F. HIRSCH. *J. Infectious Diseases* 37, 449-64(1925).—A method is given for the prepn of a highly purified hemolysin. Hemolysin is sepd. from amboceptor serum by selective absorption on homologous erythrocytes. It is recovered through a destruction of the combining capacity of the erythrocyte for the bound hemolysin. This is accomplished by means of ether extn. This procedure permits hemolysin to be obtained in good yield and of a purity such that but 0.000,125 to 0.000,18 mg. of protein are associated with each hemolytic unit. It is demonstrated that the failure of certain reported preps. of hemolysin to give a positive chem. test for the presence of protein is due to the lack of a sufficient delicacy in the tests employed. Qual. tests are proposed which, under restricted conditions, permit the detection of protein in concns. as low as 0.006 to 0.035 mg. per cc. The stroma-hemolysin combination is loosened and made easily dissociable when the lipins of the stroma are partially removed by ether extn. This behavior is correlated with the shifting of the isoelec. point of the stroma from p_H 5 to p_H 7, approx., when the lipins are so removed. It is suggested that while lipin free stroma protein may be antigenic in the production of hemagglutinin, the antigenic entity in the production of hemolysin is probably the entire lipoprotein complex. When erythrocytes are added to an homologous immune serum, the hemolysin of the serum becomes redistributed between the added cells and some component of the serum. This component is not present in normal serum. It is probably derived from the disintegration of the erythrocytes used in immunization. It is suggested that the appearance of antibodies in the blood plasma follows the disintegration, by lysis and phagocytosis, of antigen already satd. with antibody by a primary process.

J. H. LEWIS

Studies on respiratory diseases. XXI. Electrophoretic potential and virulence of pneumococci (Types 1, 2, 3, and 4). I. S. FALK, H. A. GUSSIN AND M. A. JACOBSON. *J. Infectious Diseases* 37, 481-94(1925).—A specially constructed app. was used to measure the electrophoretic potential of 76 strains of the 4 types of pneumococci isolated from cases of lobar pneumonia. The results of the measurements are expressed in electrophoretic velocities (μ /sec.) of the migrating bacteria. These velocities can be converted into potentials in millivolts by multiplying by 1.3. It appears that the electrophoretic potentials are different from the several types, the highest being 11 μ /sec., uniformly found on type 3 organisms which is 2 or 3 times as high as those found on organisms of the other types. The potentials on types 1, 2 and 4 are not as sharply marked off as those on type 3. The most probable sequence of decreasing potential is types 3, 1, 2, 4. The sequence of decreasing virulence of these organisms is identical with the sequence of decreasing electrophoretic potential. This finding is discussed.

especially in the light of anticipations that this would be found, anticipations based on the commonly found parallelisms (direct or inverse) between virulence, agglutinability and other characteristics of bacteria and on considerations of the role of the electrophoretic potential in the phenomenon of agglutination. **XXII. Some relations between fatality in lobar pneumonia and electrophoretic potentials on pneumococci.** I. S. FALK, M. A. JACOBSON AND H. A. GUSSIN. *Ibid* 495 8.—Just as the sequence of decreasing virulence is the same as the sequence of decreasing electrophoretic virulence (types 3, 1, 2 and 4) so is also the sequence of decreasing fatality rate in lobar pneumonia with these organisms. As was anticipated, organisms from fatal cases of pneumonia show larger potentials than organisms from non-fatal cases, a fact which might be used to determine the prognosis in lobar pneumonia. **XXIII. Electrophoretic potential and virulence of variants of type 1 pneumococci.** *Ibid* 499–506.—The electrophoretic potentials of 2 variant strains (B and C) derived from a parent strain of type 1 pneumococcus (A) parallel the virulence of these organisms, the sequence of decreasing virulence as well as for decreasing potential being strains A, B, C. An addendum gives the measurements of the relative viscosities of the cultures of pneumococci A, B and C in order to determine whether or not the velocities which are given in the tables and which are treated as linear functions of electrophoretic potentials are due to different alterations in viscosity produced by the different strains. The values found are practically identical and indicate that viscosity variations do not explain the electrophoretic potential differences. **XXIV. Electrophoretic potential, virulence and serum agglutination with single cell cultures of variants of type 1 pneumococci.** I. S. FALK AND M. A. JACOBSON *Ibid* 507–13.—Of a total of 15 single cell strains isolated from Blake and Trask's A, B and C cultures of pneumococci (A = type 1; B and C are variant strains obtained from A by growth in the presence of homologous antiserum) one (A1) showed evidences of contamination. Expts. with the remaining 14 (5 from A, 5 from B, 4 from C) and with the parent strains demonstrate that each of the single cell strains is indistinguishable from the parent strain from which it was derived with respect to electrophoretic potential, virulence for white mice and serum agglutination. The parent strains have been carried in stock on blood agar slants through a large no. of generations and up to the present time there have been no evidences of spontaneous changes or in the single cell strains. So far as concerns the characteristics studied, each breeds true. **XXV. The influence of certain electrolytes and nonelectrolytes on the bile solubility of pneumococci.** I. S. FALK AND S. Y. YANG. *Ibid* 38, 1–7 (1926).—An analysis of the mechanism of the action of bile on pneumococci is made. As pneumococci washed with H_2O are no longer sol. in bile a study of the influence of salts on their soly. was made. Chlorides with monovalent cations (Na, K, NH_4 , Li) in relatively low concns. inhibit soln. of washed pneumococci in bile. In higher concns. these chlorides do not inhibit and may accelerate the dissolution of the bacteria. Chlorides with bivalent cations (Ca, Ba) behave differently. They inhibit bile soln. of pneumococci more effectively in high than in low concns. Of the anion series tested, NaOH and Na_3PO_4 are cytolytic to pneumococci; Na_2HPO_4 , NaH_2PO_4 , Na_2SO_4 and $NaNO_3$ are not cytolytic. Cytolysis by NaOH and Na_3PO_4 appears to be a function of OH-ion concn. Peptone, gelatin and ovalbumin appear to inhibit cytotoxicity by bile in the same manner as $CaCl_2$ and $BaCl_2$. The inhibitory action increases with concn. **XXVI. The lysis of pneumococci by sodium oleate.** *Ibid* 8–13. Since bile is a substance of complex and inconstant composition a more simple compd. was tested which has the property of lowering surface tension. As Na oleate has been previously used for differentiating pneumococci its action was compared with that of bile. In concns. of 1.25% and higher, pure solns. of Na oleate in H_2O are bacteriolytic to washed suspensions of pneumococci of types 1, 2 and 3. It dissolves pneumococci only of those strains which are dissolved by bile. NaCl soln. and broth culture fluid inhibit bacteriolysis of pneumococci by Na oleate and by bile. Saponin in concns. up to 10% do not dissolve pneumococci. The bacteriolysis of pneumococci by NaOH, Na_3PO_4 (reported above) and Na oleate is as sp. as bile soly., in that they do not dissolve bile-insol. pneumococci and other strains of bacteria. **XXVII. Electrophoretic potential, acid and serum agglutination of pneumococci.** I. S. FALK AND M. A. JACOBSON. *Ibid* 182–7.—For pneumococci, as has already been found for other bacteria, with increasing acidity the p. d. between bacteria and menstruum declines from negative values to an isoelec. point, then to an increasing positive value and, near p_H 0, to a 2nd isopotential point. The isoelec. points of the pneumococci of types 1, 2, 3 and 4 and of variants (B and C) of type 1 (A) are near p_H 3 and are not significantly type sp. The p. d. for pneumococci is correlated with the inagglutinability by acid. In general, it is found that the higher the p. d. at p_H 6.5, the lower the p_H necessary to cause spontaneous agglutination. The p. d. values for the variant types can be changed relatively by wash-

ing the bacteria. An inversion of the relative potentials on variants A, B and C accompanied by an inversion in their agglutinability by acid. Type-sp., homologous and heterologous antipneumococcus serum reduces the negative p. d.; the greater effectiveness of the homologous serum in this regard parallels its greater effectiveness in agglutinating the bacteria. The correlation between potential and inagglutinability is further evidenced by the inversion of the relative stability of suspensions (A, B, C) when tested with agglutinating serum after they have been washed sufficiently to invert the relative magnitudes of the potentials. Studies on respiratory diseases. XXVIII. The electrophoretic potentials, the dissolution and the serum agglutination of pneumococci in the presence of sodium oleate. *Ibid* 188-92.—Bile is practically without effect on electrophoretic potential. Na oleate effects significant increases in the potentials on pneumococci. From this finding it was anticipated that Na oleate would increase the stability of pneumococcus suspensions and would reduce the titers for serum agglutinations. These anticipations were confirmed by expt. These results provide a further confirmation of the view that the agglutinability of pneumococci is correlated with the electrophoretic potential. The finding that the variant strains of pneumococci (A, B and C) which show marked differences in virulence for mice are equally sol. in bile or Na oleate soln. is contradictory to the usual statement that virulence and soly. are parallel characteristics.

JULIAN H. LEWIS

The effect of hydrogen-ion concentration on certain antigenic properties of *Clostridium botulinum*. I. S. FALK AND F. POWDERMAKER. *J. Infectious Diseases* 37, 514-9(1925).—The antigenic properties of a pure protein can be modified by effecting reversible changes in such of its physicochem. properties as are functions of the p_H of the protein solns. (C. A. 7, 3712). The present paper attempts to extend these observations to *Cl. botulinum* as an antigen. The addn. of acid (to p_H 2) or of alkali (to p_H 10) to a suspension of these organisms before injection into rabbits or the sep. injection into the peritoneal cavity of an equiv. quantity of acid or alkali causes an increase in the agglutinating titer of an anti-A serum for type A organisms, a reduction in the titer of an anti-B serum for type B organisms and a reduction in the titer of an anti-A or an anti-B serum for the heterologous type of organism.

JULIAN H. LEWIS

Detoxication of bacterial vaccines by formaldehyde. W. B. WHERRY AND J. A. BOWEN. *J. Infectious Diseases* 37, 520-2(1925).—The treatment of *B. dysenteriae*, Shiga and typhoid bacilli for 1 week with solns. contg. 0.04% CH_2O detoxicates the organisms without affecting their antigenic properties.

JULIAN H. LEWIS

Separation of a soluble specific substance from hemolytic streptococci. E. F. HIRSCH. *J. Infectious Diseases* 37, 523-7(1925).—A sol. sp. substance was extd. from hemolytic streptococci with dil. alkali. The chem. reactions of this substance, apparently a nucleoprotein, resembled those of similar substances prepd. from many bacteria by other investigators. Solns. of this substance give precipitin reaction in high diln. with antistreptococcus serums, and with the serum of rabbits injected with the substance.

JULIAN H. LEWIS

Nature of the toxic substances produced by *Bacillus suispestifer*. E. E. ECKER AND M. L. RICHARDSON. *J. Infectious Diseases* 37, 538-45(1925).—Young culture of *B. suispestifer* grown in 2% Witte peptone broth p_H 7, on solid media, and in a simple synthetic medium, produce a poison of unknown nature, which upon intravenous injection into rabbits causes a characteristic series of acute changes after a definite incubation period of at least 40 min. This substance appears to have some antigenic properties, but comparatively large doses of immune serum (5 cc.) are necessary to afford protection to rabbits. When the serum is given immediately (in 10-15 min.) prior to the dose of the poison itself, protection is afforded.

JULIAN H. LEWIS

Production of toxic substances in young cultures of single cell strains of *B. paratyphosus* B. E. E. ECKER AND EMERSON MAGRAIL. *J. Infectious Diseases* 37, 545-8(1925).—It was previously shown that filtrates of young cultures of *B. paratyphosus* were inconstant in their toxicity. The present expts. show that filtrates of young single cell cultures of *B. paratyphosus* B were just as toxic as the original parent cultures, but that boiling for 3 min. did not reduce the toxicity of the single cell cultures but did reduce the toxicity of the original cultures. No differences in cultural characteristics were noted between the single cell and parent strains.

JULIAN H. LEWIS

Antibody response to large and small doses of multiple and of single antigens, and restimulation of specific antibody formation by heterologous antigens. MARION CORRIGAN. *J. Infectious Diseases* 37, 549-58(1925).—A review of the literature disclosed a disagreement as to the most effective method for inducing the highest titer with bacterial antigens. The present expts. show that polyvalent bacillary antigens in large or in small doses induced practically as high an agglutinin titer for each of their

constituent organisms as did monovalent bacillary antigens. Polyvalent streptococcic antigens produced a lower titer than did monovalent streptococcic antigens. It was observed that small doses of polyvalent streptococcic antigen were more effective than large doses in the production of agglutinins. The reinjection into formerly immunized animals retaining no antibodies in the blood caused a slight recurrence of antibodies for the original antigen accompanied by a normal production of antibodies for the bacteria used in the reinjection. The recurrence of antibodies seemed to be independent of the variety of bacteria subsequently injected. The results of the reinjection into animals retaining antibodies in the blood varied. Reinjection in some cases caused a rise in the titer of the original antibodies, and on 1 occasion did not hinder the normal decreases of the original antibodies. Again, the reformation of the original antibodies did not depend on the variety of bacteria subsequently injected. The titer of the antibodies for the organism used in reinjection was comparable to that induced by injection into normal rabbits.

JULIAN H. LEWIS

An atypical Weil-Felix reaction. RUTH GILBERT AND MARION COLEMAN. *J. Infectious Diseases* 37, 559-62(1925).—A case is described in which no definite diagnosis was made, the following diseases being, in turn, considered and rejected: grippe, typhoid, Brill's disease, tick-bite fever, Rocky Mountain fever. Both before and after inactivation by heating at 62° the patient's serum agglutinated *B. proteus* × 19 in dilns. up to 1:1600, whereas serum from cases known to be typhus fever lost the agglutinins for *B. proteus* × 19 at a point between 54° and 56°. In immune rabbit serum the agglutinins were not destroyed until between 70° and 75° was reached. These results indicate the desirability of detg. the relative thermostability of the agglutinins in serum from suspected cases of typhus fever.

JULIAN H. LEWIS

Further studies on a diplococcus from measles. Prevention of measles by immune goat serum. RUTH TUNNICLIFF AND A. L. HOYNE. *J. Infectious Diseases* 38, 48-53 (1926).—As a further step in studying the etiologic significance of the organisms isolated from measles by Tunncliffe (*J. Infectious Diseases* 37, 193(1925)) the production of an immune serum was attempted. The goat was used in order to prevent in children sensitization to horse serum, and because of the reported nontoxicity of goat serum. Immune goat serum obtained by injecting the living green-producing measles diplococcus protected rabbits against a subsequent injection of infective material from measles. The rabbits injected with normal goat serum and those untreated showed some or all of the characteristics of measles in rabbits, *i. e.*, a rise of temp., Koplik spots and an eruption. Immune goat serum protected human beings against measles as effectively as convalescent human measles serum when injected on the 1st and 2nd days after exposure to measles. By intracutaneous tests in normal rabbits, the serum of goats injected with diplococci from measles, as well as convalescent human measles serum, were shown to neutralize the action of killed measles diplococci, while serum of normal goats had no such effect. The serum of 1 immune goat was found toxic to nearly all persons injected with it, but after 8 months preservation it appears to have lost its toxic effect. While these expts. do not furnish conclusive evidence of the protective value of immune goat serum, they warrant further investigation.

JULIAN H. LEWIS

Biologic significance of the soluble specific substances of pneumococci. L. D. FELTON AND G. HOWARD BAILEY. *J. Infectious Diseases* 38, 131-44(1926).—The sol. sp. substance from type 2 pneumococci when injected in extremely small doses along with attenuated type organisms produces an antagonistic effect on the defense of the animals, or an actual increase in the virulence of the microorganisms from 10 to 100 fold. The sp. sol. substance has no toxic action of itself. It is able also to neutralize both *in vivo* and *in vitro* the protective substance of antipneumococcus serum. It seems probable that this substance is similar or the same as the so-called "aggressin" and "virulin" of other authors.

JULIAN H. LEWIS

The specific precipitates obtained from antipneumococcus serum and antibody titration by the soluble specific substances of pneumococci. L. D. FELTON AND G.

...sol. in 3% NaCl, and very sol. in dil. acid and alkali when the salt content is low. The H-ion concn. of min. soly. of the 1 sample tested was p_H 6.6. Assuming that the protein of the protective substance has the p_H mol. wt. as pseudoglobulin, the combining ratio per wt. of sol. sp. substance to protein is 1:15, the mol. wt. of the sol. sp. substance being of the order of 5300 and the total mol. wt. of the resulting combination 85,300. Na_2CO_3 in concn. of 0.01 *M* is the best of the dissociating agents used. Dissocn. takes place readily in dil. acid and alkali solns. (HCl and NaOH) as judged by the free sol. sp. sub-

stance, but the resulting solns. have no demonstrable protective value. If, however, to the acid soln. is added NaCl to make 25% satn., a ppt. is thrown down contg. the protective substance. Also when a sample of ppt. is dissociated by heat in the presence of Na_2CO_3 , Na_2HPO_4 , saccharose, or NaCl, and to the clear soln. Na_2SO_4 is added to make 18% practically all the protective substance is pptd. However, this fraction insol. in 18% Na_2SO_4 still contains a small quantity of material antagonistic to defense, as well as highly protective substance.

JULIAN H. LEWIS

Influence of some anaerobic species on toxin of *Cl. botulinum* with special reference to *Cl. sporogenes*. G. M. DACK. *J. Infectious Diseases* 38, 165-73 (1926).—The filtered toxin of *Cl. botulinum* added to beef heart medium is gradually destroyed by the growth of *Cl. sporogenes* in it. The power to destroy botulinum toxin is also possessed by several other anaerobic species with proteolytic and nonproteolytic properties. The destruction of the toxin is not due to changes in H-ion concn. *Cl. botulinum* type A grew scantily in a filtrate of *Cl. sporogenes*. Growth was more vigorous in a filtrate which had been boiled but still was invisible macroscopically. Toxin was demonstrated in all the tubes but was stronger in the tubes contg. the filtrate which had been heated. *Cl. botulinum* type B did not grow in the unheated *sporogenes* filtrate nor did it produce toxin. No reduction in potency of the toxin of *Cl. botulinum* type A was noted when an equal amt of *sporogenes* filtrate was added to it. No visible growth (macroscopically) of *Cl. sporogenes* occurred in a filtrate of *Cl. botulinum* after 7 days incubation at 37°.

JULIAN H. LEWIS

Behavior of botulinum toxin in the alimentary tract of rats and guinea pigs. G. M. DACK. *J. Infectious Diseases* 38, 174-81 (1926).—Botulinum toxin when mixed with stomach tissue and abdominal wall tissue from guinea pigs and mice *in vitro* and incubated at 35° for 1 hr. was not reduced in potency except in 2 cases in which mouse stomachs were used. The reduction, however, was slight in these cases. Botulinum toxin was not completely destroyed in the stomachs and small intestines of rats and guinea pigs receiving injections of the toxin directly into the stomach. Its presence was definitely demonstrated after 12 hrs. in guinea pigs and after 3 hrs. in rats. In 2 cases out of 7 toxin was demonstrated in the blood of guinea pigs fed with botulinum toxin. No toxin was found in the blood of rats fed with large doses of botulinum toxin. Toxin was found in the blood of rats and guinea pigs 3 hrs. after intravenous injections and intraportal injections of the toxin. These expts. do not disclose the cause of the difference between rats, guinea pigs and mice in their susceptibility to botulinum toxin given orally.

JULIAN H. LEWIS

Edema as a problem in physiological regulation. F. C. McLEAN. *Physiol. Rev.* 5, 618-40 (1925).—Review. Edema is not an entity of itself, but a symptom. The fundamental problem is that of physiol. regulation of the vol. of the internal environment, including the blood and tissue fluids.

E. R. LONG

Antibodies which load microorganisms with blood platelets (thrombocyto-barins). I. L. KRICHEVSKII AND R. S. CHERIKOVER. *Z. Immunitats.* 42, 131-49 (1925).—The blood platelets of the immune animal serve as an indicator of the presence of thrombocyto-barins in the blood. These play only a passive role and can be replaced by the blood platelets of a normal horse. Serum obtained from ordinary blood coagulation contains none. Thrombocyto-barins are thermostable. After $\frac{1}{2}$ hr. at 56° serum loses its capacity to induce the loading phenomenon, but on adding to the inactivated serum the serum or plasma of a normal mouse or guinea pig, the inactivated serum is able to incite the loading phenomenon. Thrombocyto-barins are adsorbed by the corresponding antigen, with the fixation of complement. The fact that only the platelets out of all the formed elements of the blood are concerned in this reaction, speaks for the independent origin of the platelets.

E. R. LONG

Further investigation of thrombocyto-barins. I. L. KRICHEVSKII AND R. S. CHERIKOVER. *Z. Immunitats.* 45, 530-44 (1926); cf. preceding abstract.—Thrombocyto-barins result not only from infection but also from immunization of the organism artificially. Thrombocyto-barins are not identical with the lysins, and probably not with other antibodies.

E. R. LONG

Animal calorimetry. XXX. The metabolism of glycerol in phlorhizin diabetes. W. H. CHAMBERS AND H. J. DEUEL, JR. *J. Biol. Chem.* 65, 21-9 (1925); cf. C. A. 19, 3534.—A complete conversion of glycerol to glucose may occur in phlorhizinized dogs but there is sometimes a difference in individual animals. There is no general oxidation of the ingested glycerol or of the glucose into which it is converted and the observed reduction in the respiratory quotient from 0.703 to 0.678 may be exactly accounted for by the oxidation of the 2 H atoms liberated in the reaction of glycerol $\rightarrow \frac{1}{2}$ glucose

The action of glycerol in rate of excretion and the sparing of protein metabolism are similar to those of the monosaccharides.

A. P. LOTHROP

The fate of invertase in normal and immune organisms. A. SAMISSLOV. *Biochem. Z.* **164**, 110-6(1925).—When invertase is injected into normal rabbits or into animals previously immunized to yeast autolyzate, it disappears from the blood stream. The rate of its disappearance has been studied during the entire immunization process. Mixed with blood from normal or immunized animals *in vitro* the activity of invertase diminishes very slightly even after 6 hrs. It was also found that the intravenously injected invertase is not adsorbed by the blood cells. However, the invertase disappearing from the blood can be found in the organs of the exptl. animals. In immunized rabbits the liver adsorbs 50-60% of the enzyme injected, whereas in non-immunized animals only 20-30% is adsorbed. The disappearance of the invertase is that not due to an actual destruction. It is suggested that the site of greatest antibody formation is also the place of greatest adsorption of antigen.

S. MORGULIS

The precipitin reaction in the study of animal relationships. ALAN A. BOYDEN. *Biol. Bull. Marine Biol. Lab.* **50**, 73-105(1926).—The titer of an antiserum is directly proportional to the concn. of antigen within its limits of reaction. Total N detns. should be made on all antigens in order to obtain comparable results. The specificity of the reaction of an antiserum decreases with time. The H-ion concn. of antigen solns. affects the reaction, therefore buffered salt solns. should be used. Increase of salt concn. from 0.85 to 2.25% decreases the titer of chicken antisera and tends to increase their specificity. Filtration of antisera through Berkfeld filters usually does not decrease the titer nor change the specificity. There is a variation in response of different animals of the same species to the same protein. There was a general agreement in the group reactions obtained in the majority of cases. This correspondence was independent of the strength of the antisera used and occurred in antisera produced in such different animals as rabbits and fowls. There is an inhibition of the response of rabbit antisera to other rodent bloods which is absent in the fowl. The principle of reciprocal relationships can be used to test the agreement of the values obtained. The ring test is quant. sp. for no heterologous reaction ever exceeded the homologous reactions of the same antiserum. The ring test when properly performed may give information of value to the student of animal relationships.

L. W. RIGGS

Pollen therapy with protein-free extracts. J. H. BLACK AND MARGARET C. MOORE. *J. Am. Med. Assoc.* **86**, 324-5(1926).—The results of treatment of ragweed-sensitive persons with a ragweed ext. contg. no protein justify the statement that the active substance in pollen is not protein in character.

L. W. RIGGS

The sedimentation velocity of the red blood corpuscles in leprosy. H. P. LIE. *Medicinsk Revue* **42**, 133-50(1925).—Lie has examd. the blood in 33 patients suffering from various forms of leprosy by means of the method and app. described by A. Westergreen (Die Senkungsreaktion, *Ergebnisse der inneren Medizin und Kinderheilkunde*, **26**). The results differ widely, but when due regard is taken of the clinical symptoms and the phase of development of the disease a certain correspondence may be seen, and the method may be a valuable aid in judging the momentary state of each case.

C. A. ROBAK

The glycolysis of bacilli-containing rat tumors and normal rat tissues. A. LASNITZKI. *Z. Krebsforschung* **22**, 536-9(1925).—Glycolysis of tumor tissue contg. bacteria and of normal tissue was detd. by Warburg's manometric method, which was carried out under anaerobic conditions. In this method the CO_2 was measured which was released when lactic acid, formed through glycolysis, acted upon the NaHCO_3 of the Ringer soln. The amt. of glycolysis by normal tissue is about half as great as that by tumor tissue.

F. B. SEIBERT

Utilization of glucosone by the diabetic organism. S. J. THANNHAUSER AND M. JENKE. *Arch. exptl. Path. Pharmacol.* **110**, 300 16(1926).—In almost all of the cases of diabetes which received glucosone the urine became both sugar-free and acetone-free.

G. H. S.

Experimental pathological changes in the ultramicroscopic picture of blood coagulation. MAKOTO WATANABE. *Arch. exptl. Path. Pharmacol.* **110**, 335-41(1926).—Ultra-microscopic observation of fibrin formation in plasma obtained by centrifuging fresh rabbit blood showed that during As poisoning as in complete deprivation of water the deviations from the normal form of blood coagulation were as had been previously noted by Masuda in rabbits with an infectious enteritis.

G. H. S.

Parathyreoprival tetany and guanidine intoxication. PAUL NOETHER. *Arch. exptl. Path. Pharmacol.* **111**, 38-41(1926).—In parathyreoprival tetany of cats the amt. of

detectable guanidine present is but very slightly increased over the normal content. This would indicate that parathyreoprival tetany is not a guanidine intoxication.

G. H. S.

H—PHARMACOLOGY

ALFRED N. RICHARDS

The effect of pituitrin on blood and on lymph and urine production. E. C. BAYLEY, J. C. DAVIS, W. WHITMAN AND F. H. SCOTT. *Proc. Soc. Exptl. Biol. Med.* 22, 312-4 (1925).—Twenty dogs were given injections of 2-3 cc. of obstetrical pituitrin (Park Davis Co.); 16 of these showed no change in the concn. of hemoglobin in the blood. 1 showed a decrease; and 3 showed a considerable increase in concn. Pituitrin caused a marked slowing of the flow of lymph from the thoracic duct and a temporary decrease in the excretion of urine; this was followed by diuresis when the blood pressure increased. Pituitrin decreases the permeability of capillary cells. C. V. B.

Action of sugars on gastric secretion investigated by means of Pavlov's small stomach. A. CIMINATA. *Arch. farm. sper.* 39, 49-83 (1925).—Subcutaneous injection of sucrose had no effect on gastric secretion, which differs in this respect from other secretions which are increased or diminished according to the amt. of sugar injected.

A. W. DOX

The action of calcium and potassium ions upon the cardiac fibers of the vagus in the frog. J. TEN CATE. *Pavlov's Jubilee Vol.* 1925, 55-9; *Physiol. Abstracts* 10, 152. After perfusion of the frog heart with 3.28% glucose soln. free from K and Ca, stimulation of the vagus nerve ceases to cause arrest of the heart. C. believes this effect to be due to depletion of the heart of its K and Ca, and not to a change in the $(K + Na)/Ca$ ratio. This latter is regarded as important only in detg. the activity of the cardiac muscle itself, but without influence on the vagus. H. G.

The influence of calcium on the power of the heart. M. J. E. M. STREYNS. *Onderzoek. Physiol. Lab. Utrecht* 5, 189-211 (1925); *Physiol. Abstracts* 10, 154.—Ca enables the heart to exert power proportional to its dosage in the perfusing fluid. At the same time the capability of the heart to stretch decreases as the Ca dose increases. This decrease is one of the factors which enables the heart to exert power. To measure power accurately, the perfusing fluid must have its K replaced by Ra emanation, because K, besides its effect on automatism, has a tonolytic and in big doses a negative inotropic action which is not possessed by emanation. In the series Be, Mg, Ca, Sr, Ba, the only metal which can replace Ca to any extent is Sr. H. G.

Calcium and myogenic heart properties. A. v. D. WILLIGEN. *Onderzoek. Physiol. Lab. Utrecht* 5, 170-88 (1925); *Physiol. Abstracts* 10, 154.—Ca exerts hardly any influence on the automatism of the frog's heart; it has no effect on the cond. and irritability, but decreasing the Ca in the perfusing fluid causes a great diminution in the height on contraction on elec. stimulation of the heart-point. Removal also causes disappearance of tonus, both "plastic" and elastic. H. G.

The influence of potassium on the intestinal movements. E. H. JANNINK. *Onderzoek. Physiol. Lab. Utrecht* 5, 13-27 (1925); *Physiol. Abstracts* 10, 160. An app. is described for obtaining continuous perfusion of the intestine and removing all substances made by the tissues. The small intestine carries out in perfusion expts. automatic movements dependent on temp., O₂, balancing of Ringer and Tyrode soln., the presence of choline and of a radioactive ion. Complete removal of K by prolonged perfusion with K-free Ringer causes stoppage of contractions. Removal of choline does likewise. If U is added to the perfusion fluid it is only absorbed into the cells in the presence of fluorescein, which apparently acts as a sensitizer. The first effect of the uranyl ion is to antagonize the K automaticity; increasing the dosage causes automatic movements based on U. Choline is necessary probably because it sensitizes the intestine to the action of K. H. G.

The influence of insulin on metabolic processes. A. KROGH AND P. BRANDT-REHBERG. *Pavlov's Jubilee Vol.* 1925, 91-103; *Physiol. Abstracts* 10, 171.—Expts. are described on the gaseous metabolism and blood sugar of urethanized and curarized rabbits after a dose of insulin. In animals under urethan or curare, the blood sugar can be brought down below the convulsive level without convulsions. The total metabolism remains on the whole unaffected by insulin, at least in doses which are not excessive. The respiratory quotient rises shortly after injection of insulin, and reaches a max. in 1 to 3 hrs. It never rises above unity, and only rarely reaches 0.95. The mechanism of the rise is discussed, and reasons are given for the conclusion that it is mainly due to an increased combustion of carbohydrate. Insulin is considered as part of the mechanism

for regulating the distribution of the metabolism between the different oxidizable substances available. Many original protocols are given. H. G.

The intervention of excitoperistaltic substances in the action of opium alkaloids on the intestine. J. LA BARRE. *Arch. intern. pharmacodynamie* 29, 179-303(1924); *Physiol. Abstracts* 10, 186.—An extensive study of the action of the various alkaloids, singly and in combination, with doses varying in size. The results depend to a certain extent on the choline content of the intestine. No abs. correlation between chem. constitution and action of the substances could be established. The opium preps. best calcd. to set the intestine at rest would appear to be "opon" (a mixt. of hydrochloride of the various alkaloids *without* morphine) and Straub's narcophine. H. G.

The point of action of certain drugs acting in the periphery. III. The action of pilocarpine upon the smooth muscle of the blood vessels. E. E. NELSON AND G. F. KEIPER, JR. *Arch. intern. pharmacodynamie* 29, 11-7(1924); *Physiol. Abstracts* 10, 187.—On intravascular administration of pilocarpine, clear effects on the blood vessels were observed. Dilatation, apparently by an action on the arterioles, occurred in the hind-limb vessels of the frog and also in the cat. Large doses of the alkaloid cause contraction of vascular smooth muscle. The generalization that "pilocarpine stimulates smooth muscle" is unjustifiable. H. G.

Effects of iodine on blood pressure. D. BOUDREAU. *J. méd. Bordeaux* 7, 279-80 (1925); *Physiol. Abstracts* 10, 188.—The effects of I on the blood, heart, muscle and vascular walls may either reduce blood pressure when high or raise it when low. H. G.

Emanation as a potassium substitute. H. ZWAARDEMAKER. *Pavlov's Jubilee Vol* 1925, 61-8; *Physiol. Abstracts* 10, 190.—K ions may be replaced by other sources of microradioactivity. The most suitable source of radioactivity is Rn in doses from $1/300$ to several microcurie per l. Rn can replace K only temporarily. After a certain time the effects of the absence of the chem. properties of K assert themselves, and these cannot be supplied by Rn. Rn becomes very readily adherent to cellular surfaces and can be removed by washing only with difficulty. The action of Rn is augmented by the presence of Ca ions. In order to maintain a regular rhythm of the heart the ratio of the concn. of ions should be K/Ca, Pb/Ca, U/Ca, Th/Ca = const.; but for Rn the concn. should be $Rn \times Ca = \text{const.} = 2 \times 4.10^{-10}$ (Rn in curie, Ca in mol.). The minimal concn. for Rn is $1/300$ microcurie and for Ca about 0.5×10^{-4} mol. H. G.

The effect of choline on the intestine of the rabbit. K. J. KRIEGER AND G. NOAH. *Z. ges. expil. Med.* 43, 661(1924); *Physiol. Abstracts* 10, 222.—The oscillations and the peristalsis of the small intestine increase. H. G.

Antagonistic action of insulin and pituitary extracts. G. JOACHIMOGLU AND A. MERZ. *Deut. med. Wochschr.* 50, 1787(1924); *Physiol. Abstracts* 10, 228.—Different exts. of the pituitary body vary in the power of inhibiting the action of insulin on the blood sugar content and on the uterus of the guinea pig. Insulin antagonizes the action of pituitary ext. on the guinea-pig uterus if the 2 gland exts. are mixed together before addn. H. G.

Diabetes treated by insulin. CARLES AND CLARAC. *J. méd. Bordeaux* 102, 384 (1925); *Physiol. Abstracts* 10, 229.—A contrast of 2 examples of marked glucosuria differently affected by insulin. In one, with little or no wasting, but considerable trophic disturbance and high sugar loss, a rapid improvement was effected. In the other, presenting a much wasted condition and similar degree of glucosuria, scarcely a check was put to the downward course of the illness. H. G.

The relation between hypoglycemia and convulsions after insulin. F. LAQUEUR, A. GREVENSTUK AND S. F. DE JONGH. *Deut. med. Wochschr.* 51, 178(1925); *Physiol. Abstracts* 10, 228.—From a series of 3000 expts. on the standardizaion of insulin by injection into rabbits the authors conclude that a low blood sugar content in itself is not necessarily the causative agent in the production of convulsions, but that the low blood sugar gives rise to substances which excite these. Insulin, therefore, should not be standardized by its power of producing convulsions, but by its effect upon the blood sugar. H. G.

Influence of colloids on the action of drugs. W. STORM VAN LEEUWEN, A. V. SZENT-GYÖRGYI AND L. JENDRASSIK. *Arch. neerland. physiol.* 9, 442 8(1924). **Biological significance of some lipoids.** A. V. SZENT-GYÖRGYI. *Ibid* 448-9. **Pharmacological action of decomposition products of cephalin.** L. JENDRASSIK. *Ibid* 449-53; *Physiol. Abstracts* 10, 243-4.—Cephalin injected intravenously produces a fall of blood pressure; it also improves the action of the hypodynamic heart. Lecithin has no effect on blood pressure; it reinforces the hemolytic action of silicic acid and cobra venom; it forms a combination with peptone; and it is pptd. at pH 5.5. The reinforcement of

the action of pilocarpine, atropine, etc., upon the isolated cat's small intestine by a previous dose of rabbit serum has been traced to the activity of the lipoids, etc., of the serum. Cephalin enhances the action of pilocarpine and atropine, lecithin that of histamine, and antagonizes the action of cephalin. The action appears to be due to some unidentified decompn. product of cephalin. Among other substances examd., soap have the same property; Na oleate possesses it to a very marked degree. The same or a similar decompn. product also enhances the anesthetic action of novocaine on motor and sensory nerves, in the frog and mammals, resp. Rabbit serum forms a combination with pilocarpine or atropine; peptone and the general anesthetics prevent this; it is probable that the combination is an adsorption compd. Cf. *C. A.* 15, 1945; 17, 437.

H. G.

Choline and the gastrointestinal system. R. MAGNUS. *Münch. med. Wochschr.* 72, 249(1925); *Physiol. Abstracts* 10, 246.—Choline is the physiol. stimulant for Auerbach's plexus; atropine paralyzes it. This explains the conflicting reports on the action of atropine on the intestinal movements; when there is little choline atropine stimulates the plexus. Choline produces only normal movements, not spasms. It is effectual in exptl. paralysis of the bowel in animals (peritonitic, CHCl_3 anesthesia) in doses of 10 mg. per kg.; 35 mg. of choline-HCl is fatal if injected rapidly.

H. G.

The action of potassium ions on the blood sugar picture. F. KYLIN AND A. ENGI. *Klin. Wochschr.* 4, 653(1925).—KCl, injected intravenously, lowers the blood sugar.

MILTON HANKE.

Antagonistic action of insulin and atropine on the vagus nerve in blood pressure experiments. ERNST FREY. *Klin. Wochschr.* 4, 501-2(1925).—Stimulation of the vagus nerve leading to an isolated frog heart leads to a reduction in the pulse rate. Insulin does not stimulate the vagus because it produces, if anything, an accelerated pulse rate. Atropine is without effect in the latter case. Atropine reduces the pulse rate of a rabbit heart because of its action on the vagus. Insulin counteracts the action of atropine; the pulse rate increases and becomes normal. Insulin displaces atropine from the nerve fiber.

MILTON HANKE.

The action of ephylline diuresis on normal and disturbed water balance. W. KEMP MANN AND H. MENSCHEL. *Klin. Wochschr.* 4, 308-10(1925).—Ephylline is a diuretic. Ingested KOAc or KCl and injected CaCl_2 are not diuretic in the concns. employed in the expts. Normal persons that have been treated for 8 days with K or Ca salts are in a state of disturbed water balance. Treatment with ephyllin now leads to a profound diuresis associated with a loss in body weight, concn. of the blood and a subsequent water retention. The loss in H_2O via the lungs and skin is, not infrequently, also greatly increased.

MILTON HANKE.

The supposed erythrocyte-generating action of germanium dioxide. WERNER KEIL. *Klin. Wochschr.* 5, 62-3(1926).—Injection of K_2GeO_3 into rabbits (10 mg GeO_2 per kg. body wt. on alternate days) has no effect upon the erythrocyte count nor upon the hemoglobin.

MILTON HANKE.

The detoxicating effect of glucose in guanidine poisoning. JOSEF BAKUCZ. *Klin. Wochschr.* 5, 70-1(1925).—Guanidine poisoning, in animals, is associated with hypoglycemia. The fall in blood sugar begins with tetany and parallels the severity of the symptoms. Administration of glucose, intravenous or peroral, has no effect upon the tetany; glucose does not function as a detoxicator in this case.

MILTON HANKE.

Increased resorption due to the action of insulin. OSKAR KOREF AND HANS MAUTNER. *Klin. Wochschr.* 5, 191(1926).—Curare is not poisonous, when ingested, because it is not absorbed from the intestinal tract. Insulin poisoning is associated with an increased absorption rate if, indeed, not with qual. changes in absorability because, in insulin-treated animals, curare is absorbed from the intestinal tract and leads to death with typical symptoms. The toxicity of curare, given perorally, is directly proportional to the intensity of the insulin poisoning as measured by the degree of hypoglycemia. Other expts. indicate that milk and an 8% soln. of MgSO_4 are absorbed from the intestinal lumen under the action of insulin.

MILTON HANKE.

Chemotherapeutic studies with gold. ADOLF FELDT. *Klin. Wochschr.* 5, 299-301(1926).—Inorg. gold salts are bactericidal, but poisonous. The therapeutic index is about 1:1, i. e., the dose required to kill the host is about equal to that required to destroy the invader. Org. gold compds. have the general formula R-S-Au. It has been possible to prep. org. gold compds. with a therapeutic index of 1:10 (staphylococci and *Spirochaeta febris recurrens*). Such compds. are harmless because only one tenth of a lethal dose, for the host, will destroy the invader. The expts., so far, have been limited to animals. The possibility of using gold salts in the treatment of tuberculosis is mentioned. Hg is, on the whole, a poor element for chemotherapy because bactericidal

action and toxicity, to the host, are parallel functions in the majority of compds.; in short, the therapeutic index of most Hg compds. is 1:1. MILTON HANKE

Disappearance from the blood plasma of intravenously injected dyes. ANNELEISE WITTGENSTEIN AND H. A. KREBS. *Klin. Wochschr.* 5, 320(1926).—Basic dyes, such as fuchsin, safranin, brilliant cresol blue, methylene green, neutral red and methylene blue, disappear from the circulation to the extent of 99% in 1 min. The remaining 1% disappears within 1 to 2 hrs. Acid dyes such as uranine, patent blue V, echtgelb, orange G, eriocyanin, chrysolin, acid fuchsin, light green SF, Congo red, trypan blue and water blue disappear from the circulation to the extent of 20-90% in 1 min. The remaining dye can be demonstrated for 5 hrs (uranine) to 2 months (water blue). The disappearance of the acid dyes is a function of their degree of dispersion. The colloidal dyes (trypan blue, water blue VI B and Congo red) disappear more slowly than the crystalloidal dyes. The degree of dispersion is not the only factor. Congo red and water blue are equally dispersed; but Congo red circulates for 3 days and water blue for 2 months. Those triphenylmethane dyes that circulate as colorless carbinols (acid fuchsin, light green and water blue) leave the circulation more slowly than other dyes of equal dispersion. Basic dyes are far more toxic than acid dyes. The conditions in the body are such that basic dyes are readily adsorbed by the cellular colloids. Acid dyes are poorly adsorbed. This explains the greater toxicity and speed of migration of the basic dyes. MILTON HANKE

Action of pyridone on the musculature of the intestine. H. JANUSCHKE AND F. LASCH. *Klin. Wochschr.* 5, 321(1926).—Pyridone, in a concn. of 1:10,000, relaxes the tonus of the isolated guinea-pig intestine. It promptly removes the spasm produced by BaCl₂ or pilocarpine. Pyridone is also spasmolytic in the intact animal. MILTON HANKE

Influence of calcium on elevated blood pressure. WILFRIED LOEWENSTEIN. *Klin. Wochschr.* 5, 354-7(1926).—CaCl₂ ingested does not change the normal blood pressure. Injection of 10 cc. of a 10% soln. gives rise to a hot feeling. The blood pressure is restless, rises above normal, subsides to normal then rises and subsides again; but comes to rest within an hr. Entirely similar results are obtained with equiv. amts. of NaCl, NaI and SrBr₂ and with a 50% soln. of glucose, so this seems to be a hypertonicity effect rather than something specific. The results obtained with high blood pressure cases are quite different. The salts of univalent metals reduce the blood pressure slightly; but the effect lasts for scarcely 1 hr. The bivalent metals are far more effective. In the case of Ca and Sr salts the blood pressure may be reduced for 24 hrs. Re-injection at this time again lowers the blood pressure. The effectiveness of the bivalent metals is directly proportional to their atomic numbers. MILTON HANKE

Lysocithin as a poison. S. BELFANTI. *Rend. d. adunanze dell'accad. med. fis. fiorentina; Sperimentale* 79, 932-6(1925).—Not only cobra venom but also that of *Crotalus terrificus* and *Lachesis Newedii*, and even the poison of the bee are sufficient to convert the lecithin of egg-yolk into lysocithin (I), the action consisting in removal of the oleyl radical. Lipoidal exts. of the pancreas and salivary glands of cattle and horses contain a similar, preformed, highly hemolytic lysocithin ("substance Y"). The toxicity of I for animals is discussed, and expts. are referred to tending to show that poisoning by venom is due to its action in converting lecithin of the poisoned organism into I. The close analogy of hemorrhagic septicemia and anthrax is emphasized. Wasp poison differs from those of the hornet and bee in that it bleaches egg-yolk and coagulates the lecithin, apparently degrading it beyond I and producing only a weak hemolysis whose power is lost within 48 hours. From this was isolated an insol. crystalline fatty acid contg. H₃PO₄. The residue, extd. with Et₂O, again becomes strongly hemolytic. M. HEDELBERGER

Hemorrhagic action of lysocithin. G. GUERRINI. *Rend. d. adunanze dell'accad. med. fis. fiorentina; Sperimentale* 79, 936-7(1925).—Lysocithin prepd. with the aid of venom from *Crotalus terrificus*, or *Apis mellifica* poison, causes capillary hemorrhages when instilled into the conjunctival sac of dogs and rabbits, also in the kidney when injected into the renal artery, thus acting as a true capillary poison and supporting the conclusions of Belfanti (see preceding abstract). M. HEDELBERGER

Aloes socotrina. H. S. STIMPSON. *J. Am. Inst. Homeopathy* 19, 101-4(1926).—Tincture of aloes was administered to rabbits by mouth, intravenously, subcutaneously and intraperitoneally. The respiration was slowed, the blood pressure lowered and the heart rate increased. Large doses produced speedy death. Smaller doses produced purgation, with frequent watery stools and passive congestion of the rectal mucosa. The rate of the isolated heart was decreased. The isolated contracting uterus ceased to contract. The isolated large intestine showed an increase in tonus, a number of

contractions and a decrease in their size. Isolated segments of small intestine from the region of the pylorus showed an increase in tonus and size of the contractions but a decrease in the rate of contraction. The remainder of the small intestine was characterized by a decreased tonus and an increase in the size of the contractions. J. S. H.

Comparative studies of the action and the mode of action of calcium and digitalis. ERNST BILLIGHEIMER. *Z. klin. Med.* 100, 411-57(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 310(1925).—Atropine tachycardia is not perceptibly influenced by Ca. In adrenaline tachycardia a slowing of the pulse of up to 50% is caused, after the drop in blood pressure has taken place. The excessively slowed vagus pulse (*i. e.*, after digitalis) is not influenced by Ca. Conclusion: Ca attacks the vagus endings. In the human being Ca and digitalis have the same site of attack and the same effect. There is a mutual enhancement of the effect on the heart. The Ca level of the blood is affected by digitalis. On the other hand cases with a high blood Ca (encephalitis) have a much higher tolerance to digitalis than those with a low Ca (tetany). The vasoconstrictor effect of Ca is much lower than that of adrenaline and rarely if ever reduces blood pressure. The vagus stimulation is followed by a greater responsiveness of the sympathetic. Therapeutically Ca is indicated in all cases of tachycardia of not purely central nervous origin and in absence of a too gross injury to the vagus. The best results were obtained in myocarditis. Cases with a negative Ca test (no slowing of the pulse after injection) do not respond to digitalis. If the Ca test becomes positive after a few days' digitalis treatment then this treatment may still be successful. For the numerous details see the original. MARY JACOBSEN

The immunity to plant poisons as studied on pyroline. SEBASTIANO ZISA. *Arch. di patol. e clin. med.* 3, 290-304(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 311-5(1925).—Prolonged administration of small doses of pyroline (acetylphenylhydrazine) immunizes dogs and rabbits against its destructive action on blood cells *in vivo* and *in vitro*. The immunity is cellular, histogenetic, not humoral of the antibody type, since the serum of immunized animals has not only no protective but even an aggravating effect in pyroline poisoning. MARY JACOBSEN

Pharmacological studies of the uterus by the "abdominal window" method. F. LUDWIG AND E. LENZ. *Z. Geburtshilfe Gynakol.* 87, 115-28(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 459(1925).—The method is described in a previous paper. The pendulum movement of the uterus cannot be sepd. from the peristaltic movement, as it can in the intestine. Certain contractions are characteristic for certain agents. Adrenaline checks immediately all the motions of the rabbit uterus. The initial intense anemia is later followed by hyperemia. The peristalsis of the gravid rabbit uterus is considerably increased and accompanied by moderate anemia. The main effect of pituitrin on the pregnant and non-pregnant rabbit and cat uterus is tetany with 3 different stages. Placental ext. increases the peristalsis and the blood supply considerably. The very persistent effect of secacarin is characterized by a max. contraction which is replaced successively by a stationary tonic ring contraction, annular peristalsis and finally normal peristalsis with increased tonus. Gynergen has the same effect. Uteramin creates a permanent tonic contraction which gradually gives way to an increased peristalsis of the normal type with higher tonus and free from the constriction rings characteristic for secacarin and gynergen. Atropine causes a prolonged complete relaxation of the non-pregnant uterus of the rabbit. MARY JACOBSEN

The effect of insulin given by mouth. CASIMIR FUNK AND SOPHIE KMLODZIEJSKA. *Medycyna doswiadczalna* 2, 367-8(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 58(1925).—The effect of an alc. soln. introduced by the stomach tube (Winter) is unreliable and without practical value. Stomachal introduction of an aq. soln. causes an increase of blood sugar, apparently owing to absorption of antagonistic substances, which are contained even in the purest preps. MARY JACOBSEN

The pharmacodynamics of atropine and adrenaline. L. F. BACKMANN AND HARALD LUNDBERG. *Uppsala läkareförenings förhandl.* 30, 1-115(1924); *Ber. ges. Physiol. exptl. Pharmakol.* 30, 646-8(1925).—A detailed review. MARY JACOBSEN

Twelve cases of carbon tetrachloride poisoning. M. STRAUB. *Geneeskundige Tijdschr. Nederland. Indie* 65, 624-45(1925).—The poisoning was characterized by kidney and liver lesions. Two cases were fatal. The probable mechanism of the poisoning is discussed. Alc. abuse seems to increase the susceptibility. M. J.

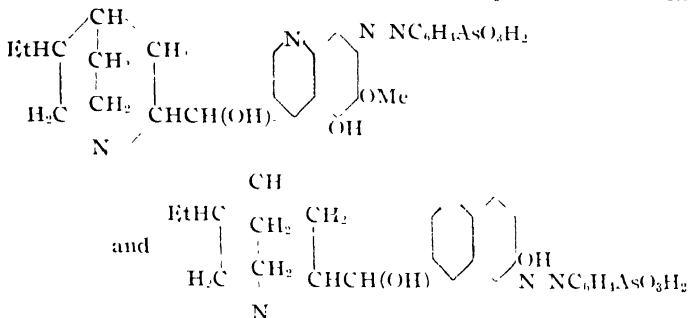

Carbon tetrachloride as a hookworm remedy. W. KOUWENAAR. *Geneeskundige Tijdschr. Nederland. Indie* 65, 646-57(1925).—Even pure CCl₄ causes poisoning, in some cases death. Liver diseases and alcoholism are predisposing factors. M. J.

The action of ultra-violet rays on rachitic manifestations. U. FERLI. *Pediatrics (Riv.)* 33, 1197-212(1925).—From 14 to 15 irradiations of 5-15 min. every second day

may result in complete recovery, if aided by general hygienic measures. The irradiations can be discontinued before the disappearance of the lesions on the radiogram. In nurslings the radiogram does not always permit estimation of the extent of the rachitic process, as a considerable retardation of ossification is often disguised by seemingly insignificant lesions.

MARY JACOBSEN

The action of quinine and quinine derivatives on nagana trypanosomes. A. GIEMSA. *Arch. Schiffs-Tropen Hyg.* **29**, 479-85 (1925).—Discussion and report of the *p*-arsonophenylhydrocupreines that have been suggested as possible anti malaria prepus.:

FRANCES KRASNOW

Intra-arterial anesthesia in dogs. J. P. ARLAND. *Indian J. Med. Research* **13**, 263-4 (1925).—No motor paralysis is obtained, the anesthesia probably being due to paralysis of nerve endings. Dogs take cocaine very well.

F. K.

Effects of quinine on the sugar of the blood. T. A. HUGHES. *Indian J. Med. Research* **13**, 321-36 (1926).—"The effect of insulin on the hyperglucemia produced in rabbits by large doses of quinine is similar to its effect on adrenaline hyperglucemia. Irgotoxin and, in a smaller degree, pituitrin inhibit the glycogenolytic effect of quinine. Quinine, in antimalaria doses, usually causes a lowering of the blood sugar in man. This effect is antagonized by pituitrin. The fall in blood sugar produced by quinine in man may in certain cases give rise to mild symptoms of hypoglycemia. These symptoms can be prevented by the ingestion of carbohydrates or carbohydrate-rich meal $\frac{1}{2}$ to 1 hr. after the drug is taken."

FRANCES KRASNOW

Certain observations on the mechanism of quinine hemoglobinuria in man. I. U. N. BRAHMACHARI AND P. B. SEN. *Indian J. Med. Research* **13**, 337-41 (1925).—"In individuals susceptible to quinine hemoglobinuria, quinine probably remains adsorbed with an unknown substance in the liver for prolonged periods giving rise to a concn. of the drug, at which quinine hemolyzes red corpuscles in the test tube." "Whether hemolysis will take place in the liver will depend upon (1) the concn. of the quinine in the liver and (2) the period during which such a concn. is maintained." No hemolysis was discovered in the peripheral blood during the active stages of quinine hemoglobinuria.

FRANCES KRASNOW

Studies in malaria, with special reference to treatment. I. **Introduction and routine methods.** J. A. SINTON. *Indian J. Med. Research* **13**, 565-78 (1926). II. **The effect of treatment on the prevention of relapse in infections with *Plasmodium falciparum*.** *Ibid* 579-601.—Conclusions are based on 800 cases of malignant tertian malaria, observed under carefully controlled conditions. If this infection is treated for one week with 30 grains of quinine daily, combined with the alkaline treatment, 80% of the cases may be cured. Thirty grains of quinine daily for one week, cinchona febrifuge or cinchona febrifuge and alkali will cure about 50% of malignant tertian infections. Patients infected with *P. falciparum* lend themselves to treatment more readily than those infected with *P. vivax*. III. **The value of "provocative methods" in the diagnosis of uncured malaria infections.** J. A. SINTON, B. RIVAS, J. D. BAILY AND DIVAN CHAND. *Ibid* 603-16.—Little or no advantage was gained in the diagnosis of uncured malarial infections by the use of injections of adrenaline or strychnine.

F. K.

Certain observations on the mechanism of quinine hemoglobinuria in man. II. U. N. BRAHMACHARI. *Indian J. Med. Research* **13**, 695-6 (1926).—A patient giving a history of malarial attacks was now suffering from kala-azar. It was the first appearance of hemoglobinuria. The hemolysis was going on in the liver just as in cases of quinine hemoglobinuria.

FRANCES KRASNOW

Protein therapy and phlorhizin glucosuria. A. FISCHER AND H. WEISS. *Biochem.*

Z. 159, 141-5(1925).—A casein soln. was injected into dogs made diabetic with phlorhizin. The D/N ratio dropped slightly in nearly all and markedly in a few cases. The same was true when serum was used in place of the casein. Therefore, protein seems to aid the metabolism of carbohydrates in phlorhizin diabetics. W. D. L.

The effect of narcophine upon the digestion of meat in dogs. E. ZUNZ. *Arch. intern. pharmacodynamie* 30, 1-63(1925).—Upon subcutaneous injection of 4-16 mg. of narcophine (a double meconic acid salt of morphine and narcotine) the following effects were observed: The meat remained a longer period of time in the stomach and was attacked more slowly by the digestive juices than normally; the acid albumin content of the various parts of the digestive tract is increased; the stomach contained less of proteoses and more of peptones and of abiuret substances, while the intestine contained more proteoses and less of peptones and of abiuret substances than normal; an increase of NH_3 - and $\text{NH}_4\text{-N}$ was frequently observed in the stomach contents. These effects were roughly proportional to the amt. of narcophine given. W. A. PERLZWEIG

The action of eserine and atropine on the isolated intestine of the rabbit. A. D'HAENENS. *Arch. intern. pharmacodynamie* 30, 77-111(1925).—The isolated rabbit intestine reacts *in vitro* to eserine in the same way as it does to pilocarpine. But atropine, which almost always abolishes the effects of pilocarpine, accentuates the action of eserine. W. A. PERLZWEIG

Plain-muscle stimulants in body fluids. S. DEBOER, N. B. DREYER AND A. J. CLARK. *Arch. intern. pharmacodynamie* 30, 141-7(1925).—"Vasoconstrictor and oxytocic substances appear slowly in fluid which has been introduced into the peritoneal cavity. Such peritoneal fluid has about $1/4$ the oxytocic action, but has only about $1/20$ the vasoconstrictor action of serum. Cerebrospinal fluid of the dog usually has feeble vasoconstrictor and oxytocic actions. When pituitary ext. is injected intravenously, it disappears from the blood stream in about 30 min., but no evidence has been obtained that the oxytocic or melanophore dilator principles pass into the peritoneal cavity. In 2 expts. the injection of pituitary ext. caused the appearance of excess of oxytocic substances in the cerebrospinal fluid. The majority of such expts. gave negative results." W. A. PERLZWEIG

The toxicity of serum treated with agar-agar. A. LUMIÈRE AND H. COUTURIER. *Arch. intern. pharmacodynamie* 30, 151-3(1925).—Polemic with Bordet on the interpretation of anaphylactic phenomena induced by the injection into animals of homologous serum treated with agar-agar. W. A. PERLZWEIG

The influence of injection of bases and acids on body reaction. A. LUMIÈRE AND M. SORS. *Arch. intern. pharmacodynamie* 30, 157-69(1925).—"The injection of relatively large doses of alkali (NaOH or Na_2CO_3) into the veins or directly into the heart of guinea pigs, when not fatal, brought the reaction of the blood to p_{H} 9.6, the reaction falling to normal (p_{H} 7.3-7.4) within several hours. Intravenous injections of HCl solns. brought the p_{H} of the blood to 5.6; it rose to normal within a few hours. The same amt. of HCl injected into the left heart was fatal, while it was innocuous when injected into the right heart. Repeated injections of acid or base did not produce any permanent effect upon the reaction of the blood. The addition of acid and base to blood *in vitro* in relatively the same proportions as were used in the above expts. *in vivo* changed the reaction of the blood to p_{H} 6 and 8, resp. W. A. PERLZWEIG

Chloroform and ether. Amounts necessary at different stages of anesthesia. L. DECKERS. *Arch. intern. pharmacodynamie* 30, 229-49(1925).—The results of expts. are given which appear to modify some of the established (European) standards of dosage for general anesthesia. W. A. PERLZWEIG

The influence of chloroform combined with hypnotics upon general excitability in frogs. G. SORBI. *Arch. intern. pharmacodynamie* 30, 251-3(1925).—Iodoform possesses a clearly defined depressing action on reflex excitability. Hypnotic drugs combined with CHI_3 cause an increase in the general excitability in frogs. W. A. P.

Experimental lead poisoning. G. PENNETTI. *Arch. intern. pharmacodynamie* 30, 255-74(1925).—Chiefly an histologic study with small animals. W. A. P.

Poisons of the local or metasympathetic nervous system of the intestine. F. WARMOES. *Arch. intern. pharmacodynamie* 30, 171-227(1925).—The inhibitory action of adrenaline upon the intestine is abolished by atropine or strychnine applied previously or subsequently. But adrenaline always retains its influence upon the tonus, causing the max. of intestinal relaxation after any contraction induced by any of the nerve poisons. Further results of a great variety of combinations of the following drugs applied one after another to the same segment of intestine in an oxygenated bath of Ringer soln. are given: adrenaline, atropine, strychnine, nicotine, cocaine, pilocarpine, eserine, digitalis, quinine, pituitrin, ergotamine. W. A. PERLZWEIG

The localization of arsenic after intravenous injection. A. D' HAENENS. *Arch. intern. pharmacodynamie* 30, 291-309(1925).—The distribution of As in the various organs and body fluids of rabbits after injection of neoarsphenamine, cacodylates and of Fowler's soln. are presented in numerous tables. The spleen, heart, lungs and intestine showed a surprising selective affinity for As and much less in the case of the liver. When administered in the inorg. form As was found to remain in the blood stream about 10 times as long as in the org. forms. W. A. PERLZWEIG

A pharmacodynamic and toxicologic study of somnifene. T. A. REDONNET. *Arch. intern. pharmacodynamie* 30, 321-51(1925).—Somnifene is a 25% aq. soln. of equal parts of diethylbarbituric acid (barbital) and of diethylamine diallylbarbiturate. R. finds it to be greatly superior to other barbituric acid derivs. as a hypnotic for clinical purposes. W. A. PERLZWEIG

Physiology of abnormally induced hypothermia. C. AMSLER. *Arch. expl. Path. Pharm.* 107, 260-70(1925).—Doses of picrotoxin or of Na sautoin which of themselves induce no manifestations in rabbits render the pain centers more sensitive. G. H. S.

Effect of temperature on the occurrence of convulsions in strychnine intoxication. B. H. SCHLOMOVITZ AND S. A. MACHLIS. *Arch. expl. Path. Pharm.* 111, 1-31(1926).—Analysis of the relation of the temp. to the time of onset of strychnine twitches in frogs shows, when subjected to mathematical treatment, a formula corresponding to van't Hoff's law. In the effects which variations in body temp. have on the onset of the strychnine convulsions the heart beat plays only a subsidiary role. G. H. S.

Effect of strophanthin on the absolute power of the frog heart. E. GRIGER AND L. OROSZ. *Arch. expl. Path. Pharm.* 111, 32-7(1926).—Digitalis substances do not increase the abs. power. Under certain circumstances of weakened heart action they tend to restore the power, but, in contrast to caffeine, the activity of the heart is never carried beyond its av. normal initial value. G. H. S.

Transfer of chemical substances from the blood vessels to the tissues. CHUYUNG PAK. *Arch. expl. Path. Pharm.* 111, 42-59(1926).—By employing the method of perfusion with isolated organs it is shown that alkaloids penetrate the vessel wall about as readily as do NH_4Cl , urea, glucose and dihydroxyphenylalanine. Although with many alkaloids the deposition in the muscle tissue of cold-blooded animals is very marked, even after a very protracted period of perfusion the transfer of these alkaloids to the tissues is not arrested. Strophanthin and verodigen also pass readily through the vessel wall, although they are not stored in the tissues. Adrenaline passed through the muscle tissue of both cold- and warm-blooded animals is not destroyed in the tissue, but in the liver of the warm-blooded animal the destructive capacity is so highly developed that even with a very long period of perfusion the transfer to the cells does not stop. G. H. S.

Pharmacological properties of pure apocodeine. OTTO KRAVER. *Arch. expl. Path. Pharm.* 111, 60-7(1926).—Apparently the expts. hitherto performed with apocodeine have been made with impure prepns. Cryst. apocodeine is some 5 times as active as the amorphous com. Apocodeine. On the other hand there is no important qualitative difference between the action of the pure and the com. prepns. Pure apocodeine has a definite narcotizing effect on dogs and through a direct action stimulates the intestine to defecation. It paralyzes the sympathetic ganglia cells and has an emetic effect strikingly like that of apomorphine. G. H. S.

Pharmacology of tetrophan. ERICH HESSE. *Arch. expl. Path. Pharm.* 111, 68-80(1926).—Tetrophan tetany can be induced by suitable procedures either with or without a lactic acid accumulation in the muscle, the degree of tetany in both cases being the same. G. H. S.

Action of thiocyanate on muscle and the reciprocal strengthening of the action of contraction-producing agents. MASAYUKI OKAGAWA. *Arch. expl. Path. Pharm.* 111, 99-113(1926).—Subreactive concns. of NaSCN induce maximal contraction of the isolated frog muscle, if they are combined with subreactive concns. of HCl , NaOH and especially KCl . The capacity of NaSCN to cause muscle twitching is considerably increased by these substances. The effect of weak doses of acetylcholine or of caffeine on the muscle is considerably increased by the addn. of an inactive amt. of thiocyanate. The same effect takes place by the combination of NaI or dimethylguanidine with other substances. Subreactive concns. of NaSCN , NaI and dimethylguanidine chloride mutually strengthen each other as regards the production of muscle twitching, but do not cause contraction. In Ca -free Ringer soln. all of the contracting substances studied show an increased activity. Amts. of Na citrate which tend to induce activity give a stronger action with NaSCN , and this is rendered more intense by the lack of Ca . It

must be assumed that citrate manifests a complex type of action. Novocaine abolishes or prevents the fibrillar twitching due to NaSCN. The antagonistic action of novocaine for thiocyanide contraction is limited. Narcosis in muscle is removed by thiocyanide. G. H. S.

Convulsion-arresting action of *Adonis vernalis* and *digitalis*. M. MASSLOW. *Arch. expl. Path. Pharm.* 111, 114-25(1926).—Large doses of *Adonis vernalis* exert a quieting and paralyzing effect on the nervous system of rabbits and can protect the animals against experimentally induced convulsions. The point of attack is in the cerebrum (cocaine convulsions), in the medulla (camphor convulsions) and in part in the spinal cord (picrotoxin convulsions). It is entirely without action as regards the reflex sensory centers and the motor nerve endings of skeletal muscle. The ability of *digitalis* to abolish convulsions is less marked, although it may weaken them. With *digitalis* the medulla is the primary point of action, the cerebrum being less involved and the spinal cord and motor nerve endings unaffected. G. H. S.

Hydrogen sulfide intoxication by the external application of elementary sulfur in the form of salves. FELIX BASCH. *Arch. expl. Path. Pharm.* 111, 126-32(1926).—When salves which contain S are rubbed into the skin which has been previously damaged by either a pathol. process or by some mech. manipulation an absorption of S occurs (the intact skin absorbs but little) leading to a H₂S intoxication. Both the blood and the urine reveal the presence of H₂S and at certain periods it is eliminated by way of the respiratory tract. The pathol. findings are those of a chronic H₂S intoxication. G. H. S.

Mode of action of insulin. I. Insulin and the glucose distribution between fluid and non-fluid systems. H. HAUSLER AND O. LOEWI. *Arch. ges. Physiol.* (Pflüger's) 210, 238-79(1925).—Glucose added to a paste suspension of vessel tissue in NaCl soln. or in oxalate plasma or serum is not bound by the paste, but remains exclusively in the fluid system. In the presence of insulin, on the contrary, the glucose (about 6%) becomes united with the paste. No glucose combines with the red blood cells of the NaF bovine blood. In human NaF blood the added glucose becomes distributed, even in the absence of insulin, between the blood cells and the plasma; although the addn. of insulin increases the combination with the cells. In a glucose-free NaCl soln. human blood cells satd. with glucose give up less glucose when insulin is present than when it is absent. The extent of the effect of the insulin is in a definite manner dependent upon the glucose concn. of the system, the amt. of insulin, the quantity of red blood cells, and the character of the fluid system. As regards the last, the insulin effect is far weaker in NaCl soln. than in serum or plasma. In defibrinated bovine blood, under the influence of insulin there occurs, as in NaF blood, not only a binding of the added glucose to the blood cells, but also an abrupt disappearance from the blood. This disappearance is not the expression of a direct insulin action, but is purely a result of the fixation of glucose to the blood cells induced by insulin. This is rendered obvious by the fact that an abrupt disappearance of glucose occurs in a wholly similar manner in the absence of insulin, as when glucose combines with the red cells of human blood. It thus appears that before one can assume that insulin has a direct effect on carbohydrate metabolism, the induced, or augmented, combination of glucose with the cells or other structural elements by insulin must be considered as the primary cause of the change in carbohydrate metabolism. **II. Insulin and the phosphate and potassium content of the blood.** H. HAUSLER AND O. HEESCH. *Ibid* 545 9.—The diln. of the blood subsequent to bleeding is effected by a tissue fluid which is slightly poorer in inorg. phosphate and is much poorer in K than is the blood. At the height of the effect due to a subcutaneous injection of insulin the amt. of inorg. phosphate and of K in the blood is materially reduced. This loss is entirely independent of the blood diln., since it occurs when the latter is lacking. In *in vitro* tests insulin may cause a reduction in the glucose of the fluid system and an increase in that of the cells without modifying in any way the distribution of inorg. phosphate and of K. G. H. S.

Effect of adrenaline on the excretion of nitrogen, of creatinine, and of creatine. ALEXANDER PALLADIN AND WERA TICHWINSKAJA. *Arch. ges. Physiol.* (Pflüger's) 210, 436-41(1925).—If rabbits on a normal diet are given daily injections (1 per day) of adrenaline in gradually increasing amts. the excretion of total N and of creatinine are not modified. If, however, the rabbits are injected twice each day, and the amt. of adrenaline given is rapidly increased a markedly augmented excretion in total N and creatinine occurs, and creatine appears in the urine. G. H. S.

Comparison of the effects of *l*- and *d*-adrenaline under different conditions on the gas metabolism of normal and thyroidectomized mice. E. ABDERHALDEN AND ERNST GELLHORN. *Arch. ges. Physiol.* (Pflüger's) 210, 462-76(1925).—Injected subcutaneously

in warm-blooded animals *d*- and *l*-adrenaline lead to the same qual. changes in the gas metabolism. In low concns. the O use is increased; in high concns. it is diminished with a simultaneous fall in body temp. Quantitatively *d*- and *l*-adrenaline differ greatly since to attain a given effect it requires at least 10 times as much of the *d*- as of the *l*-adrenaline. Frequent injections of either *d*- or *l*-adrenaline lead to a tolerance for *l*-adrenaline, as is evidenced by the fact that the fatal dose for the normal mouse causes in the tolerant mouse the characteristic increase in metabolism usual for small amts. of adrenaline. Thyroidectomized mice show a considerably increased adrenaline resistance. Correspondingly, the O use even after the injection of 0.008–0.01 mg. of *l*-adrenaline per g. is increased, although in the normal animal under these conditions death occurs promptly with a marked fall in the O utilization and in body temp. The susceptibility of an animal to intoxication with adrenaline is considerably increased by fatigue. Even 0.004 mg. of *l*-adrenaline per g., or 5 to 10 times this amt. of *d*-adrenaline, will cause, with a simultaneous fatiguing, a complete exhaustion within a very short time (10 to 30 min.) followed usually by death. Normal control animals failed to show a comparable exhaustion even after 1½ to 2 hrs. In this behavior, thyroidectomized animals again showed an increased resistance. G. H. S.

Altering the glucose adsorption of human blood corpuscles by narcotics and lipoids. HANS HÄUSLER AND RAOUL MARGARIDO. *Arch. ges. Physiol.* (Pflüger's) **210**, 566–75 (1925).—Sodium oleate, thymol, camphor, isobutylurethan, Et₂O, and ethylurethan in low concns. inhibit, in higher concns. favor, glucose adsorption by human red blood cells. The same substances in the same concns. inhibit and favor the liberation of hemoglobin by the red cells caused by shaking. G. H. S.

Poisoning by sulfonal; localization of sulfonal and of hematoporphyrin. R. FADRE AND H. SIMONNET. *J. pharm. chim.* [8] **2**, 225–7 (1925).—A rabbit which was given a total of 12 g. sulfonal (*A*) with its food in 12 days was then killed, and the following amts. of *A* were found in the different organs: brain and marrow (wt. 11.5 g.) 0.057 g.; liver (48 g.) 0.043 g.; kidneys (15 g.) 0.028 g.; muscle (24 g.) 0.015 g.; blood (7.5 g.) 0.009 g.; spleen (0.8 g.) 0.007 g. The bile when examd. under ultra-violet rays having shown the fluorescence of hematoporphyrin (*B*), the distribution of *B* in the organs of another rabbit similarly treated was sought. *B* was found with certainty only in the bile, urine and in small quantity in the spleen. Seemingly, *B* formed in the course of poisoning by *A* is, in part, rapidly eliminated through the urine, and too small a quantity is left to be detected in the blood. S. WALDBOTT

MAIER, H. W.: **Kokainismus.** Geschichte, Pathologie, medizinische und behördliche Bekämpfung. Leipzig: Georg Thieme. 269 pp. Paper R. M. 15. Bound 17.50.

I—ZOOLOGY

R. A. GORTNER

Chemical study on pond-snails. NAOYE HASUI. *Okayama, Ig. Kw. Z.* **1922**, 513–22; *Japn. J. Med. Sci.* **2**, 22.—On pond-snails (*Viviparus malleatus* and *Viviparus japonicum*) H. estd. the amt. of glycogen in muscles, liver, digestive organs and ovary, and demonstrated in muscle exts. choline, a cryst. substance which corresponds to taurine and lactic acid. H. G.

Effect of the ambient p_H on the phototropism of marine pelagic copepods. MAURICE ROSE. *Arch. phys. biol.* **3**, 33–41 (1924); *Ber. ges. Physiol. expil. Pharmacol.* **30**, 375.

MARY JACOBSEN

The catalases in the first developmental stages of *Salmo Fario* (salmon trout). U. SAMMARTINO AND N. PETTINELLI. *Riv. biol.* **6**, 467–94 (1924); *Ber. ges. Physiol. expil. Pharmacol.* **30**, 483.—The catalase content of the eggs increases parallel with the development; the max. coincides with the absorption of the yolk sac. There is a subsequent decrease to a constant level. In devitalized eggs the catalase content falls to zero, provided that no bacterial action interferes. MARY JACOBSEN

The regulation of body volume in fresh water organisms. E. F. ADOLPH AND P. E. ADOLPH. *J. Expil. Zool.* **43**, 105–49 (1925).—Earthworms, frogs and flatworms show changes in body wt. when transferred from fresh water to various solns. In earthworms and flatworms water is lost to all solns; in frogs it is lost to hypotonic solns when they are nearly isotonic. Initial losses of water were often followed by adjustments in body water content. When returned to fresh water, the body vol. became approx. normal. In hypotonic chloride solns., almost no loss of Cl from the body occurred, but near isotonicity a slight intake of Cl may occur. Expts. with isolated frog skin showed that the integument alone ordinarily controls the passage of water and solutes. This

passage is not explained entirely by the principles of osmotic pressure. All quant. phenomena can be explained by assuming that electrostatic forces oppose osmotic ones. The body vol. of fresh water organisms is influenced by temp., the chem. nature of the body fluids, and of the medium, and other factors. The vol. is not const. as in the human, but definite means of adjustment exist, and the av. body vol. is characteristic.

CHAS. H. RICHARDSON

The role of aeration in the hatching of fertilized eggs of rotifers. J. C. LITE AND D. D. WHITNEY. *J. Exptl. Zool.* **43**, 1-9(1925).—Fertilized eggs of *Brachionus bakeri* develop normally in aerated water at room temp., but the young are unable to break through the egg membranes. If the newly laid fertilized eggs are sealed in containers with decompg. org. matter, the egg membranes are weakened and the young rotifers can readily break through. Such eggs hatch slowly or quickly according to the amt. of aeration of the water. Fertilized eggs of another species (*Asplanthna*) have a thick inner egg membrane which probably excludes the O_2 and causes the development of the young rotifers to cease. Abnormal fertilized eggs which lack this thick membrane may produce young females that may hatch inside the mother, or if laid, hatch soon after.

CHAS. H. RICHARDSON

Influencing the color changes in fish by means of chemicals. I. The effect of infundin and adrenaline on the melanophores and xanthophores of minnows (*Phoxinus laevis* Ag). LEO ABOLIN. *Anz. Akad. Wiss. Wien* **61**, 170-2(1924).—Over 200 specimens of minnows were injected with 0.05-0.15 cc. of 1:10 to 1:1000 solns. of adrenaline and infundin separately. An injection of 0.07 cc. of a 1:1000 soln. of adrenaline in the muscles of the back caused a typical contraction (max. in 8-10 min.) of the melanophores, the fish becoming very light yellow and remaining so for 2 hrs. The xanthophores are not affected. An injection of 0.08 cc. of an infundin soln. (1:100) caused a marked expansion of the melanophores in the lower layer of the skin and of the xanthophores in both layers. The fish becomes darker and the normally gray parts become pale yellow. A similar dose of 1:10 soln. caused an expansion of the xanthophores which, in some cases, masked the expansion of the melanophores. The effect of infundin was compared with other expansion-producing factors by the examn. of the skin of fish (1) which had been blinded; (2) had been kept over a black surface; and (3) which had suffered destruction of sympatheticus. In (1) a slight expansion of melanophores in the upper layer and localized expansion in the lower layer were observed; in (2) expansion occurred in the lower layer only, being similar to the action of infundin; (3) showed expansion in both layers, indicating a paralysis of the entire system. Whether these color changes are due to expansion of the cells or to an increase in color substance and what part the nervous system plays in this reaction is being investigated. **II. Production of male erythrophore coloring in female minnows (*Phoxinus laevis* Ag) by treatment with infundin.** *Ibid* 172-3.—The upper pigment layer of minnows contains varying nos. of erythrophores in the vicinity of the lips, fin bases and belly which are particularly prominent in the male when in a state of sexual excitation. By injection of 1:10 infundin soln. into an adult normal individual the erythrophores are expanded into star-shaped bodies which give the fish an intensive red color. A soln. 1:100 is less effective; one 1:1000 is without effect. The adult female, which normally does not show this vivid coloring, as well as the partly grown individuals of both sexes responds to the injection of infundin. Individuals of both sexes have an erythrophore system but normally it is stimulated only in the male at periods of sexual excitation.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

An examination of the errors introduced by the various approximate methods used for estimating the total quantities of milk and butter fat produced during a lactation. E. J. SHEEHY. *Sci. Proc. Roy. Dublin Soc. [N. S.]* **18**, 185-94(1926).—Daily records of butter fat and milk were kept on 8 cross-bred shorthorn cows. Calcs. were made by assuming weighings on one day each 1, 2, 3, 4, 5, or 6 weeks, the av. errors percent being, respectively, = 0.64, 1.44, 1.48, 2.37, 2.47 and 3.08. Four butterfat calcs. were made on assumed daily tests at intervals of 1, 2, 3, 4, 5 and 6 weeks, on 5 tests at regular intervals, 4 tests at irregular intervals and on tests two consecutive days at

6- and 7-week intervals. Av. percent errors were 3.16, 3.85, 4.64, 2.88, 2.88. For approx. methods Where fat tests have to be at long intervals, mill Results are on individual cows.

The subject "milk" in chemistry teaching. *chem. Unterricht* 38, 282-91(1925).—N. discusses a procedures as follows: % dry material; sepn. of ca microscopic examn.; approx. fat detn.; specific gravitation; detn. of reaction with litmus and phenolphthalein; methylene blue test for reductase which depends on bacterial content; H_2O_2 test for catalase; *p*-phenylenediamine and H_2O_2 test for oxidases; titrational acidity, showing how it is affected by fermentation. M. BEBER

The effect of freezing on the marketability of milk and cream. W. H. E. REED. *Milk Plant Monthly* 15, No. 1, 46(1926).—Freezing of milk and cream injures the flavor, and causes a decrease in the cream line of milk. H. F. ZOLLER

An investigation into the yield and composition of milk from the farm school dairy, Peradeniya. A. W. R. JOACHIM. *Trop. Agr.* (Ceylon) 65, 133-8(1925).—The av. fat content of milk from Scindi cows is 4.9%, of morning milk only 3.6 and of evening milk only 6.5%. When the diet remained the same there was on the av. an inverse relationship between the fat content and the yield and the fat content and hydrometer readings. The latter was almost quant. A. L. MEHRING

The phenomenon of rennet coagulation. A. DE DOMINICIS AND C. LA ROTONDA. *Ann. v. scuola agr. Portici* [2] 17, 1-20(1922).—From 75° on, the action of heat on milk is proportional to the temp. and the time of heating. The effect is to decrease and finally entirely to prevent the action of rennet. This fact is related to the modifications of a phys. character which casein undergoes; the particles tend to unite under the influence of heat into larger and more compact aggregates, thus passing into a state required for sepn. by coagulation, the phenomenon caused by the action of acids. In the presence of rennet, however, the casein does not modify its distribution but solidifies as in processes of gelatinization, the homogeneity of dispersion remaining perfectly preserved; the opposite effects to which the action of heat tends are, therefore, the reason of the unfavorable influence of the cooking of milk on its pptn. by rennet. Curd owes its ability to become fresh cheese to the property of its being in a gelatinous state different than that of the coagulated state. ALBERT R. MERZ

The food value of dried whey solids. J. B. ORR AND J. A. CRICHTON. *Scottish J. Agr.* 6, 63-7(1923).—The av. compn. of "fat-free" whey solids and lactalbumin produced at the government lactose factory at Crewe is: protein 12.0, 76.0; fat 1.0, 2.5; carbohydrates 69.0, 7.5; mineral matter 8.0, 3.0; and H_2O 10.0 and 11.0%, resp. Suckling pigs gained practically as much wt. over a period of 28 days when a mixt. of whey solids and lactalbumin was substituted for a portion of the sow milk as when whole milk was used, the total amt. of solids consumed being practically the same in both cases. Under similar conditions whey solids plus a meal mixt. was decidedly superior to the meal mixt. alone and only slightly less effective than skimmed milk plus meal mixt., the results being based on equiv. amts. of solid matter. Expts. with whey solids as a food for calves are in progress. The possibilities of using whey solids in compounding infant foods are pointed out. The annual production of whey in England is estd. at 100 million gallons, at least 50% of which is wasted. K. D. JACOB

Viscosity and whipping properties of milk and cream. J. C. HERRING AND A. C. DAHLBERG. *Milk Plant Monthly* 15, No. 3, 37(1926).—The viscosity of milk and cream increases with the percentage of fat irrespective of their treatment, providing the treatment was held uniform. The same general statement is true for whipping properties. Cream which has had its viscosity increased mechanically (by homogenization) whips in a shorter time but with less vol. Milk received at the station and immediately cooled to 37-40° F. by a tubular cooler until time of sepg at 90° F. always gave a cream of great viscosity. This indicated the probability that the clumping of the fat globules was largely responsible for the viscosity effect in cream. Expts. conducted with a MacMichael viscometer and a microscope substantiated this belief. H. F. Z.

Moisture in wheat and flour. M. L. THOMPSON. *Am. Miller* 54, 266(1926).—Moisture in flour is important because of its influence on keeping quality and because of its relation to the laws regarding net wt. In wheat high moisture content increases the rate of respiration of the grain which causes heating with its resulting damage to the flour produced from that wheat. The control of moisture in flour is not an easy matter, since it is influenced by (1) original moisture of the wheat, (2) vitreousness of the wheat, (3) amt. of water added in tempering, (4) length of temper, (5) atm. con-

Butter. S. KARPINSKY and J. S. ANDERSON. U. S. 1,574,821, March 2. Cream charged with air is formed into butter by forcing it through a narrow annular space between a rod and a closely spaced surrounding tube.

Margarine, etc. O. MUSTAD and SÖN. Brit. 237,242, July 16, 1924. Mixing of substances rich in vitamins with margarine or other edible fatty materials is carried out in CO_2 , N, H or other gas substantially free from O or air.

Fruit juices. W. S. PIERCE. Brit. 237,592, July 24, 1924. See U. S. 1,556,572 (C. A. 20, 79).

Apparatus for dehydrating fruit or similar materials. B. R. RAGAIN. U. S. 1,575,000, March 2.

Packing and preserving fruit. M. CARBONE. U. S. 1,575,148, March 2. A container is packed with grapes or other fruit and filled with juice of the same or a similar fruit, impregnated with a sterilizing agent such as SO_2 , and then sealed.

Devitalized yeast for use in making bread or other food products. C. HOFFMAN and C. N. FREY. U. S. 1,575,762, March 9. Yeast is treated with a satd. soln. of $(\text{NH}_4)_2\text{SO}_4$ or with a dil. acid soln., heated to about 85° , washed, filtered and dried without rupturing the cell walls.

Apparatus for dehydration of walnuts or other vegetable materials. C. C. MOORE. U. S. 1,574,994, March 2.

Preserving konjak powder. K. TAMANAHA. U. S. 1,574,638, Feb. 23. Konjak powder is mixed with about 5–10% of a substance of acid reaction such as salicylic acid or H_3BO_3 or treated with HCl gas or NaHSO_4 or other acid salt.

Curing cacao beans. W. B. McLAUGHLIN. U. S. 1,575,371, March 2. Cacao beans are maintained out of contact with air at a temp. (usually about 50 – 55°) above that at which organized ferments grow and below that at which the enzyme of the bean is injured, until the purplish red color of the bean changes to a reddish brown which upon drying becomes cinnamon brown.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Colloids in industry. P. M. TRAVIS. *J. Chem. Education* 3, 324–37(1926).

Progress in adsorption technic. R. KOETSCHAU. *Z. angew. Chem.* 39, 210–3 (1926).—See C. A. 20, 955.

Comparison of gas absorption and rectification. W. G. WHITMAN AND G. H. B. DAVIS. *Ind. Eng. Chem.* 18, 264–6(1926); cf. C. A. 19, 757.—The absorption of CO_2 from a gas mixt. by Na_2CO_3 – NaHCO_3 lye in a plate column can be adequately treated by the general absorption equation. The overall rate coeff. for absorption is proportional to the square root of the gas velocity through the column. The coeff. for absorption doubles with every 24° increase in temp. The same absorption equation governs the rate of rectification when steam and CO_2 are passed up through lye. The coeffs. in this case are about 2.4 times as great as those for absorption.

Ultra-purification of gas mixtures. J. A. ALMQUIST AND R. L. DODGE. *Chem. Met. Eng.* 33, 89–92(1926).—Gaseous contact catalyst poisons can be classified as (1) reversible or temporary poisons and (2) non-reversible or permanent poisons. Reversible poisons are those that inhibit the reaction only while present in the gas and from the effects of which the catalyst is able to recover when treated with pure gas. Typical poisons of this type for Fe NH_3 -catalysts include O, CO, and other O-contg. compds that are catalytically converted to H_2O in the presence of H. The non-reversible poisons are those that inhibit catalysis permanently, usually by reacting with the catalyst to form a compd. that is not readily removed by continued treatment with pure gas. S compds. and P may be classed as non-reversible poisons for reduced Fe catalysts. The distinction between the common reversible and non-reversible poisons is not a strict one, since poisons like S may become essentially reversible at high temps. if present in sufficiently small quantities. To avoid the deleterious effects of relatively small concns. of certain poisons, the gas may be submitted to ultra-purification. Suggested methods of removing small quantities of CO , CO_2 , S, halogens, P or H_2O from gases are listed. The methods are taken mostly from U. S. patent literature, and fall mainly in 2 classes: (1) absorption methods, comprising those in which the harmful impurities are retained by the purifying agent; (2) catalytic conversion methods, comprising those in which the harmful impurity is transformed into a harmless

one or into another deleterious impurity that can be more easily removed than the original poison.

R. L. DODGE

An investigation of crushing phenomena. A. M. GAUDIN. *Trans. Am. Inst. Mining Met. Eng.* No. 1565B, 58 pp. (Feb. 1926).—In structurally homogeneous rocks fracture takes place through grains and grain boundaries; in structurally heterogeneous rocks fracture passes in preference through grain boundaries. If a sized product, composed of homogeneous rock grains is crushed, a product results in which the relation between the percentage wt. of grains of various sizes and these sizes themselves follows a definite law. This is discussed for the *Dodge jaw crusher*, 4×7 in.; "*Krom*" rolls, 10×16 in.; *batch ball mill*, 8×10 in.; *batch rod mill*; and 20 in. continuous discharge *Hardinge ball mill*; quartz, *Stony Creek granite* and *galena* are used as materials. Sizing tests are represented graphically by the semi-logarithmic plot, in which the percentage of material retained by a screen and passing the next larger screen is plotted against the log of the screen aperture, and by the logarithmic plot, in which the log of the percentage of material retained is plotted against the log of the screen aperture. Typical size curves are shown for the various types of crushers, and are discussed mathematically for the different kinds and size of feed. Photographs are shown of quartz grains crushed in rolls. The difference in shape is ascribed to the combination of the sorting actions of the screens and the rolls, which are different. It is concluded that rolls crush by breaking through the particle as contrasted with surface wear. The action of a jaw crusher is substantially the same as that of rolls. The action of pebble mills without pebbles is distinctly rounding, the amt. of the material ground off varying substantially as the square of the grain diameters, and showing a diameter of less than 10 microns. In the rod mill the fine grains are of the same shape as those produced by rolls, but the coarser grains tend to be equidimensional. An increase in the no. of rods from 4 to 16 increases the grinding work 20 times. In this type of mill, grinding is done by breaking through the grain. The straight-line relation between the log of the percentage corresponding to a certain range in size and the log of that size which was found to hold for jaw crusher, crushing rolls and rod mill holds for ball milling only when the ratio of size of feed to size of balls is below a certain *critical ratio*. When it is above that ratio, the balls appear to grind grains of intermediate size, chipping off sharp edges from the larger grains and eventually rounding these without pulverizing them. With $7/8$ to 1 in. balls, the critical size is about 2 mm., and with balls twice that size, the critical size is 4.6 mm. The size of *preponderant breaking* is of the order of $1/1000$ of the ball diameter. The relation $y = Cx^k$, in which $y = \%$ of material, x = screen aperture, C = a const., and k = the slope of the straight line in the logarithmic plot, holds for the fine range of roll, jaw crusher and rod mill product under all conditions tested, but for the ball mill product only under certain conditions. The computation of *specific surface*, size of *av. surface*, size of *av. vol.*, and no. of particles is derived in detail. In studying heterogeneous rocks, *Manhattan schist* and *Inwood limestone* are used. The logarithmic size curve obtained from sized feed is not a straight line as with homogeneous material. A larger percentage of rock breaks at the av. grain size in the heterogeneous rocks.

H. STOERTZ

New method of conducting filtration tests. D. R. SPERRY. *Ind. Eng. Chem.* 18, 276-9 (1926).—A recording device for time discharge and time pressure curves is described.

L. A. PRIDGEON

A new principle of heat exchange: the jet system. R. HERTWECK. *Wärme & Kälte Tech.* 27, 234-6 (1925).—Where one fluid is to take up heat from another through a wall (e. g., of a pipe), the rate of heat transfer may be much increased by admitting one or both of the fluids to the wall through orifices in an outer jacket (or inner pipe). In this way the fluid impinges on all parts of the surface in a series of jets, instead of merely flowing along it. The size and cost of equipment are thereby much reduced. The system has been applied to condensers and air and water heaters, and the tests given indicate that the coeff. of heat transfer can be increased several fold.

E. W. T.

Distribution of energy. R. F. STARKE. *Feuerungstechnik* 13, 145-6 (1925).—S. compares the cost of distributing one energy unit as gas, as elec. current and as coal, over different distances and under various conditions. For long distances (100-200 kilometers) gas has the lowest costs.

ERNEST W. THIBLE

Organic insulating materials. A. C. HOPPER. *Electrician* 96, 258-9 (1926).—An outline of: the properties of an ideal insulating material, the effect of increasing voltages, impregnating problems and the question of acidity. Moisture effects, air bubble phenomena, and the desirability of substituting fish oil for linseed oil when prolonged exposure to high temps. is anticipated are discussed. It is claimed (U. S. pat. 1,091,621) that cambric treated with an insulating material consisting of a mixt.

of phenol-formaldehyde resin and stearin pitch in AmOAc soln. retains its flexibility far longer than a linseed oil varnish and maintains its resistivity and in some cases actually increases its resistance with rise of temp. The coated fabric showed increased resistance up to 70°. "Metallized" C filament is the only other known substance having a plus temp. coeff. With a "flushed" filament, the hot resistance approximates $1/2$ the cold resistance; after elec. furnace treatment it is 2.6 times the cold resistance.

A high-frequency voltage test for insulation. J. L. RYLANDER. *J. Am. Inst. Elec. Eng.* 45, 217-21(1926). C. G. F.

Theory of absorption in solid dielectrics. VLADIMAR KARPETOFF. *J. Am. Inst. Elec. Eng.* 45, 236-40(1926). C. G. F.

The rescue apparatus, its physiological action on the rescue worker, and its purpose. J. BIALEK. *Montan. Rundschau* 17, 673-82(1925).—A review tracing the development of gas masks used by rescue workers in mines. M. BEBER

The rescue apparatus, its physiological action on the rescue worker, and its purpose. J. BIALEK. *Montan. Rundschau* 17, 703-7(1925); (cf. preceding abstr.).—Increase in CO₂ and decrease in O₂ in the app. exhaust the rescue worker more quickly. If the CO₂ content remains within certain limits (1%) and if air is rich in O₂ (more than 21%), no untoward effects result. Breathing pure O₂ has no ill effects, but is beneficial if the blood has a higher than normal CO₂ content, in that it aids in a more effective gas exchange. O₂ deficiency is much more serious. The rescue worker breathes into a space of higher pressure and from a space of lowered pressure: chest muscles do 41 kg. more work with each inhalation and 17.5 kg. with each exhalation. Useful work is decreased by these amts. Values will vary with the individual and with the app. Gas must be cooled after purification: various methods are given. Essentials of the rescue app. are: (1) it must furnish the wearer with enough air for his activities; (2) it must be air tight; and (3) hinder the rescue worker the least in the carrying out of his duties. The purposes are: (1) to permit rescue workers to go into unbreathable atm. and save people there and (2) to do away with the results of an explosion and bring the mine back to its original condition as quickly as possible. Cooling, liquefaction and separation of constituents of gases. A. SELIGMANN. U. S. 1,573,752, Feb. 16. In low-temp. cooling, liquefaction and sepn. of gases by throttling, the major portion of the decrease of pressure is induced by causing the gases to flow at relatively great velocity through pipes in which friction of the gases occurs throughout the length of the pipe walls such as to "consume" the decrease in pressure.

Magnetic treatment system for separation of constituents of liquid air or other fluid mixtures. P. E. HAYNES. U. S. 1,575,587, March 2.

Heat exchange and expansion system for liquefaction and separation of constituents of air or other gases. A. SELIGMANN. U. S. 1,574,119, Feb. 23.

Heat-exchange system for liquefaction and rectification of air or other gaseous mixtures. F. JORDAN. U. S. 1,574,425, Feb. 23.

Gravity and centrifugal separation of constituents of gas and vapor mixtures. S. P. SZCZEPANOWSKI. Brit. 237,617, July 22, 1924.

Protecting gas-absorbing substances from penetration by liquids. R. OPPENHEIM.

U. S. 1,574,844, March 2. Battery elements or other porous articles are covered with a pectized colloid in sheet form such as cellophane. U. S. 1,574,845 specifies tubular porous battery elements rendered impermeable to liquid while remaining permeable to gases, so as to act as a dialyzer.

Disintegrating talc, iron oxide or other dry materials. H. PLAUSON. U. S. 1,575,717, March 9. The material is subjected to impact against moving parts rotated at a relative velocity of at least 1000 revolutions per min. and in which the peripheral speed is at least 1000 meters per min., the operation being carried out *in vacuo*.

Heating petroleum or other fluids. F. E. WELLMAN. U. S. 1,573,591, Feb. 16. A mass of sand or other granular refractory material is heated and is then permitted to flow over and around vertical tubes or other containers holding petroleum oil which is being cracked or other fluid to be heated.

Heat- and electric-insulation. N. STABILE. Brit. 237,507, Feb. 2, 1925. A molded material is formed from ground leather 65, resin 20, Zn salts, oxide or carbonate 8 and inert fillers such as ground stone or sand 7%.

Electric insulation. G. F. DREHER. U. S. 1,574,562, Feb. 23. An asbestos compn. is impregnated with still wax which is modified by distn. to produce a flow point of about 45–50° and then applied to the compn. at a temp. of about 220°.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Modern British practice in water softening. V. Zeolite or base-exchange methods of water softening. D. BROWNLIE. *Ind. Chemist* 2, 61–4(1926); cf. C. A. 20, 637.—The advantages of the zeolite species of water softener (doulcil, kenzelite, permute) are: (1) zero hardness, (2) ease of dealing with all qualities of H₂O, (3) no sludge, (4) simplicity of plant, (5) operation under pressure, (6) small floor space, (7) no moving parts, (8) alkali beneficial in boiler water and for laundry and bleaching plants, (9) easy control of exact hardness. Disadvantages are: (1) Alk. water is a cause of foaming and priming, and at pressures above 150 lbs. per sq. in. tends to render boiler plate brittle. Such water is objectionable for drinking and cooking, also in dyeing, brewing and other fermentation processes. (2) The zeolite disintegrates (3) CO₂ exerts solvent action on the zeolite. (4) Acids act on the zeolite. (5) Iron in the water ppts. as Fe(OH)₃ and lessens the effectiveness and rate of regeneration of the zeolite. (6) Traces of oil in the water gradually cover the zeolite with a fine film and render it useless. (7) Mud and suspended matter must first be removed. (8) Size of plant depends on the hardness of the water. (9) There is nothing to prevent unsoftened water passing through when the bed is exhausted. (10) Zero hardness is not necessary since 1° or 2° of hardness does not cause pptn. of the Mg and Ca salts of the fatty acids. These remain in soln. and act as detergents. The whole subject is, however, bristling with conflicting opinions and claims. In general, zeolite methods are ideal for water of moderate hardness, not over 12°–15° total with little or no temporary hardness. For a very hard water with little permanent hardness the CaO-Na₂CO₃ method is infinitely superior.

E. G. R. ARDAGH

Problems of hard and soft water. R. A. THUMA. *J. Am. Water Works Assoc.* 15, 152–7(1926).—Softening a water will save soap, fuel, and, in municipal filtration, Cl, reduce corrosion and boiler up-keep.

D. K. FRENCH

Note on the determination of permanent hardness of water by Pfeifer and Wartha's method. ARTHUR LUMSDEN-BEDINGFELD. *J. Soc. Chem. Ind.* 45, 36T(1926).—In the P. and W. modification of the Hehner method of detg. permanent hardness, standard NaOH is used with Na₂CO₃, the water concd. to half vol., the Ca and Mg carbonates are filtered off and the filtrate is titrated. Results by this method are too high because of absorption of NaOH by the filter paper, a 9-cm. filter paper absorbing 0.04 cc. 0.2 N NaOH which could not be washed out with cold water. The modification is held to have no advantage over the original method.

BEN H. PETERSON

Carbonates and bicarbonates in the water of the Nile. V. M. MOSSÉRI. *Bull. inst. Egypte* 7, 155–62(1925).—The alk. to phenolphthalein due to carbonates and also alk. silicates is appreciable (6–11 mg. CO₃ per l.) in May, June and July, the last 3 months of low water; the rest of the year it is slight or hardly perceptible. Bicarbonates are present all the year, the concn., expressed as mg. HCO₃ per l., varying from 98 to 159, with a max. in June and July and a min. in September to December. In equivalents of CO₃ the carbonates (and alk. silicates) represent 0.0–5.5% of the total sol. matter; while the bicarbonates represent 35–44%. The sum of the two ranges from

36 to 45% of the total sol. material, but during the greater part of the year the range is about 40-45%.

P. R. DAWSON

Chemical and chemico-physical researches on the saline water of S. Venera (Acireale) which contains bicarbonates, hydrosulfides, boric acid, bromine, iodine and lithium. R. NASINI, C. PORLEZZA AND A. DONATI. *Ann. chim. applicata* 15, 484-518(1925).—Extensive analyses indicated that the % compn. of the water was approx. the following in mg. per l.: Na 1455.5, K 5.3, Li 0.3, NH_4 19.7, Mg 92.1, Ca 62.3, Sr 5.7, Ba 0.8, Fe (ferric) 0.2, Al 0.2, Cl 2311.5, Br 5.6, I 2.9, SO_4 97.2, HPO_4 0.5, HCO_3 450.7, HS 23.4, NaCl 522.1, Na_2SO_4 60.2, NaHCO_3 123.5, NaHS 5.2, KCl 0.5, K_2SO_4 0.1, KHCO_3 0.1, KHS 0.01, NH_4Cl 3.1, $(\text{NH}_4)_2\text{SO}_4$ 0.4, NH_4HCO_3 0.7, NH_4HS 0.03, MgCl_2 179.0, MgSO_4 21.5, $\text{Mg}(\text{HCO}_3)_2$ 45.3, $\text{Mg}(\text{HS})_2$ 1.8, CaCl_2 70.7, CaSO_4 8.2, $\text{Ca}(\text{HCO}_3)_2$ 17.0, $\text{Ca}(\text{HS})_2$ 0.7, SrCl_2 4.5, SrSO_4 0.5, $\text{Sr}(\text{HCO}_3)_2$ 1.0, $\text{Sr}(\text{HS})_2$ 0.05, SiO_2 39.0, free CO_2 213.0, H_2S 48.5, free H_3BO_3 2.1. Its radioactivity (0.6981 Maché units per l.), its osmotic pressure and certain of the mineral components such as H_3BO_3 impart to the water therapeutic properties which may account for its present high reputation and which should render it of increasing importance.

C. C. DAVIS

Chemical analysis of Capvern water. CH. LORMAND. *Compt. rend.* 182, 404-6 (1926).—This thermal water of Triassic origin gave the following figures: temp. 23.8° (temp. of the air 7°), resistivity 496.5, $\Delta -0.30$, p_{H} 8.0, radioactivity in millimicrocuries per l. 0.405, Ra dissolved $10^{-12} \times 17.7$, residue at 100° 1.9685, residue at dull red heat 1.5406. *Cations:* K 0.00209, Na 0.00983, Li 0.00003, Mg 0.09325, Ca 0.35460, Sr trace, Ra $10^{-12} \times 17.7$, Fe 0.00081, Mn 0.000004, Cu trace. *Anions:* Cl 0.00497, Br trace, S as SO_3 0.86791, Si as SiO_2 0.01052, C as CO_2 0.06830, N as HNO_3 0.00130, hororadioactivity in microcuries 29.3625, radioactive power in mg. of Ra 3.91.

L. W. RIGGS

Water treatment in Ohio. W. H. DITTOE. *J. Am. Water Works Assoc.* 15, 137-41 (1926).—A general study of the condition of water works equipment and operation in 1908 has resulted in the adoption of methods to insure their efficiency.

D. K. FRENCH

Stream pollution. KENNETH ALLEN. *Proc. Am. Soc. Civil Eng.* 52, 520-31 (1926).—A symposium of the results of the Metropolitan Sewerage Commission from 1909 to 1924. Dissolved- O_2 tests are the best criteria of stream pollution. Comparative results show loss of dissolved O_2 as % satn. from 1909 to 1924; at East River, 57 to 14%; Hudson River at 42nd street, 65 to 22%; Morris Heights, Harlem River, 46 to 10%; Upper Bay, 60 to 28%. The vol. of sewage entering New York Harbor is approx. 2,060,000,000 gals. daily. The biochem. demand in the Harbor is estd. at 1,558,700 lbs. daily. A standard of cleanness is proposed: (1) Solid matter recognizable as of sewage origin shall not be visible in the Harbor. (2) Marked coloration, turbidity, effervescence, oil odor or deposits due to sewage shall not occur except in the immediate vicinity of the outlet. (3) Discharge of sewage shall not contribute materially to the formation of deposits injurious to health or navigation. (4) Quality of water at all points suitable for bathing or oyster culture shall conform to the bacteriological purity of drinking water. Activated-sludge plants are contemplated at Wards Island and south of Jamaica Bay. For the other localities fine screening and chlorination will suffice.

BEN H. PETERSON

Water analysis, dissolved oxygen by Winkler method. E. J. THERIAULT. *U. S. Public Health Bull.* 151, 43 pp.(1925).—The Winkler method with the Rideal-Stewart modification was used in an extensive stream pollution investigation. The various modifications that are necessary in the presence of nitrites, iron salts, and easily oxidized org. matter are discussed in some detail. Complete absorption of dissolved O_2 is assured by causing the ppt. of Mn hydroxides to settle a second time. Loss of iodine by volatilization is prevented by titration in the sample bottle itself, and by the use of large ams. of iodide. The KMnO_4 treatment is fully effective in counteracting the interference due to such forms of org. matter that are commonly present in fresh sewage or recently collected industrial wastes. The KMnO_4 modification should give accurate results in the presence of iron salts up to 100 p. p. m. If 2 cc. 40% $\text{KF} \cdot 2\text{H}_2\text{O}$ are added to a 300-cc. sample of the iron salt delay of decolorization of KMnO_4 by oxalates is greatly diminished. When the delay before titration is protracted, 4 cc. 85% H_3PO_4 in 300-cc. sample should be substituted for the usual H_2SO_4 .

C. M. SALLS

The presence of iodates in well-water. C. F. HICKETHIER AND ALBERTO JACOBUECCI. *Z. anal. Chem.* 67, 129-33(1925).—In the examn. of some waters from the Argentine Republic, the presence of nitrites was indicated by testing with Trommsdorff's reagent but subsequent investigation showed that the test was due to iodates. This indicates that residues of an ocean remain from the tertiary period. The reactions of Ilosvay

v. Ilosva and of Riegler are the most reliable and most sensitive tests that are available
HNO₂. W. T. H.

Nitrate determinations. G. W. BURKE. *J. Am. Water Works Assoc.* 15, 169-70 (1926).—Where the presence of org. matter interferes with color comparisons the reduction method is recommended. D. K. FRENCH

In what chemical form does silicic acid exist in water? W. WINDISCH. *Woch. Brau.* 42, 59(1925).—A siliceous H₂O contg. 34.5 parts carbonates per 100,000 of which 22.5 were Na₂CO₃ was subjected to electroösmosis and after the treatment contained only 1 part alk. earth carbonates and 2.5 Na₂CO₃. The N₂O₅ content was reduced from 4.21 to 0.18. The silica content remained unchanged indicating that Si is present as SiO₂ and not as silicate. A good brewing H₂O can be made from hard H₂O by means of electroösmosis. C. N. FREY

Report of advisory committee on official water standards. U. S. Publ. Health Rept. 40, 693-722(1925).—The text of the proposed U. S. Treasury Dept. standard regarding (1) source and protection, (2) bacteriol. quality and (3) phys. and chem. characteristics is given and discussed. The recommended limits for phys. and chem. quality are as follows, in p. p. m.: turbidity 10 (in general not more than 5), color 20 (preferably less than 10), Pb 0.1, Cu 0.2, Zn 5.0, sulfate 250, Mg 100, total solids 1000, chloride 250, Fe 0.3, and carbonates of Na and K expressed as Ca carbonate 50. The supply shall be rejected if Pb, Cu or Zn is present in excess of the amts. specified, but not for failure to conform to the other chem. and phys. requirements unless another more suitable supply is readily available. The bacteriol. standard has been described previously (cf. Jordan, C. A. 19, 2247). A mathematical discussion of the *B. coli* test by L. J. Reed is appended, in which probable *B. coli* densities for various types of samples, using both 5 portions, of 10 cc. each, and portions in geometric series, are shown graphically. B. C. A.

Composition of imported bottled waters. A. E. MIX AND J. W. SALE. *J. Am. Med. Assoc.* 85, 1963-7(1925).—Both imported and domestic waters are classified under their predominating mineral constituents as follows: dolomitic limestone, Vichy type, NaHCO₃, NaCl, MgSO₄ or Na₂SO₄ or both, and the Fe type. Over 250 imported waters were analyzed and classified according to the above scheme. L. W. RIGGS

Colon bacteria in some fissure springs of the Balcones Fault zone. I. M. LEWIS. *J. Am. Water Works Assoc.* 15, 158-68(1926).—While colon bacteria are found in such water, the nature of the catchment area indicates animal rather than human feces responsible. The colon bacteria being of the Escherichia type are not considered of great sanitary importance. D. K. FRENCH

The use of quinic acid in the differentiation of the colon-aerogenes groups. B. H. BUTCHER. *J. Am. Water Works Assoc.* 15, 171-3(1926).—This reagent is considered a valuable one to be used in species identification in the colon-aerogenes group. A formula for prepn. is given. D. K. FRENCH

Equations for determination of pressure drop in water mains. PAUL BRINKHAUS. *Gas u. Wasserfach* 69, 165-8(1926).—Equations, tabulations and charts are given. W. B. PLUMMER

The hydroelectric plants of Rempen and Sieben in the canton of Schwyz, Switzerland. The barrage reservoir of Wägital. A. BIDAULT DES CHAUMES. *Genie civil* 87, 241-5(1925).—The most important development in Switzerland. The reservoir will contain 148 million cu. m. retained by a dam 100 m. high. The fall utilized is 240-260 m. at Rempen. At this point there is a 368,000 cu. m. basin from which the water passes to the Sieben plant after a fall of 190-195 m. The final discharge to the lake of Zurich is by the original bed of the river Aa. JACK J. HINMAN, JR.

Eliminating boiler scale by the Agfil process. D. A. GARDNER. *Power* 63, 261-2 (1926).—A small pulsating d. c. is passed over the inside surface of the boiler. The result is the pptn. of the scale-forming material as a sludge. No theoretical explanation has been advanced. The process has been used in Europe for 3 years. A recent installation in this country is illustrated. D. B. DILL

Relation between stream pollution and extent of sewage treatment required. J. K. HOSKINS. *Proc. Am. Soc. Munic. Improvements* 31, 317.—Point of max. concn. of *B. coli* occurs 10 to 15 hrs. in summer and 15 to 30 hrs. in winter below the sewer outlet. Bacterial decrease is more rapid in summer than in winter. It is possible by knowing the max. concn. to predict the no. of *B. coli* remaining in a stream at stated intervals of time and distance from the sewer outlet. Permissible limits of *B. coli* in raw water to be purified are 1000 to 1200 per cc. The *B. coli* per cc. permissible at max. concn. can be then calcd., considering the time of flow from point of contamination to water plant. BEN H. PETERSON

Military sanitation. ANON. *Army Med. Bull.* No. 15, 1925; *Pub. Health Eng. Abstracts*, Jan. 9, 1926. *Water*.—Military needs for water are discussed, with detailed methods of mobile water purification and sterilization equipment. M. E. F.

Industrial wastes as fertilizer (REGE) 15. Spectrographic analyses of residues of mineral waters (I) water of Salsomaggiore (PORLEZZA, DONATI) 7. Evaporating apparatus for concentrating or drying sewage (U. S. pat. 1,576,471) 1.

Purifying water by use of barium silicate (to remove hardness). A. L. GRANT. U. S. 1,574,477, Feb. 23.

Apparatus for purifying water by ozone. H. B. HARTMAN. U. S. 1,574,389, Feb. 23.

Regenerating water of aquaria. E. W. BETH. U. S. 1,574,783, March 2. Mech. features of raising H_2O by compressed air, sepn. of vitiated air and CO_2 and return flow of the H_2O .

Removal of oil from boiler feed water. J. C. DIJXHOORN. Dutch 14,335, Feb. 15, 1926. Filtration of the oil contg. feed water through a filter press provided with a thin layer of $Al(OH)_3$ (either directly applied or added to the water) removes the finely emulsified oil completely.

Treating garbage. J. T. FETHERSTON. U. S. 1,576,105, March 9. A mixt. of NaCl with a small proportion of an acid-neutralizing substance such as CaO is used for retarding decompn. U. S. 1,576,106 specifies sprinkling salt on the bottom and sides of garbage containers to reduce objectionable odors.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

The loess of China. G. B. BARBOUR. *China J. Science & Arts* 3, 454-63, 509-19 (1925).—Chem. analysis gives figures not greatly different from those for ordinary silt loam, and the peculiar characteristics of loess would seem to have a phys. rather than a chem. basis. Mineralogical analysis indicates the presence of minerals predominating in unweathered granitic rocks, which is sited as evidence in favor of the wind action theory of loess formation. WM. H. ADOLPH

Formation and decomposition of humus in the soil. R. BALKS. *Landw. Vers. Sta.* 103, 221-58(1925).—In general, the amt. of chemically bound water is correlated with the clay and silica content of the soil. The catalytic power of the soil is conditioned by the presence of enzymes and colloids. Total N, easily sol. N, carbohydrates, pentosans, sugars and methoxyls were detd. before and after fertilizing. F. M. SCHERTZ

The methods of estimating the absorption capacity and the condition of unsaturation of soils. E. V. BOBKO AND D. L. ASKINAZI. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 25, 1-42.—The method used in detg. the absorption capacity has to be in accord with following conditions: (1) the neutral salt used must be of a nature easy to est. analytically; (2) it must not be present in the soil; (3) it must be very active in replacing bases; (4) it must not act destructively upon the absorbing complex of the soil. $BaCl_2$ meets the requirements. A procedure is also given in case $CaCO_3$ or $CaSO_4$ is found in the soil. An English summary is given. J. S. JOFFE

The influence of available nitrogen on the fermentation of cellulose in the soil. J. A. ANDERSON. *Soil Science* 21, 115-26(1926); cf. C. A. 20, 257.—The rate of cellulose decompn. in the soil increases with the increase in available N until the latter is present in amts. necessary for optimum growth. This point was reached with a ratio of N:cellulose of about 1:35. Further addn. of N was without effect. The amt. of cellulose fermented per mg. of N utilized was not const. but decreased rapidly with increases in the N available. Nitrification proceeded normally in the cellulose-treated soils but the NO_3 formed was immediately utilized by the cellulose organisms. NH_4 can serve as a direct source of N for these organisms. None of the soil processes is inhibited by the addn. of carbohydrates to the soil. Crop failures in such cases are due to the inability of the crop successfully to compete with the microorganisms for the limited amt. of N available. N present in crop residues is as readily available to organisms as a source of N as is NH_3 after their protein is hydrolyzed to the amino acid stage. R. BRADFELD

Nitrogen recuperation in the soils of the Bombay Deccan. I. D. L. SAHASRABUDDHE AND J. A. DAJI. *Mem. Dept. Agr. India Chem. Ser.* 8, 53-68(1925).—When

water is added to the soil, within 10 days a large quantity of N is fixed. This increases for about 35 days and then slowly decreases. Up to 30% H₂O, the larger the quantity of H₂O the more N is fixed. Fixation of N and nitrification are higher at 40° than at lower temps. Increase in N takes place both in the presence and absence of light. The addn. of lime to the soil does not show any increase over the original soil in increasing N fixation, but it facilitates nitrification. If a soil which has fixed the highest quantity of N after being moistened dries up and then becomes moist again, the N increases further for 4 or 5 weeks and then decreases. The soil loses a small quantity of N when heated to 100°. This loss is quickly recovered if sufficient H₂O is added to the soil. The total N fixed in the heated soil is greater than that in the unheated soil.

RUSSELL M. JONES

The relation of the denitrification process to the reaction of the medium. T. M. ZACHAROVA. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 15, 1-22.—The decompn. of nitrates by bacteria Van Iterson is stimulated at the reaction corresponding to the p_H range 7.0-8.2; at 6.1 and 6.4 the process is slow. The limits of denitrification are p_H 5.5 on the acid side and 9.8 on the alk. The decompn. of nitrates is more energetic at p_H 5.5-7.0. Sr(NO₃)₂ is a better source of N for the study as it produces less alky. than KNO₃.

J. S. JOFFE

Denitrification and reaction of the medium in relation to the liming of the soil. T. M. ZACHAROVA. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 29, 1-20; cf. preceding abstract.—Lime application increases the number of denitrifying bacteria in the soil. An English summary is given.

J. S. JOFFE

The ammonia content of soil, and its relation to total nitrogen, nitrates and soil reaction. H. J. HARPER. *J. Agr. Research* 31, 549-53 (1925).—A detn. of acidity and of the total NH₃ and nitrate N occurring in 45 soils showed that there is no correlation between the NH₃ content of soils, total N, nitrate content and soil reaction. The NH₃ content of a soil is evidently in equil. with the products of protein hydrolysis and nitrification just as the nitrate content is in equil. with the NH₃ content of the soil and the plants and microorganisms. The NH₃ content of field soils may occasionally run as high as 70 p. p. m., but the NH₃ occurring in most soils does not exceed 20 p. p. m. and the majority of soils contain less than 10 p. p. m.

W. H. ROSS

Annual report of the agricultural chemist to Punjab government for the year ending 30th June, 1924. P. E. LANDER. *Rept. Operations Dept. Agr., Punjab* 2, Part 2, 37-54 (1925); cf. C. A. 19, 2718.—Analyses of representative samples of Punjab soils and agricultural products displayed at the British Empire Exhibition are tabulated as follows: *Punjab soils*. Chem. and mech. analyses together with the kind of crop usually grown are given for 39 soils from 16 localities. *Oil seeds*. The H₂O and oil content of rape (Japan black and Japan white), desi rai, mustard No. 1, castor, cotton seed (4-F and Mollisoni), toria, safflower, yellow rape, sarson and taramira seed are given. *Oil cakes*. The H₂O, ash, fat, crude fiber, albuminoid and sol. carbohydrate content are given for castor, sarson, black sesame, toria and taramira cake. *Oils*. The sp. gr., viscosity, and acid, sapon., Hehner, R.-M. and I values are given for sarson, toria, linseed, mahua, taramira, sesame, cotton-seed (American and Desi), yellow rape, castor, desi rai, and safflower oil. *Wheats*. The H₂O, ash, N, fat and fiber contents of 10 varieties of Punjab wheats are given. *Grams, barleys and pulses*. The H₂O, fat, ash, crude fiber, albuminoid and sol. carbohydrate contents are given for 9 varieties of Punjab grams, 6 varieties of barleys, and lentils, peas, wild peas and masha masur. *Sugar cane and sugar products*. Seasonal analyses of 23 varieties of sugar cane, and the glucose and sucrose content of sugar cane products known locally as gur, shakkar, khand, rab and shira are tabulated. Figures are given for the glucose and sucrose content of gurs from 10 types of cane grown in 8 districts of the United Provinces. Data are given on the use of sewage H₂O as a fertilizer (cf. C. A. 20, 86). Attempts to isolate bacteria-free cultures of protozoa from soils were unsuccessful. *Azotobacter* was easily and rapidly isolated from 3 different soils by inoculating into Ashby's manitol soln. and after 2 days (before formation of scum on the soln.) prepg. soil plates from the flasks with a mannitol agar according to Burgess (Soil Laboratory Manual p. 94). Growth was very rapid and satisfactory. Close examn. showed that the cultures were pure. Ashby's mannitol agar did not give good growth. K. D. JACOB

The problems and proceedings of agricultural microbiology. E. E. USPENSKII. *Trans. Inst. Fertilizers (Moscow)* 1923, No. 17, 1-10.—A theoretical discussion of a scientific program of soil microbiological research; special emphasis is given to the study of *Azotobacter*, denitrifiers and organisms decomp. org. matter.

J. S. JOFFE

Method of counting soil bacteria according to their physiological groupings. S. RAZOUMOV. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 28, 1-20.—A report of a

study on the detn. of various physiol. groups of bacteria in soil with the aid of elective media following the technic of Hiltner and Störmer. R. also discusses the effect of lime on the various groups. J. S. JOFFE

A comparative study of the bacterial flora of wind-blown soil. I. Arroyo Bank soil, Tucson, Arizona. I. M. SNOW. *Soil Science* 21, 143-65(1926).—A study was made of the aerobic microorganisms growing on an arid sandy soil with p_H values of 8.6-9.0 according to the depth. The surface 6-inch layer was driest, most alk. and the least favorable for bacteria. The nos. of bacteria per g. of fresh soil were: 6 in., 401,000; 12 in., 1,898,500; 24 in., 916,500. Of the total no. of colonies of all depths 52.4% were actinomycetes, 0.77 filamentous fungi, and 46.81% yeasts and bacteria. The actinomycetes were more numerous at 24 in. than at 6 in. Pure cultures were isolated and studied morphologically and culturally. Morphologically, 24% were cocci, 20.4% short non-spore-bearing rods, 13% long non-spore-bearing rods, and 42.6% long spore-bearing rods, 64.8% were Gram-negative. Culturally, 135.3% fermented glucose; 28.5% fermented sucrose; only one form fermented lactose; 70.4% digested gelatin, and 56.5% casein while 32.6% reduced nitrates to nitrites. R. BRADFIELD

Some questions in the oxidation of elementary sulfur. ANON. *Centr. Bakt. Parasitenk. II Abt.* 62, 290-5(1924).—The oxidation of elementary S in soil is almost exclusively biol. in nature. A long series of aerobic bacteria participate which are not ordinarily considered S bacteria. Most aerobes possess this power under favorable conditions. Such common molds as *Aspergillus niger* and *Oidium albicans* may oxidize S. JOHN T. MYERS

Fixation of nitrogen and radioactivity. E. KAYSER. *Compt. rend. agr. France* 11, 716-9(1925).—The addn. of radioactive mineral increased the fixation of N in proportions variable with the species used. F. M. SCHERTZ

Microbiology of soil in relation to liming and phosphorus applications. E. F. USPENSKII. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 34, 65-71.—A discussion of the relation of lime and P in a rational program of soil microbiological research is presented. J. S. JOFFE

The use of standard soils with the potassium thiocyanate test for estimating lime requirement of soils. A. F. GUSTAFSON. *J. Am. Soc. Agron.* 16, 772-6(1924); *Expt. Sta. Record* 53, 120-1.—The advantages of using standard soils instead of a color chart for estg. the quantity of lime needed per acre by red clover, alfalfa or sweet clover are briefly outlined. The use of standard soils is said to have the distinct advantage that the lime requirements of soils for clover can be estd. at any time after settling has occurred during a period of 24 hrs. H. G.

Soil acidity and the use of lime on tea soils. P. H. CARPENTER, H. R. COOPER AND C. R. HARLER. *Quart. J. Indian Tea Assoc.* Part 1, (1925); *Trop. Agr. (Ceylon)* 65, 150-6(1925).—Tea grows well only in soils which are definitely acid. Application of CaO in different forms and combinations with other fertilizers reduced the yields in every case, even when applied as neutral $CaSO_4$. CaO can be applied with benefit only when the soil is excessively heavy and excessively acid. A. L. MEHRING

Comparison of methods for determining the hydrogen-ion concentration of soils. H. NIKLAS AND A. HOCK. *Landw. Vers. Sta.* 104, 87-91(1925).—A tabulated comparison between Clark's and Michaelis's colorimetric methods and the electrometric method is presented. F. M. SCHERTZ

Significance of the electrometric titration in determining the lime requirement of soils. H. NIKLAS AND A. HOCK. *Landw. Vers. Sta.* 104, 93-102(1925).—From 2 curves the authors are able to calc. the amt. of lime or acid necessary to bring the soil to a desired reaction. F. M. SCHERTZ

Lime and phosphoric acid in soil. M. A. EGOROV. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 34, 37-43.—This is a discussion of the influence of various forms of soil Ca on the phosphate in the chernozem district. J. S. JOFFE

The absorption of phosphoric acid by soils. V. V. GEMMERLING. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 34, 46-50.—Most of the P_2O_5 in soils, red and podsol, is not in the form of Ca salts but in combination with Fe and Al oxides; in chernozem part of the P_2O_5 is in combination with Ca. J. S. JOFFE

Lime applications. D. N. PRIANISHNIKOV. *Trans. Inst. Fertilizers (Moscow)* 1925, 51-3.—This is a theoretical discussion of the benefits and injurious effects of lime. J. S. JOFFE

The injurious effects of excessive liming on podsol soils. A. F. TYULIN. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 26, 1-43.—This is a continuation of the expts reported in *C. A.* 20, 1296. An extensive summary of the results is given in English. J. S. JOFFE

The action of lime in the soil and the effects on the crop. D. DRUZHININ. *Trans. Inst. Fertilizers* (Moscow) 1923, No. 20, 1-22.—Acidity and absorption capacity of soils are closely related. The lime additions which give the highest yield increases do not correspond to the lime requirements necessary to neutralize the acidity; it is always higher. Injurious effects of overliming were found to correspond to an increase in alky. Liming increased the permeability of the soil and a correlation has been found between this property and crop yield. J. S. JOFFE

The action of lime on the soil. A. GEHRING AND O. WEHRMANN. *Landw. Vers. Sta.* 103, 279-343(1925).—A detailed paper giving the results of expts. on the effect of a no. of calcareous substances, including CaO and CaCO₃ and certain com. products on several different soils. The results are discussed with special reference to the unfavorable effects of some of the treatments on soils which would be expected to respond to liming. F. M. SCHERTZ

Effect of lime on soil conditions and plant growth in field and pot experiments. D. V. DRUZHININ. *Trans. Inst. Fertilizers* (Moscow) 1925, No. 31, 1-43.—Vegetation expts. on podsol soils, limed and unlimed, were carried out; periodically detns. were made on the pH, total alky. and acidity, NO₃, NO₂, NH₄, Ca and P₂O₅ of the soil soln. and soil ext. It was found that the crop yields are closely related to the absorption capacity of the soils. Base unsatu. may be detd. by extg. with a neutral salt and titrating with phenolphthalein which according to D. gives the desired amts. of lime necessary. The field and pot expts. both checked very well in respect to the detns. mentioned. J. S. JOFFE

The degree of resistance of various limestones to acid solutions circulating in agricultural soil. E. BOTTINI. *Staz. sper. agrar. ital.* 58, 268-87(1925).—With respect to their behavior towards acid liquids limestones may be classed in 3 groups: (1) marly (d. 2.18), concretioned (2.41), arenaceous (2.31), and fossiliferous (2.26) which are most easily decomposable; (2) argillaceous (d. 2.42), of greater resistance than the former; and (3) dolomitic (d. 2.20), saccharoid (2.54), and compact (2.36) which are least easily decomposable. Examn. of 39 limestones showed that their decomposability varies inversely as their d. Exceptions are the concretioned of group (1) and dolomitic of (3), their behavior being explained by their particular compn. ALBERT R. MERZ

Annual report of the economic botanist to the government, Punjab, Lyallpur, for the year ending 30th June, 1924. J. C. LUTHRA. *Rept. Operations Dept. Agr., Punjab* 2, Part 2, 1-36(1925).—Preliminary expts. indicated that limestone nodules occurring in the fields at depths of 3.5 to 7 ft. may be a contributing factor in the cotton root-rot disease. Cotton grown on plots dug to a depth of 6 ft. and refilled with the same soil after removal of limestone nodules was far superior to that grown on untreated soil. The expts. are being continued. K. D. JACOB

The alkaline reaction of soil and its action on plants. WALTER LIEROW. *Botan. Arch.* 6, 457-65(1924); *Botan. Abstracts* 14, 768.—All fertilizers used had, with barley, a more or less pronounced influence on plant yield, but with oats only Mn fertilizing increased the yield beyond the exptl. error. H. G.

Effect of fertilizer salts on soil reaction and on the yield of various plants. BOTHO VON ROSE. *Botan. Arch.* 7, 112-33(1924); *Botan. Abstracts* 14, 769.—Physiologically acid fertilizing with (NH₄)₂SO₄ produced in barley and mustard an increase in yield, and in buckwheat and beans a decrease. Alk. fertilizing with CaCO₃ was detrimental to buckwheat. Alk. fertilizing with NaNO₃ raised not only the abs. crop production but also the proportion of straw to grain to the advantage of the grain. H. G.

Concentrated fertilizers—theory and practice. A. B. BEAUMONT. *Am. Fertilizer* 64, No. 5, 23-5(1926).—A review and discussion. W. H. ROSS

Cyanamide, its derivatives, and hexamethylenetetramine as sources of nitrogen for wheat, cabbage and white mustard in pure cultures. V. BIALOSUKNIA. *Bull. Inter. Acad. Polonaise* 1924 B, 729-37.—Ca cyanamide acts as a poison to plants in sterile water cultures on account of the liberation of free NH₃, C₂H₂ and H₂S (from impurities). Dicyanodiamide, though not poisonous, cannot serve as a source of N except in the presence of sugar (dextrose). Preliminary unsuccessful expts. using hexamethylenetetramine as a source of N are recorded. B. C. A.

How much plant nutrient is carried away during a year by our rivers? OSCAR BRAADLIE. *Meldinger Norges Landbrukshoeiskole* 4, 39-72(1924).—In samples taken weekly for 1 yr. from the Gula River were detd. the content of dry matter, loss on ignition, P₂O₅, K₂O, CaO, nitrate N, NH₃ N, org. N, total N, SO₄ and Cl. The amts. found average smaller than those from other European rivers. This is due partly to the sparseness of the population and partly to the nature of the soils and rocks in the catchment area of this river. C. A. ROBARK

The leaching of fertilizers from soils. A. W. R. JOACHIM. *Trop. Agr. (Ceylon)* 63, 277-82(1924).—Of all sol. chem. fertilizers P_2O_5 in the form of superphosphate is the least likely to be lost by leaching. Nitrates leach out very readily. A. L. M.

Tea fertilizer experiments at the experiment station, Peradeniya. T. H. HOLLAND. *Trop. Agr. (Ceylon)* 65, 3-9(1925).—Applications of potash did not increase the crop of tea in any case and apparently had no effect whatever upon the plant. Applications of N resulted in a darker green color of leaf and healthier appearance of the bushes in every case. A. L. MEHRING

Determination of ammonia nitrogen in ammoniacal fertilizers by the formalin method. WERNER SELKE. *Chem.-Ztg.* 50, 83(1926).—In the case of $(NH_4)_2SO_4$, 50 cc. of a 1% soln. were titrated with N/3 NaOH after the addn. of 5 cc. of approx. 40% CH_2O soln. (neutralized with NaOH), with a strong soln. of phenolphthalein as an indicator. The end point is a faint pink. After correcting for the original acidity of the soln. (dett. with Me orange as an indicator), the results corresponded well with those obtained by the distn. method. With NH_4 superphosphate difficulty was encountered with colloidal Al compds. formed from impurities present. With 25 cc. of a 2% soln. of the phosphate, good duplicates were obtained after allowing for the primary acidity of the soln.; but the results averaged about 0.2% lower than those from the distn. method. It is pointed out that the original acidity of the soln. was detd. with Me orange as an indicator in the case of $(NH_4)_2SO_4$, while phenolphthalein was used with NH_4 superphosphate. If the latter indicator is used with $(NH_4)_2SO_4$, low results are likewise obtained. Although these corrections may be detd. for a given sample, and when applied the results check with the distn. method, it must be concluded that in general the formalin method is inadequate for NH_4 superphosphate and likewise for $(NH_4)_2SO_4$ in case similar impurities are encountered. P. R. D.

Industrial wastes as fertilizer. I. The use of ajowan and mohua cakes as fertilizers. II. The utilization of refuse. R. D. REGE. *J. Indian Inst. Sci.* 8A, 245-65(1925).—The small amt. of thymol remaining in the press cake from ajowan (*Carum copicum*) seeds was shown to be insufficient to check the activity of soil microorganisms. Such material contains 0.862% N, 0.856% P_2O_5 , 2.02% K_2O and 12.7% ash. While of only moderate fertilizer value, it could be demonstrated that a good proportion of the N was in a form readily available to the plant, at any rate after adequate treatment. Where obtainable at low cost the cake could be used as a fertilizer. Mohua cake (from *Bassia longifolia*) contains 8.06% oil, 2.72% N, 0.12% P_2O_5 , 2.03% K_2O and 7.56% ash. An appreciable content of saponin was found to interfere with nitrification. Hence its use as a fertilizer is hardly practicable. A liquid fertilizer was prepd. by mixing powdered and sieved refuse with activated sludge. Only about 25% of its N was slowly nitrified under the most favorable conditions, the rest remaining unavailable. Better results were obtained by thoroughly stirring the refuse into the sludge, with aeration, and subsequently drying the mixt. Such a prepn. underwent fairly good nitrification in soil, but the C-N ratio exerted a marked influence. In no case was there evidence of nitrification where the proportion of refuse exceeded 10 g. per 100 cc. of sludge. It was demonstrated that a sludge effluent fixes 17.9% of the N originally in soln. upon solid waste material. A new method of sewage treatment is suggested in which the raw sewage is aerated or mech. shaken with sludge and refuse. P. R. DAWSON

The utilization of raw phosphate flour. A. N. LEBEDYANTZEV. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 34, 18-30.—Raw phosphates may be utilized on podsol and chernozem soils by grinding to a fineness of 0.02 to 0.005 mm. to increase the availability. An outline of the method of handling raw phosphate for experimental purposes is given. J. S. JOFFE

Chemical examination of the fertilizer found in the Drachenhöhle in Mixnitz, Steiermark (Austria). OTTO DAFERT AND J. HÖFINGER. *Anz. Akad. Wiss. Wien* 61, 138-9(1924).—The "phosphate earth" deposits of this cave were subjected to the solvents usually employed in agricultural analysis for dissolving phosphates to det. the condition in which the phosphoric acid occurred. The lack of const. compn. is attributed to the continual interaction of the phosphates with the soil soln., the dissolved Ca, the solid $CaCO_3$ and the Fe and Al compds. E. R. SCHIERZ

"Surophosphat" or "Dasagdünger." E. BLANCK AND F. ALTEN. *J. Landw.* 74, 38-49(1926).—A report of pot expts. with corn. F. M. SCHERTZ

The so-called "colloidal phosphorite." E. BOTTINI. *Staz. sper. agrar. ital.* 58, 209-16(1925).—This material is an almost impalpable powder, marketed lately in Italy. Its d. is 2.29 and it analyzes H_2O 4.98, PO_4 31.41, CO_2 3.00, Ca 3.57, Fe 6.38, Al 26.31, org. matter 22.47%. It is mostly composed of phosphatic granules of approx.

0.08 mm. diam. (63.06%) and shows colloidal properties only in small part (9.79%). The coarsest portions show the highest % of P_2O_5 while the colloidal portion shows only traces, being mostly org. It, as a rule, yields only traces of P_2O_5 to distd. H_2O , a satd. soln. of CO_2 or solns. of neutral org. and mineral salts. 40% NH_4 citrate, however, dissolves 1.87%. Citric acid dissolves appreciable quantities, the amt. depending on its concn. An aq. soln. contg. 40 g. citric acid, 60 g. formic acid and 100 g. NaCl per l. dissolves 7.10% as compared with 2.24, 7.04 and 10.27% by 0.5, 4.5 and 10% citric acid solns.

ALBERT R. MERZ

The use of phosphorites. G. D'IPPOLITO. *Staz. sper. agrar. ital.* 58, 243-8(1925).—A mineral superphosphate (15.17% citrate-sol. and 16.10 total P_2O_5 , 1.55 H_2O) and a phosphorite (1.80% citrate-sol. and 30.70 total P_2O_5 , 0.50 H_2O) were compared in field expts. Yields were as good from the rock, used either with or without S, as from the superphosphate.

ALBERT R. MERZ

Report of the superintendent of the Government, Guano Islands. W. R. ZEEDEBERG. *J. Dept. Agr. Union S. Africa* 11, 568-70(1925); cf. C. A. 19, 1320.—The av. compn. of guano collected during 1924 was: total P_2O_5 12.3, citric-acid-sol. P_2O_5 11.7, H_2O -sol. P_2O_5 3.1, N 9.4, K_2O 1.7 and CaO 12.7%.

K. D. JACOB

Turf-compost, a mixture for fertilizer. Z. W. LOGVINOVA. *Trans. Inst. Fertilizers (Moscow)* 1926, No. 32, 1-71.—Four types of peat, ranging in N content from 1.67 to 3.01%, were composted with raw rock phosphate to make the P sol. with lime and ashes to convert the org. N into inorg. N compd. and with liquid manure; composts were also made up of various combinations of the 3 principal composts. The results show that the org. N from peat is converted into inorg. N and that the lime necessary to bring this about is higher than that required for the satn. of the peat. Moss peat, strongly unsatd., decomposes raw phosphates, making them available. By composting moss peat with phosphates, moss peat with ashes, and then mixing the 2, previously inoculated with liquid manure, one may obtain a complete fertilizer in which the peat N may be utilized, as well as the P from the phosphate and the K and Ca from the ash. Vegetation expts. with such composts gave just as good a yield of oats as with a complete fertilizer. Meadow peat, slightly unsatd., decomposes phosphates poorly and the rate of decompn. may be correlated with the degree of unsatn.

J. S. JOFFE

Seaweed: its uses to the farmer. A. S. CARLOS. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 11, 88-9(1926).—The av. compns. of several varieties of dry English seaweed are given as: *Fucus*, N 1.5, K_2O 2.5%; *Ulva*, N 1.3% in plants from clean H_2O of the Dorset coast and 4.75% in plants from polluted waters of Belfast Lough; *Zostera* or "Hel Grass," only small amts. of N and K_2O ; *Laminaria*, stems 10-12 and fronds 5% K_2O , about 1.3% N in all parts of the plant. All of these varieties contain about 0.5% P_2O_5 on the dry basis. The use of seaweed as a fertilizer and feeding-stuff is briefly outlined.

K. D. JACOB

The significance of peat as a material for fertilizer and composts. D. N. PRIANISHNIKOV. *Trans. Inst. Fertilizers (Moscow)* 1925, No. 34, 72-5.—P. classifies the various soil regions as to their adaptability to utilize peat composts to make raw phosphates available.

J. S. JOFFE

Report of the Moscow collective fertilizer experiments. L. L. BALASHEV. *Agr. Courier (Vestnik Silsk. Khoz.)* 1925, No. 8.—This is a report of fertilizer expts. for the period 1907-1917 with a critical analysis of the value of various fertilizer ingredients.

J. S. JOFFE

Rubber fertilizer experiments at the experiment station, Peradeniya. T. H. HOLLAND. *Trop. Agr. (Ceylon)* 65, 10-6(1925).—Expts. covering a period of 10 yrs. with a variety of fertilizers are reported, with yields, effects upon the trees and amts. of rubber obtainable from the latex. The av. rubber content of the latex from trees receiving an excess of N over a period of 10 yrs. was 37.2% and from the controls 34.1%.

A. L. MEHRING

Meadows and pastures. A consideration of the causes of variation in the quality of grass. J. A. MURRAY. *Fertilizer, Feeding-Stuffs, and Farm Supplies J.* 11, 85-7 (1926).—The av. compns. of the dry matter of good and av. pasture grass, and good, av. and poor meadow hay were: albuminoids 20.6, 17.5, 16.0, 11.3, 8.8; oil 4.6, 4.0, 3.6, 2.9, 1.7; carbohydrates 46.3, 48.5, 48.2, 47.9, 44.6; crude fiber 18.4, 20.0, 23.0, 30.7, 39.1; and ash 10.1, 10.0, 9.2, 7.2, 5.8%, resp. The higher fiber content of meadow hay was largely due to the more advanced maturity of the plants rather than to variation in the botanical compn. Applications of N fertilizers promote formation of fiber by hastening the maturity of the plants and correspondingly decrease the value of the pasture. Phosphates have a pronounced beneficial effect greatly improving the digestibility of the org. matter by delaying maturity of the plants and retarding formation of

fiber. Increased development of clovers in pastures treated with phosphate fertilizer does not result in accumulation of N in sufficient quantity to cause excessively rapid maturity and consequent increase in fiber content, the optimum ratio of N to P_2O_5 never being exceeded. Attempts to correlate the chem. compn. and food value of pastures with their botanical compn. have not been generally successful. The compn. of the dry matter of 4 varieties of clover is given. K. D. JACOB

Is rain water a nitrogen fertilizer? V. ILKOV. *Rev. inst. recherches agron. Bulgarie* 3, 325-38(1925).—Analyses of snow and rain water for 3 yrs. show that on the av. there comes down yearly 1186.19 g. of N as NH_3 and 68,998 g. of N as NO_3 per dekar of soil. Rain water during the summer contains more NO_3 N than snow. J. S. JOFFE

The influence of irrigation water and manure on the composition of the corn kernel. J. E. GREAVES AND D. H. NELSON. *J. Agr. Research* 31, 183-9(1925).—Corn grown on a highly calcareous soil with and without irrigation water and manure showed an increase in the N content of the kernel due to the manure and a decrease due to irrigation as a result of the removal by the water of the readily sol. N beyond the feeding area of the plant. The ash, Ca, P and K contents of the kernel are increased with the application of irrigation water, and all the constituents are greatly increased by manure. These results support the contention that the increased ash and mineral constituents of the grain are due to an increased bacterial activity which increases the available plant food in the soil. W. H. ROSS

The nitrogen and mineral requirements of the plantain. R. V. NORRIS AND C. V. R. AYYAR. *Agr. J. India* 20, 463-7(1925).—An analysis of the plantain tree was made to est. total food requirements and to obtain information in regard to the distribution of the various constituents. Tables are included which show the weight and moisture content, % of N, total ash, distribution of K_2O , P_2O_5 , CaO , MgO and insol. mineral matter of the different parts of the tree. A table showing the % compn. of the ash from the fruit (stalk, pulp and rind) leaves, leaf sheaths, central stalk, suckers, rhizomes of suckers, roots and rhizomes of the main tree, is also given. The following is the compn. of the plantain tree: total wt. of tree 87,776, moisture 76,797, dry matter 10,979, K_2O 437, SiO_2 241.7, CaO 141, N 111.5, MgO 77.6 and P_2O_5 46.9 g. R. M. J.

Comparative investigation on the influence of different external factors especially upon the ash content of plants. RUDOLF SEIDEN. *Landw. Vers. Sta.* 104, 1-50(1925).—The external factors considered are leaf position, soil moisture, type of soil, growing period, time of day, light intensity and color, temp., artificial fertilizers and rain. In leaves of trees the ash content decreases from the base of the tree to the apex. The ash content varies with the amt. of water absorbed. It is possible to vary the ash by regulating the amt. of water and fertilizer added to the soil. In the autumn the nutrient salts migrate back to the stem. F. M. SCHERTZ

Action of zeotokol (powdered dolerite) on plant growth. E. BLANCK AND F. ALTEN *J. Landw.* 73, 213-8(1925).—This material had no significant effect upon plant growth. F. M. SCHERTZ

The effects of various methods of applying fertilizers on crop yields. D. G. COR. *Soil Science* 21, 127-41(1926); cf. *C. A.* 20, 1298.—A comprehensive study was made of the various methods of applying the more commonly used fertilizers upon the yields of corn, oats, wheat, clover and potatoes. For oats and wheat the combination fertilizer grain drill is recommended. Most economical returns were obtained with the direct contact in the seed-row method with non-caustic fertilizers. As much as 400 lb. 16% acid phosphate or 300 lb. 2-12-2 commercial fertilizer could be applied to these crops by this method with good results. Larger applications of caustic fertilizers contg. cyanamide should be made separately from the seeding, preferably 10 days in advance. Best returns from the broadcasting method were obtained where the fertilizer was subsequently thoroughly worked into the soil by disking. The side-of-hill application gave the most economical returns and the earliest maturity with corn. The side-of-row method gave the best returns with potatoes. R. BRADFIELD

Coated arsenate of lead. E. R. VAN LEEUWEN. *J. Econ. Entomol.* 18, 744-9(1925).—The following method of prepn. is given: $PbHAsO_4$ is suspended in H_2O in which a known amt. of Na oleate is dissolved. Pb acetate equiv. to the Na oleate is then added with vigorous stirring. The product consists of Pb oleate in minute globules intimately mixed with $PbHAsO_4$. When dried a water-repelling powder is obtained in which the particles of arsenate are coated with Pb oleate. The min. quantity of Pb oleate necessary to cover was detd. as follows: A weighed amt. of $PbHAsO_4$ powder was mixed in C_2H_5 contg. a known amt. of Pb oleate in soln. The C_2H_5 was evapd and a small quantity of the dried powder shaken with H_2O . The coated arsenate is

not wetted and floats whereas the uncoated arsenate sinks. In this way it can be ascertained whether coating is complete. More than 0.25% of Pb oleate is required for complete coating. Expts. indicate that the coated PbHAsO_4 kills a higher % of the beetles than the uncoated, that it spreads evenly on foliage and adheres better than the uncoated compd. It is practically unaffected by rains. C. H. R.

Spreaders for spray materials and the relation of surface tension of solutions to their spreading qualities. R. H. ROBINSON. *J. Agr. Research* 31, 71-81 (1925).—No definite proportional relationship could be established between the surface tension values of spreader solns. and the observed spreading properties of the different substances. Of the materials tried, water-sol. protein substances gave the best spreading at the lowest concn. for the greatest no. of surfaces tested. Skim milk, neutralized with $\text{Ca}(\text{OH})_2$, and certain other milk products appear to be the best materials for practical purposes. The concn. of a spreader soln. that will give the best results depends upon a no. of variable factors, such as the type and age of the surface to be sprayed, the force used and climatic conditions. The amt. of Pb arsenate that adheres to the leaf surface is approx. the same when a spreader is added as when one is not. W. H. ROSS

Preliminary report on colloidal clays as emulsifiers for mineral oils used in spraying citrus groves. W. W. YOTHERS AND J. R. WINSTON. *J. Agr. Research* 31, 59-65 (1925).—Kaolin, fuller's earth and other colloidal clays may be used in lieu of soap in making emulsions of mineral lubricating oils for spraying citrus trees. These emulsions are about as effective against insect pests as the soap emulsions, and are no more likely to cause spray burn. They mix with any water or desired spray combination without special treatment, are easily made, keep indefinitely and cost much less than soap emulsion. The principal objection to these emulsions is that they are a semipaste rather than a fluid. Satisfactory lime-sulfur oil emulsions may also be made with kaolin or fuller's earth, but the use of these emulsions in spraying young orange trees resulted in greater injury than good grove practice would allow. W. H. ROSS

Contributions to the biochemistry of the action of mercury compounds upon the spores of wheat smut. J. BODNÁR AND ALEXANDER TERÉNYI. *Chem.-Ztg.* 50, 109-10 (1926); cf. C. A. 20, 793.—Detns. were made of the Hg adsorbed by spores from solns. of HgCl_2 , HgBr_2 , $\text{Hg}(\text{OAc})_2$ and $\text{Hg}(\text{CN})_2$ in 15 min. The greatest amt. was adsorbed from $\text{Hg}(\text{OAc})_2$, followed by HgCl_2 and HgBr_2 , while none was adsorbed from $\text{Hg}(\text{CN})_2$. In germination expts. on $\text{Ca}(\text{NO}_3)_2$ soln. spores thus treated did not germinate within 20 days in the case of all except $\text{Hg}(\text{CN})_2$ where normal germination took place. In similar expts., with soils as substrates, spores treated with HgCl_2 and HgBr_2 showed no germination, while in the case of $\text{Hg}(\text{OAc})_2$ it was only delayed. The killing action of the Hg halides and the inhibiting effect of the acetate are explained as follows: The former are weakly dissociated and are adsorbed as the entire salts which, as lipid compds., penetrate the cell walls and combine with the protein of the interior; the latter, however, is well dissociated, only the Hg is adsorbed and remains on the surface of the cell, whence it can be gradually removed by the soil moisture. $\text{Hg}(\text{CN})_2$ is without effect since it is not dissociated and likewise does not form lipid compds. Apparently a dissociated Hg compd. behaves as does Cu, merely inhibiting germination. The min. concn. required to inhibit germination in $\text{Ca}(\text{NO}_3)_2$ soln. is 0.0011% in the case of the most effective salt tested, HgBr_2 , and is more than is required for Cu, 0.00075%. P. R. DAWSON

Annual report of the entomologist to government Punjab, Lyallpur, for the year ending 30th June, 1924. M. A. HUSAIN. *Rept. Operations Dept. Agr., Punjab*, 2, Part 2, 55-90 (1925); cf. C. A. 19, 3141.—HCN was effective against adult bruchids and *Trogoderma Khapra* grubs in stored gram but bruchid grubs inside the grain were not killed. CS_2 at the rate of 1 ounce per 15 cu. ft. was effective against all stages of various insects infesting gram in storage. K. D. JACOBS

Possibilities of an ovicide as an auxiliary in codling moth control. L. CHILDS. *J. Econ. Entomol.* 18, 665-74 (1925).—A dil. petroleum oil emulsion contg. 3% oil gave promising results. C. H. RICHARDSON

Laboratory experiments with arsenicals in the control of the codling moth. E. J. NEWCOMER. *J. Econ. Entomol.* 18, 679-80 (1925).—This is a summary of methods and results obtained from lab. work. Pb arsenate, Ca arsenate, Zn arsenite and Paris green were used. C. H. RICHARDSON

Notes on oils. A. L. MELANDER. *J. Econ. Entomol.* 18, 681-6 (1925).—The addn. of Ca caseinate spreaders to oil sprays reduced their effectiveness. C. H. R.

Relation of soil conditions and orchard management to the rosette of pecan trees. J. J. SKINNER AND J. B. DEMAREE. U. S. Dept. Agr., *Bull.* 1378, 1-16 (1926).—A chem. examn. of the soils of 2 pecan orchards subjected to different cultural treatments

showed that the accumulation of org. matter and N in the soils, whether acquired by the growing and plowing under of cover crops or by the addition of manure, composts, etc., stimulates increased growth and yield and results in complete disappearance of all rosette symptoms on the trees. Chem. fertilizers had no influence in decreasing or increasing rosette and no correlation of soil acidity with good or poor pecan orchard was noted.

W. H. ROSS

Spraying for weed eradication. WINIFRED E. BRENCHELEY. *J. Bath and West and Southern Counties Society* 19, 1-20(1924-5).—A summary and discussion of the exptl. data upon the efficacy and economy of various sprays, and combination fertilizer and spray materials, utilized for weed eradication.

P. R. DAWSON

The practicability of quantitative toxicological investigations on mandibulate insects. F. L. CAMPBELL. *J. Agr. Research* 32, 359-66(1926).—The ability of certain mandibulate insects to imbibe completely drops of poison solns. has been utilized as a basis for the development of methods for the quant. toxicological examn. of sol. arsenical stomach-poison insecticides. By the use of these methods it has been found that tervalent As is more toxic than quinquivalent As, that different species vary in susceptibility to As poisoning, and that the min. lethal dose of As for the 2 species studied is about 0.02 mg. of As per g. of insect.

W. H. ROSS

The effectiveness of certain paraffin derivatives in attracting flies. WM. C. COOK. *J. Agr. Research* 32, 347-58(1926).—The relative attractiveness of paraffin alcs. and esters to flies is related to the b. ps. of the compds. As the b. p. becomes higher the attractiveness decreases, and for each of the compds. studied there is a definite optimum concn. which becomes smaller as the b. p. rises. The addn. of a CH_3 group to the acid radical reduces the attractiveness much more than the addn. of a similar group to the alc. radical. Of a given set of isomeric compds., that one is generally most attractive which has the lowest acid radical. Iso or branched chain compds. are relatively more attractive than their normal isomers and the difference in attractiveness increases with the b. p.

W. H. ROSS

A summary of the answers received to questions on the mechanics of spraying. E. R. DEONG. *J. Econ. Entomol.* 18, 722-6(1925).—An analysis of 82 answers to a questionnaire on spray mechanics is given. It includes the trend of opinion on spraying pressures, rate of discharge from nozzles, size of aperture of spray nozzles and related subjects.

C. H. RICHARDSON

The value of sprays for black scale control in California. R. S. WOGLUM AND J. R. LAFOLLETTE. *J. Econ. Entomol.* 18, 726-9(1925).—Three petroleum oil sprays (2 of them mixed with lime-S soln.) have shown results superior to fumigation with HCN. Effects of oil sprays on citrus trees and fruit are discussed.

C. H. R.

Some effects of *Tribolium* on flour. N. M. PAYNE. *J. Econ. Entomol.* 18, 737-44(1925).—*T. confusum* affects the elasticity and viscosity of flour. The adults give off a water-sol. secretion which may be the cause of these effects.

C. H. R.

Combating insect and animal pests with bait-containing arsenic. KREIG. *Centr. Bakt. Parasitenk.* 65, 59-69(1925).—The following formulas are suggested: lead arsenate 60 g., molasses 3 l. and water 100 l., or molasses 10 kg., sodium arsenite 300 g. and water 100 l.

JOHN T. MYERS

House fumigation with calcium cyanide. R. C. SMITH. *J. Econ. Entomol.* 19, 65-77(1926).—Ca cyanide is a promising substitute for NaCN in house fumigation. The relation of temp. and humidity to the evolution of HCN from this compd. is discussed; also the effects of HCN on metals, wall paper colors, costs of fumigating, etc.

C. H. RICHARDSON

Studies of some adsorbed insecticides. C. O. EDDY. *J. Econ. Entomol.* 19, 77-86(1926).— Na_2AsO_3 , Na_2AsO_4 , K_2AsO_3 and K_2AsO_4 were adsorbed on kaolin, diatomaceous earth, fuller's earth, talc and tripoli. Expt. I: A quantity of the As salt was dissolved in enough H_2O to wet thoroughly the carrier and the material was dried and reduced to a fine dust. The quantity of As adsorbed was 0.17-0.42 g. per 100 g. dust, av. 0.24 g. The amt. adsorbed depends chiefly on the kind of carrier and to a lesser degree on the As salt used. The effectiveness of the carriers as absorbents was: kaolin > diatomaceous earth > fuller's earth > talc < tripoli. Na_2AsO_4 is probably adsorbed in greatest quantity and K_2AsO_4 in least. As the amt. of As mixed in the carrier is increased the adsorption of As becomes greater. When NaOH is added in amts. sufficient to neutralize the acidity of the As salt plus 1%, the adsorption of As is decreased; and the relative position of the carriers as absorbents is changed. Expt. II: A large excess of As salt was used in this expt. (200 cc. per 25 g. carrier). The amt. of As removed from the soln. by the carriers varied chiefly with the carrier and less so with the As salt. The order of removal was: kaolin > diatomaceous earth > tripoli =

fuller's earth = talc. Talc removed more As than fuller's earth from solns. of Na_2AsO_4 and K_2AsO_4 , but the same amt. from solns. of Na_2AsO_3 and K_2AsO_3 . The carriers removed the largest amt. of As from Na_2AsO_4 solns., the least from Na_2AsO_3 solns. The amt. of As removed was greater in this expt. than in Expt. I. The variable colloidal nature of the carriers was a disturbing factor. Expts. with these dusts on the Colorado potato beetle (*Leptinotarsa decemlineata*) and the Mexican bean beetle (*Epilachna corrupta*) indicate possibilities for their use against chewing insects without danger to plants.

CHAS. H. RICHARDSON

Determination of nicotine (MACH, SINDLINGER) 7. Bacterial S oxidation in pond soils and its practical value (FISCHER) 11C. A green bacterium [in soils] (SACK) 11C. Use of the chlorine gas process in the paper industry [insecticides from waste liquor] (CONSIGLIO) 23.

ANDRÉ, G.: *Chimie agricole, chimie végétale*. Ed. 3 revised. Paris: J. B. Baillière. V. I, 442 pp., V. II, 460 pp. Reviewed in *Tech. Book Review Index* 8, No. 2, 141(1924).

EMERSON, PAUL: *Soil Characteristics: A Field and Laboratory Guide*. London: McGraw-Hill Pub. Co., Ltd. 222 pp. 12s. 6d. Reviewed in *Bull. Imp. Inst.* 23, 527(1925).

Insecticides. W. K. SCHWEITZER. U. S. 1,574,118, Feb. 23. An aq. slurry contg. dimanganooarsenate is digested with compds. such as MnCO_3 to form less sol. arsenates.

Insecticide. C. N. HAND. U. S. 1,573,490, Feb. 16. A thiourea, *e. g.*, sym. diphenylthiourea, and S are used on cotton or potato plants, etc.

Insecticide and fungicide for injection into trunks of trees. C. M. ROELOFSZ. Brit. 237,256, July 16, 1924. A mixt. of lime, S and Pb arsenate is slaked with a small quantity of H_2O , more H_2O is added after the slaking is completed, and the soln. is strained.

Fungicides. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 237,388, May 23, 1924. Seed grain is treated to destroy spores of fungoid diseases by use of a cyanide or hydroferrocyanide together with Hg compds. such as the Na compd. of hydroxymercuri-p-cresol. Cf. C. A. 19, 556.

Colloidal compounds of arsenic. A. CHWALA. U. S. 1,573,375, Feb. 16. Pb arsenate or other As compd. is mech. dispersed in the presence of Na protalbate or other protective colloids and of Ca plumbate or other salts of inorg. acids derived from higher oxides of a metal combining with O in several proportions. The products thus prepd. are suitable for use on plants to combat parasites.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The significance of "buffer substances" in the fermentation industries. P. BERMANN. *Woch. Brau.* 42, 267-8, 273-5(1925).—The Wolff indicator method was tried and found accurate in detg. the p_H of molasses and malt worts. A graphical method for detg. p_H and titratable acidity was developed. The titration curves obtained from molasses fermentations are an indication of significant changes in the wort, and aid in detg. whether or not a normal fermentation has been obtained. Wildier's "bios" may be defined from a physiol.-chem. point of view as a "buffer substance regulating the fermentation of a nutrient soln. by yeast." The buffer substance of a malt may serve as a criterion of its value as a fermenting material.

C. N. FREY

Determination of the final attenuation in malt analysis. L. HEINTZ. *Woch. Brau.* 42, 127(1925).—The mash is prepd. in the usual way and heated to 70°. It is then allowed to stand 55 min. after which the bath is heated to 97-8°. After cooling the mash is filtered, placed in a cask, the cork having an orifice for the escape of gas, and the wort is seeded with yeast. The spent wort is analyzed after growth has ceased.

C. N. FREY

The changes in the degree of dispersion of proteins of barley during malting, mashing and during fermentation. W. WINDISCH, O. KOLBACH AND E. WENTZELL. *Woch. Brau.* 42, 287-8, 295-7, 303-6, 313-7, 323-4, 333-5(1925).—By means of fractional ultrafiltration (Bechhold, C. A. 1, 2762) during mashing, malting and fermenting

it was shown that during malting finely dispersed protein material increased more rapidly than the coarsely dispersed. During the drying of malt the coarse particles and non-ultrafilterable proteins as well as the finely dispersed ultrafilterable proteins are decreased. Cooking with hops increases the amt. of sol. protein at the expense of medium-sized particles of proteins, but the cooking stabilizes the proteins. During storage if the wort has the same p_H as the beer, great changes occur in the dispersion of the protein and a large part of the albumin is coagulated. This makes the procedure of detg. assimilable N during fermentation difficult because the yeast takes up the sol. nitrogenous compds. By cooking the fermented wort changes in the non-filterable soln. take place, most of the coagulation occurring at 70°. If part of the particles of nitrogenous material increases in size and the amt. of ultrafilterable material also increases, there is a consequent decrease of size of particles. Cooking of non-fermented worts produces an increase of ultrafilterable nitrogenous compds. The optimum p_H of protein enzymes of malt is 4.9 and the optimum temp. 46°. The enzymes are destroyed in alk. solns. The liquefying peptase has an optimum p_H of 3.7-4.3 on gelatin and p_H of 6.2 on peptone. The proteins of malt are leucosin, proteoses, edestin, hordein and undetd. nitrogenous substances. Curves are appended showing N content of malt ext., green malt and fermented wort after filtering through membranes. The amt. of coagulated N is also given. The size of the particles passing through the membranes ranged from 15 to 500 μ in diam.

C. N. FREY

Development of free acidity during the fermentation of beers. M. H. VAN LAER. *Petit J. Brass* 33, 674(1925).—The principal factors detg. the increase of free acidity in wort during fermentation are its compn. and the yeast. The term "buffer index" is proposed for the value obtained by the formula $10/(P_1 - P_2)E$, where P_1 is the p_H of the wort and P_2 the p_H detd. after addn. of 1 cc. of 0.1 N acid to 25 cc. of the wort, and E is the ext. in degrees Balling. The buffers in wort prevent an increase of H-ion concn. during fermentation. A wort too rich in buffers would give a beer with insufficient free acidity and in consequence diminished stability. A diminution of buffer index should correspond, therefore, to an increase of free acidity during fermentation. The titration curve of beers indicates that the buffers consist of a mixt. of phosphates and org. acids (lactic and acetic acids and amino acids). Comparative brews with malt and with malt together with 40% of rootlets gave buffer indices of 1.29 and 2.40, resp., indicating that a high proportion of highly degraded N compds. has considerable effect on the buffer index, giving beers with too low free acidity. Forcing conditions during malting would lead to malts rich in buffers and result in beers with an insufficient free acidity. The effect of the yeast during fermentation is to produce less acidity in a medium already acidified before fermentation and more in an alk. wort. With beers of insufficient acidity, less acid will be required to produce the same p_H when added to the wort after primary fermentation than when added before.

B. C. A.

Large fermentation vessels. F. EMSLANDER. *Woch. Brau.* 42, 146-8(1925).—The size of fermenters and the relation of size to fermenting activity are considered.enameled iron is excellent for small fermenters, but cannot be used in constructing large ones. Al is not a satisfactory material for fermenter construction.

C. N. FREY

Production of alcohol from rice straw. NOBORU TAKETOMI. *J. Soc. Chem. Ind. Japan* 29, 43-7(1926).—Rice straw (12.89% ash, 17.49% pentosan, 0.76% crude fats, 35.02% crude fiber and 2.88% crude proteinis of 87.45% dry matter) was heated with 1% H_2SO_4 at about 134° for 30 min. in an autoclave. The liquid thus obtained was neutralized with $CaCO_3$, concd. and fermented with the distillery yeast, Race XII. The yield of sugar produced is about 15% of the dry matter used and that of alc. about 5.4%.

K. K.

Bulgarian wines. D. WESSOW. *Rev. inst. recherches agron. Bulgarie* 3, 13-24 (1924).—Analyses are given and methods of adulteration discussed.

E. H.

In what chemical form does silicic acid exist in water? (WINDISCH) 14. Volumetric determination of alcohol (CHABOT) 7.

Denatured alcohol. H. C. FULLER. U. S. 1,573,697, Feb. 16. EtOH is denatured by the addn. of a halogen-contg. ester of glycerol, e. g., glyceryl monochlorohydrin and monochloroacetylmonoglyceride. U. S. 1,573,698 specifies a chloroacetic ester of ethylene glycol or other halogen fatty acid ester of a polyhydric alc. as the denaturing agent.

Apparatus for mixing alcohol with denaturing substances. F. E. LICHTENTHAELER. U. S. 1,575,433, March 2.

Acetone and butyl alcohol by fermentation. G. W. FRENCH. *Brit.* 237,228, July 17, 1924. See U. S. 1,537,597 (*C. A.* 20, 476).

Diastatic malt sirup or wort. H. E. DUBIN. U. S. 1,573,611, Feb. 16. A diastatic ext. or wort is subjected to a limited or "mild" treatment with a solid adsorbent decolorizing agent such as charcoal to effect decolorization without any substantial reduction of enzyme activity.

Ammonia from vinasses. G. P. GUIGNARD. U. S. 1,576,427, March 9. A vinasse contg. H_2O is heated to 450–550° *in vacuo* (the vacuum and temp. being maintained during the whole treatment) to produce NH_3 and other by-products.

Kiln for drying hops, etc. WOLMER (R. C. PALMER) VISCOUNT. *Brit.* 237,418, July 4, 1924.

Apparatus for separating grains from wort. W. H. CAMPBELL. *Brit.* 237,321, Mar. 26, 1924.

Apparatus for steaming grain. H. R. SPAULDING. U. S. 1,574,210, Feb. 23.

Yeast. C. HOFFMAN, N. M. CREGOR and H. D. GRIGSBY. U. S. 1,575,761, March 9. A mash is prepd. by gelatinizing starch-contg. materials including cereal germs and polishings, the mass is saccharified with malt and digested with papain, the liquid filtered off and yeast is propagated in it with aeration.

Yeast preparation. R. WILLSTÄTTER and H. SOBOTKA. U. S. 1,574,776, March 2. A prepn. rich in vitamins and enzymes and which is adapted for use in baking or brewing is formed by mixing yeast with at least $1/3$ its wt. of a disaccharide other than sucrose, *e. g.*, with maltose, to initiate plasmolysis of the yeast, and then heating the mixt. to produce liquefaction without fermentation. Cf. *C. A.* 19, 2094.

Preserving yeast. L. LINDEMANN. U. S. 1,574,494, Feb. 23. Fresh yeast is distributed and washed in H_2O having a temp. of about 33–43° until tests show complete or nearly complete removal of glycogen. This treatment is carried out with the purpose of increasing the durability of the yeast.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Notes on the preparation and use of the ethyl esters from "the Chaulmoogra oils." B. E. READ. *China Med. J.* 39, 612–8(1925).—An account of the technic followed in the P. U. M. C. Lab., Peking, is accompanied with details as to ester yields on fractionation. Expt. indicates that rotatory power is the best index of purity. The product is guaranteed to be free from free fatty acid, which is the source of irritating therapeutic effects.

Bibliography of chaulmoogra oil. B. E. READ. *China Med. J.* 39, 623–31(1925). W. H. A.

Detection of ethyl phthalate in essential oils. H. THOMS. *Apoth.-Ztg.* 40, 196 (1925).—An adulteration of 10% of Et phthalate may be detected in certain essential oils as follows. The oil is evapd. to dryness on a water bath with EtOH and NaOH soln. If a resinous residue is obtained, this is extd. with water and the aq. ext. evapd. to dryness. The residue is treated with cold H_2SO_4 and resorcinol and heated at 80–85°. Some of this mixt. is then added to NH_3 soln. Freedom from Et phthalate is shown by the absence of any greenish yellow fluorescence after 15 min. Certain phenols such as eugenol interfere with the test since they also yield fluorescent condensation products with resorcinol.

Unpleasant taste of radix primulae. L. KOFLER and M. BRAUNE. *Arch. Pharm.* 263, 424–30(1925).—The root of *Primula veris* as also that of *Primula elatior* contains a substance or mixt. of substances, entirely distinct and separable from saponin, and responsible for its unpleasant taste. The substance dissolves readily in neutral, alk. and acid H_2O . The name "Primelkratzstoff" is tentatively suggested. W. O. E.

Choice of indicators for alkaloidal titrations. H. WALES. *Ind. Eng. Chem.* 18, 390–2(1926).—The procedure followed in the present investigation was essentially that of Rasmussen and Schou (cf. *C. A.* 19, 702, 2388). The indicators (methyl red = a, propyl red = b, bromocresol purple = c, bromophenol blue = d) employed and the

(a) 0.80; cocaine (a) 0.20; cocaine (b) 1.00; cocaine (c) 0.80; cocaine (d) 0.80; acetylmorphine (a) 4.89; emetine (a) 4.90; ethylhydrocupreine (c) 6.33; ethylmorphine (a) 4.99; homatropine (a, b, c) 5.74; hydrastine (no end point with a or d) 4.45; hyoscyne (d) 4.83; hyoscyamine (a, b, c) 5.83; morphine (a) 4.68; narceine salt completely dis-

sociated; narcotine (d) 4.43; nicotine (a) 5.26; papaverine, indistinct cannot be titrated; physostigmine (a) 4.85; pilocarpine (d) 4.31; quinine (c) 6.12; quinidine (c) 6.10; sparteine salt completely dissoc.; strychnine (a) 4.81; thebaine (a) 5.08; yohimbine (a) 4.72. The paper concludes with a bibliography. W. O. E.

Geranium rose oil. ANON. *Perfumery Essent. Oil Record* 17, 46(1926).—A sample grown in S. India from plants imported from Grasse had a rich yellow color, was quite clear and free from deposit, and a little more mobile than the usual geranium oils. The odor character is in keeping with that of the product from the distn. of geranium over roses, reminding one of the naturalness obtained by the use of phenethyl butyrate when toning up rose compns. As a sweetener and improver this sample is shown to be applicable to all kinds of perfumery since it compares favorably with the com. oil distd. over roses. W. O. E.

Travancore wild orange blossom oil. ANON. *Perfumery Essent. Oil Record* 17, 46-7(1926).—The sample was a rich yellow, mobile oil which at once suggests in odor character the Portugal oil (neroli) obtained from *Citrus aurantium*, but which does not occur in commerce; the so-called neroli is usually a mixt. of the several oils of the orange type. It is wanting in the depth and character natural to the Bigarade blossom oil; it is also a little inferior in lasting power to a sample of the best Portugal oil obtainable. W. O. E.

Determination of moisture in cloves. PERCY MAY. *Perfumery Essent. Oil Record* 17, 65(1926).—Introduce 50 g. of the sample together with 100 cc. of petroleum white spirit (d. 0.8135 and b. about 165-95°) into a short-necked flask, connect with a reflux by attaching to the lower end of condenser a graduated eprouvet-shaped receiver having a side connection with the flask. As the spirit boils, and condenses together with entrained H₂O vapor, the latter being heavier sinks into the graduated point while the overflowing spirit returns to the flask. After boiling $\frac{3}{4}$ of an hr. the vol. of the H₂O is read off. Zanzibar and Penang cloves usually carry about 13% of moisture. W. O. E.

Odor intensity and odor quality. JOHN MISSENDEN. *Perfumery Essent. Oil Record* 17, 62-4(1926).—The whole question of odor depends on 3 factors: intensity, quality and olfactory sense. Before a substance can be detected by the organs of smell, it must actually come into contact with the nasal membranes, the degree to which it does so det. the intensity of the odor. Having reached the nasal membranes, the substance will then set up a chem. action with the lipinous fluid contained therein, and this chem. action det. the quality of the odor. It, therefore, becomes obvious that if the chem. action or force of mol. interchange is great, the quantity of substance small and widely diffused into the air, the rate of chem. action will be slow and the effect upon the nerve-centers will be correspondingly slight. On the other hand, if the quantity of substance is great, but the force of mol. change small, the odor of a substance might be quite characteristic though not powerful. Lastly, if both force of mol. interchange and quantity of substance are great, the effect is likely to be protrating, as may be demonstrated by the 2 examples NH₃ and PhNO₂. The whole basis of the "lipin theory" is that anything which causes violent or rapid reaction with lipin is pungent or unpleasant, and anything which causes no reaction is odorless, with a graduated scale between these 2 extremes. A convenient classification of odors seems possible, provided that the rate of chem. action upon lipin be studied, and also provided that a standard lipin can be obtained synthetically. W. O. E.

Crystalline insulin. J. J. ABEL. *Proc. Nat. Acad. Sci.* 12, 132-6(1926).—Insulin was obtained in the form of colorless *rhombohedral* crystals. Dissolve 1 g. of fraction IV (C. A. 19, 2964) in a slight excess of N/6 AcOH and dil. to about 60 cc. Add a 6% soln. of brucine in N/6 AcOH. Sep. the supernatant fluid by centrifugalization and ppt. the insulin by the addn. of N/6 pyridine. It may be recrystd. by dissolving in M/15 Na₂HPO₄ and adding N/6 AcOH with vigorous shaking until a slight turbidity persists. On standing overnight, the crystals sep., m. 233° with slight browning at 215°. The crystals contain *labile* S and give the biuret, Millon, Pauly and ninhydrin reactions. They lose their hypoglycemic activity on boiling for 15 min. with 0.1 N Na₂CO₃. Quantities as small as 0.008 mg. per kg. lowered the blood sugar of rabbits to the convulsion level within 5 hrs. ARTHUR GROLLMAN

Biologic assay of the vaso-hypertensive and oxytocic activities of pituitary extracts. C. HEYMANS. *Arch. internat. pharmacodynamie* 30, 275-90(1925).—By employing a new technic for assaying the vascular activity of pituitary exts., involving the perfusion of the isolated head of a rabbit, H. found great variations in com. prepn., all of these being too weak. Similar results were found in regard to the oxytocic activity of com. prepn. tested. Voegtlin's standard powder is recommended as the most suitable for the international standardization of this biol. product. W. A. P.

Fernand Ranwez (1866-1925). "G. M." *J. pharm. chim.* [8] 2, 160-1(1925).—An obituary. S. WALDBOTT

Action of salts of mercury on the veronal series. Analytical applications. P. FLURY. *J. pharm. chim.* [8] 2, 465-76(1925); cf. P. Lami, *C. A.* 10, 2613.—The 5 medicinal derivs. of barbituric acid (MH_2): (1) MEt , (2) $M(PhEt)$, (3) $M(BuEt)$, (4) $M(CMe_2C_4H_5)$, (5) $M(C_4H_5)$, present definite reactions towards the following 3 Hg reagents: *A*: an acid $HgSO_4$ soln. (50 g. red or yellow HgO in 200 cc. H_2SO_4 , d. 1.84 and 1 l. H_2O); *B*, a more neutral soln. (70 g. crystd. $HgSO_4$ in 45 cc. H_2SO_4 and H_2O to make 1 l.); *C*, a satd. aq. soln. of $HgCl_2$. Cold aq. solns. of 1 to 5 produce with *A* or *B* white gelatinous ppts. insol. in H_2O , sol. in dil. (about *N*) HCl . With *B*, the soly. limits vary from 1:10000 to 1:80000. *C* does not ppt. with 1, 2, 3, but ppts. hot, concd. solns. of 5 (limit 1:125000) and cold concd. solns. of 4 (limit 16600); insol. in dil. HCl . With *D*, 1, 2, 3 the general compn. of the ppts. obtained with *A* and *B* (*D*) = $X D$. *y* HgO is, rather const.; with 1 and *A*, the ratio $x:y = 3:2$; with *B*, 3:2.5; with 2 and *A*, 3:2.5, with 3 and *A* or *B* 3:2.25, varying somewhat with the concn. of 3. The 4 and 5 derivs. form adsorption compds. with *A* and *B*, higher in HgO ; in 4 $x:y = 3:2.5$ and 3:3; 5 also contains $HgSO_4$, and the compn. after washing with H_2O is 3 $M(C_4H_5)_2.5HgO$. 0.55 $HgSO_4.5H_2O$. With *C*, if used in large excess (15 vols.), pptn. of 4 is quant.: 3($M(Me_2C, C_4H_5)2H_2O$) 3.5 HgO . $HgCl_2$; pptn. of 5, yielding 3($M(C_4H_5)_2.H_2O$) 4.5 HgO . 1.5 $HgCl_2$, is not quant. at any excess of *C*. All these ppts. are sol. in dil. KCN , permitting an indirect detn. of Hg by the Denigès $KCN-AgNO_3$ method, given in detail. Detn. is exact for 2 only; for 1 and 3, corrections for soly. must be made. With 4 and 5, results are 20-30% too low in Hg, because in the adsorption compds. the Hg is no longer in the ionic state. S. WALDBOTT

Determination of santonin in flores cinæ. R. FÖDER AND W. SCHNEITER. *Schweiz. Apoth. Ztg.* 63, 405-9, 421-5, 433-9, 453-8(1925).—After a crit. review of the methods of Katz (1899), Heyl and Tunmann (*C. A.* 7, 2090), Goerlich (*C. A.* 5, 1163), Fromme (*C. A.* 6, 3311), Van den Berg (*C. A.* 17, 3226), Favrel (*C. A.* 18, 149), Schaap (*C. A.* 18, 1546) etc., the following method is proposed for official adoption: Shake 10 g. of finely powdered drug with 100 g. C_6H_6 for 30 min., filter off 81 g. and remove C_6H_6 completely by distn. and exposing the residue to a current of air. Boil the residue for 15 min. under reflux with 40 cc. of 15% $HtOH$ by wt., filter hot through cotton, wash with 2×5 cc. of hot 15% alc., cool, add 0.1 g. white bole, again boil for 15 min. under reflux, filter and wash with 2 or 3×5 cc. hot 15% alc. and set aside for 24 hrs. in the dark. Weigh the soln., filter, rinse with a little cold H_2O , dry for 1 hr. at 100° , cool and weigh after 30 min. For each 10 g. of soln. add 0.006 g. santonin (*A*) in calcul. The wt. found refers to 8 g. of drug, which should contain at least 1% of *A*, m. 170° when pure; found m. $163-5^\circ$. When the content in *A* is low (0 to 0.8%), add 1.5-2% of pure *A* so as to obtain well crystd. *A* for detn. S. WALDBOTT

Cod-liver oil, its origin, preparation and active principles, notably its vitamin content. J. LANG. *Schweiz. Apoth. Ztg.* 63, 473-5, 517-9, 535-7, 546-50(1925).—A lecture. S. WALDBOTT

A pharmacodynamic study of the anthelmintic properties of two oils of chenopodium. A. R. BLISS, JR. *J. Am. Pharm. Assoc.* 14, 93-8(1925).—See *C. A.* 19, 1472. I. E. WARREN

Endocrine products. P. S. PITTINGER. *J. Am. Pharm. Assoc.* 14, 99-107(1925).—A review for pharmacists. I. E. WARREN

A pharmaceutical study of acetylsalicylic acid. HARRIET V. SNIDOW AND H. A. LANGENHAN. *J. Am. Pharm. Assoc.* 14, 125-8, 694-703(1925).—History of the discovery, incompatibilities and color reactions. Preliminary expts. with numerous mixts. to det. incompatibilities were made but the work is not completed. I. E. WARREN

The paramerial method for the biologic assay of the digitalis series. ALBERT SCHNEIDER. *J. Am. Pharm. Assoc.* 14, 128-9(1925).—The technic of the method is described. It is essentially the same as that for detg. the phenol coeff. of disinfectants by the paramerial method (*C. A.* 19, 1473). *P. caudatum* and other species of *P.* appear to be quite resistant to the digitalis series. The results obtained by the paramerial method with preps. of digitalis, strophanthus, apocynum and squill, do not correspond with the results obtained by the official 1-hr. frog method. The comparative results are lower than those given in the U. S. P. The method is in the experimental stage, but the results appear promising. I. E. WARREN

The state of silver in protargol (argenti proteinatum) and collargol (colloid silver argenteum cr   ). I. M. KOLTHOFF. *J. Am. Pharm. Assoc.* 14, 183-9(1925).—Com. preps. of protargol and collargol were studied. In detg. *N* in protargol by the Kjeldahl

method a catalyzer must be used. The soln. becomes colorless in 2 hrs. without a catalyzer but the N is 1% low. The N content is 13.8%. Protargol contains about 0.85% AgCl. The collargol specimen contained 67% of Ag of which 4.8% was in the halide state. The Ag-ion concn. was detd. by the potentiometer with a Ag electrode. The value for protargol is about 10 times as great as in collargol. The preps. were titrated with a standardized KI soln., the potentiometric method being used. By this it is possible to det. the total Ag and the Ag present as AgCl. The first rise in potential occurs after the transformation of the Ag proteinate into AgI and the second after the transformation of the AgCl into AgI. Protargol soln. is a good buffer for Ag ions between p_{Ag} 2.8 and 4.0. Collargol contains nearly all of the Ag in the metallic state but only a small part is in an ionogenic state. It contains about 5% of its Ag as AgCl.

Belladonna plaster. F. B. KILMER AND P. L. HUNT. *J. Am. Pharm. Assoc.* **14**, 241-9(1925).—Historical essay. K. and H. conclude that the U. S. P. IX alkaloidal standards for belladonna plaster are satisfactory, and in conformity with the other pharmacopeias of the world. The U. S. P. IX method of assay with slight modifications gives satisfactory results. The principal recommended change is the use of methyl red instead of cochineal as an indicator.

L. E. WARREN

A simple and rapid electrometric determination of alkaloids without the use of hydrogen electrode. STEPHEN POPOFF AND M. J. MCHENRY. *J. Am. Pharm. Assoc.* **14**, 473-6(1925).—A plain Pt wire is used in place of the H electrode. The app. consists of a student potentiometer, lamp and scale galvanometer, Weston standard cell, 2 dry cells and a 3-dial resistance box set up in the usual way. The satd. type of HgCl and a plain Pt wire serve as the electrodes. The latter is cleaned after titration by dipping it into a cleaning mixt. (dichromate) for a few min. and washing it thoroughly. The titration flask is a 300-cc. tall beaker ground to fit tightly against a glass plate. In the plate are 6 openings, one for a stirrer (electrically driven), the second for a HgCl capillary tubing, the third for a T tube into which the Pt wire is fastened and which is used for passing CO₂-free air, the 4th and 5th openings are for 2 burets, and the 6th opening is for washing down the sides of the beaker. Dissolve the alkaloid or alkaloidal salt in either EtOH or a mixt. of EtOH and H₂O, and expel CO₂ from the beaker. To free alkaloids add excess 0.1 N HCl and then KOH until 2 breaks are obtained. Altogether there are 3 breaks, the 1st representing the conversion of alkaloid to the hydrochloride, the 2nd representing the excess of acid added, and the 3rd representing the conversion of the salt into the free alkaloid. Titrate alkaloid salts directly with KOH. The method is simpler than that using either the H electrode or the quinhydrone electrode.

L. E. WARREN

Chemical investigations of corpus luteum. III. On the presence of free amino acids in the acetone extract. M. C. HART AND F. W. HEYL. *J. Am. Pharm. Assoc.* **14**, 770-3(1925); cf. *C. A.* **18**, 1178.—In the follicular fluid of the sow the solids amount to 7.31%, of which 87% is protein. As the corpus luteum develops the protein is reduced to 40% of the dried material, which suggests enzymic action. Protein hydrolytic products such as peptides or amino acids would be expected. In the systematic examn. of the acetone ext. of corpus luteum cryst. material seps., the EtOH-insol part of which is shown to be a mixt. of the amino acids, leucine, isoleucine, and probably valine. The presence of amino acids in corpus luteum is to be expected in consideration of the change of follicular liquid, in which the protein part constituents predominate, to the corpus luteum, in which the protein part is greatly reduced.

Synthetic ammonia by catalysis. A. T. LARSON. *J. Chem. Education* **3**, 284-90 (1926).—A review. E. H.

Possible potash production from Minnesota shale. H. A. SCHMITT. *Econ. Geol.* **19**, 72-83 (1924).—S. describes the occurrence of the Decorah and Galena formations in the vicinity of St. Paul. Different sections show a K_2O content ranging from 5.04% to 8.24%, with an av. for 84 ft. of 5.96%. After a brief summary of previous work on the recovery and utilization of shale, S. discusses his work and gives his conclusions as follows: The potash is in 2 states of combination, 60% being more easily available than the rest. Much of the potash can be obtained from the shale by heat treatment with Na salts equiv. in amt. to the K and with a slight excess of $CaCO_3$. The K can be rendered sol. and in part volatilized from bricks where salt and $CaCO_3$ have been added to the raw shale. The shale is favorably situated for use in the manuf. of sand-lime brick or port. cement after extn. of the lime. The shale is being used without preliminary heat treatment as a fertilizer with considerable promise of success. C. W. C.

Use of sodium chloride in the manufacture of synthetic saltpeter. D. P. MANOIEV. *Trans. Inst. Applied Chem.* (Russian) **1925**, No. 4, 37-9.—In the manuf. of synthetic $NaNO_3$ either by oxidation of NH_3 or from air, the sources of Na used are NaOH or Na_2CO_3 . M. investigated whether NaCl could be used. This depends on the relative soly. of NaCl and $NaNO_3$ in acidified water: if pure $NaNO_3$ should ppt., the use of NaCl would have the advantage of cheapness over NaOH or Na_2CO_3 . With this in mind, M. studied the soly. of equiv. quantities of NaCl and $NaNO_3$ in acidified water. Conclusion: Either NaCl or a mixt. of NaCl and $NaNO_3$ is pptd. from acid solns., depending on the concn. of the acid. Thus the prepn. of $NaNO_3$ by M.'s method would require a purification of the saltpeter obtained, which could be done by recrystn.

BERNARD NELSON

Separation of aluminum sulfate from iron by means of alcohol. N. VITTOFF. *Trans. Inst. Econ. Mineral. and Petr.* (Russia) **1924**, No. 8, 1-16.—Bauxite from the region of Tichwinsk when treated with 50° BÉ. H_2SO_4 yielded over 99% of the Al_2O_3 . The mixt. of Al and Fe sulfates was treated with alc. (90%), which gave a hydrous Al sulfate with 0.1% of Fe. After the third pptn. with alc. the % of Fe was reduced to 0.0005%. The yield was 97% of the theoretical. The process was carried out on a lab. scale and its industrial application investigated. The theory of pptn. with alc. is discussed. An English résumé is given. J. S. JOFFE

Lead and zinc pigments and salts in 1924. C. E. SIEBENTHAL AND A. STOLL. U. S. Geol. Survey, *Mineral Resources of U. S. 1924*, Part I, 141-8 (preprint No. 11, published Feb. 12, 1926). E. H.

Bakelite in large chemical apparatus. H. LEBACH. *Z. angew. Chem.* **38**, 1091-4 (1925).—A discussion of the use of bakelite as a coating, and in the construction of chem. app., especially that used in corrosive acids, solns., etc. For these purposes it fills a long-felt want. Numerous illustrations of its use in (German) technology are given. W. C. EBAUGH

A noteworthy appearance of phosphine. W. STEFFENS. *Z. angew. Chem.* **38**, 1096 (1925).—Mortar at a certain place in an old building gave PH_3 upon treatment with H_2O . The formation was ascribed to the action of H_2O upon Ca_3P_2 , probably formed from the $Ca_3(PO_4)_2$ originally present by electrolytic reduction from a short circuit. W. C. EBAUGH

Aktivin. J. HAUSNER. *Pharm. Zentralhalle* **67**, 115-6 (1926).—A new accessory for use in connection with the adhesive industry, notably in bleaching dextrin, rendering starch sol. and possessing a germicidal value akin to $HgCl_2$, is $CH_3C_6H_4SO_2NCINa$, which decomps. in the presence of oxidizable material into *p*-toluenesulfoneamide, NaCl and O. W. O. E.

Mica in 1924. BLANCHE H. STODDARD. U. S. Geol. Survey, *Mineral Resources of U. S. 1924*, Part II, 171-81 (preprint No. 15, published Feb. 12, 1926). E. H.

Old Italian violin wood. C. G. SCHWALBE AND R. SCHOPP. *Z. angew. Chem.* **38**, 965-6 (1925).—It was noted that the wood of an old Amati violin showed practically the same compn. as that of modern Italian and German violins, so far as lignin, pentosans, etc., were concerned, but was higher in ash. To test out the legend that the old masters allowed violin wood to lie in running water (probably "hard") for many months, the authors treated violin wood with the cooling water from a lab. still for 80 days

and found that the ash content increased from 0.27% to 1.16%, almost paralleling results from the old wood. W. C. EBAUGH

The role of bicarbonates in dry fire extinguishers. C. GENTSCH. *Z. angew. Chem.* 38, 966(1925).—A dry extinguisher was used to put out a fire, the resultant powder deposit collected and analyzed. Whereas the original contents of the app. had 96.8% NaHCO_3 , that collected afterwards ran 97.0%. It was then found that talcum, MgO , etc., used in the same way as NaHCO_3 , were quite as effective. The formation of a dust cloud, and perhaps the lowering of the temp. by the compressed air used, are factors causing the fire to be extinguished. W. C. EBAUGH

The salt mass from the waters of the Sosnevskaia factory (PASTAGANOV, ZAITZEV)

8. Treating fumes from smelting Cu alloys [for recovery of ZnO] (Brit. pat. 237,232)
9. NH_3 from vinasses (U. S. pat. 1,576,427) 16. Device for dissolving caustic soda (U. S. pat. 1,574,561) 1.

- Rubber-lined shipping drum for acids. R. T. GRIFFITHS. U. S. 1,575,681, March 9.

Rubber-lined metal receptacle for acids, etc. E. H. RADABAUGH. U. S. 1,574,690, Feb. 23.

Portable acid-proof receptacle lined with rubber. R. M. WARNER. U. S. 1,575,660, March 9.

Ammonia synthesis. SYNTHETIC AMMONIA & NITRATES, LTD. Brit. 237,394, May 29, 1924. Catalysts for NH_3 synthesis comprize a ferrate or ferrite of a non-poisoning metal, *e. g.*, Ca, Ba, Mg and Mn. Ca ferrite may be formed by fusing mol proportions of lime and Fe_2O_3 and may be used for NH_3 synthesis under a pressure of 90 atm. and at a temp. of 500° .

Calcium cyanide. F. J. METZGER. U. S. 1,573,732, Feb. 16. Ca cyanide or other cyanides are formed by treating carbides with HCN . A compd. of the formula $\text{Ca}(\text{CN})_2 \cdot 2\text{HCN}$ may be obtained.

Heavy basic magnesium carbonate. B. B. GRUNWALD. U. S. 1,573,603, Feb. 16. CO_2 is introduced into a mixt. of calcined magnesite and H_2O and the resulting heat of reaction utilized to produce a product of the desired phys. properties, *e. g.*, for making molded heat insulation.

Light basic magnesium carbonate. B. B. GRUNWALD. U. S. 1,573,604, Feb. 16. A mixt. of heavy MgCO_3 and H_2O is heated, with accompanying agitation, to a temp. of not over 82° to cause expansion of the MgCO_3 to the desired degree. Further expansion is checked by adding cold H_2O .

Light basic magnesium carbonate. R. B. CROWELL. U. S. 1,573,632, Feb. 16. CO_2 is supplied for reaction with MgO in aq. mixt. until the ratio of CO_2 to MgO lies between 0.8 and 0.9 and the material is heated to not over 60° .

Lead carbonate. S. C. SMITH and CHEMICAL & METALLURGICAL CORPORATION, LTD. Brit. 237,308, Jan. 30, 1924. Pb chloride is converted into carbonate by suspending it in aq. NH_3 soln. and passing in CO_2 . Various details of ore treatment and preliminary treatment of solns. to recover different values are described.

Zinc carbonate, etc. S. C. SMITH and CHEMICAL & METALLURGICAL CORPORATION, LTD. Brit. 237,306, Jan. 29, 1924. ZnCl_2 solns. such as those obtained from ores are treated with BaCO_3 to obtain ZnCO_3 and BaCl_2 which on treatment with H_2SO_4 or a sulfate forms BaSO_4 and HCl or a chloride for further use in treating Zn ore. Various details are given for treating Pb-Zn ores.

Aluminum nitrate. T. MEJDELL and Ö. RAVNER. U. S. 1,575,634, March 9. In order to sep. Al nitrate from Fe compds., a hot soln. of Al nitrate is mixed with a relatively cold soln. of Al nitrate (at least one of the solns. contg. the Fe compds. to be sepd.) under such conditions of temp. and concn. that the Al nitrate crystallizes from the mixt.

Barium sulfate. K. EBERS. Brit. 237,268, July 17, 1924. Crude BaSO_4 is bleached by heating with H_2SO_4 in the presence of fluorspar which may be naturally present or may be added. A small proportion of niter or HNO_3 also may be added.

Complex fluorides. A. F. MEYERHOFER. Brit. 237,615, Dec. 20, 1923. Complex fluorides such as Na fluotitanate (but not including fluosilicates, fluoborates or ordinary double fluorides) are obtained by substituting for the Si or B compd. of a previously

proposed process a compd. of another element; *e. g.*, MgF_2 , NaCl and Ti fluoride are caused to react in very dil. HCl . Brit. 237,616 specifies the production of K fluosilicate from KF , SiO_2 and HCl ; and the production of Na fluoborate from B fluoride, NaCl and HF . Cf. *C. A.* 19, 2113.

Apparatus for curing and drying acid phosphate. E. H. ARMSTRONG. U. S. 1,576,022, March 9.

Fused silica. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 237,264, July 18, 1924. Plastic SiO_2 is extruded through an aperture to form a long rod which is cut into sections. The latter are allowed to cool while suspended at one end. An app. is described.

Zinc oxide. H. H. UTLEY and J. MCCALLUM. U. S. 1,574,317, Feb. 23. The Pb and other chloridizable constituents of fume products contg. Zn and Pb are chloridized and the chloridized material is sepd. by volatilization from the ZnO . The residue is mixed with coke breeze or other carbonaceous reducing material and the mixt. is roasted.

Oxides from sulfates. R. JACOBSON. Brit. 237,243, July 16, 1924. Sulfates such as those of Fe or Al (or alum) are heated *in vacuo* and the SO_3 formed may be converted into H_2SO_4 and employed to treat raw materials to form more sulfates. $\text{Fe}_2(\text{SO}_4)_3$ may be decomposed at 630° in a vacuum of 50 mm.

Sulfur from ores. C. MARX. U. S. 1,574,987, March 2. S is distd. from sulfide ores with the aid of a high vacuum and the S vapors are condensed. U. S. 1,574,988 specifies the similar distn. of S when present in ore in elemental form. Cf. *C. A.* 19, 3355.

Activating carbon. E. BATEMAN. U. S. 1,573,509, Feb. 16. Comminuted C , *e. g.*, anthracite or charcoal, is treated with CO_2 at temps. of 650 – 1000° .

Decolorizing-carbon. G. J. ESSELEN, JR. U. S. 1,575,561, March 2. A product for decolorizing and defecating purposes is obtained from the isolated pithy material of the sugar cane, associated with alk. material such as lime.

Decolorizing-charcoal. H. MÜLLER-CLEMM. U. S. 1,575,703, March 9. Sulfite waste lye or other carbonaceous material is carbonized in the presence of K sulfide or other alkali metal sulfide, to produce an active C .

Portable retort apparatus for producing activated carbon. J. N. A. SAUER. Brit. 236,984, April 5, 1924. The retort base may have mounted on it a generator for producing activating gas, *e. g.*, gas from crude oil or gasoline, and also app. for pre-distg. or charring the raw carbonaceous material.

Apparatus for making carbon or lampblack. O. D. HORTON. U. S. 1,574,091, Feb. 23.

Apparatus for bolting carbon black. W. C. CASSELL and C. K. SPRINGFIELD. U. S. 1,573,373, Feb. 16.

Composition for filtrations and other uses. H. A. ENDRES. U. S. 1,574,380, Feb. 23. A mixt. of finely divided siliceous material such as diatomaceous earth with lime and H_2O is heated and the resulting product is then calcined.

Preparing diatomaceous earth for filtering, decolorizing, etc. R. CALVERT. U. S. 1,574,363, Feb. 23. A mixt. of finely divided diatomaceous earth with lime and H_2O is heated to a temp. of about 90 – 105° .

Filter material. H. C. MARTIN. U. S. 1,576,440, March 9. A porous product comprises a compacted and baked mixt. of Si carbide or other mineral grains, moistened with furfural or other resin solvent, and a synthetic resin such as that produced from PhOH and formaldehyde.

Casein solids. A. A. DUNHAM. U. S. 1,575,155, March 2. Acid-pptd. casein, the acidity of which is materially above 0.75% free acid, is treated with a sufficient amt. of acid-neutralizing substances such as borax to reduce the acidity to 0.25 – 0.75% , and adapt the product for molding and machining.

Refining "pearl essence." J. BAISSÉAU. U. S. 1,576,454, March 9. The raw material is treated with a proteolytic compn. or other biological reagent which will cause a fermentation of the org. substances contg. the crystalloids and the latter are recovered from the dissolved products of the fermentation. Cf. *C. A.* 19, 1036, 3150.

Conditioning shoe-bottom filler compositions. G. H. MAXWELL. U. S. 1,573,353, Feb. 16. Filler material such as that comprizing comminuted cork and a sticky waxy binder is permeated with steam while being passed in non-compacted condition through gravity chutes to prep. it for use.

Felt for box toes of shoes. H. P. SHOPNECK. U. S. 1,574,208, Feb. 23. A fibrous pulp such as rag stock is felted with jute or other vegetable fibers of similar length and with asbestos and the material is impregnated with a thermo-plastic binder, *e. g.*, rosin and oil-blown asphalt.

Water-laid felt. H. P. SHOPNECK. U. S. 1,574,126, Feb. 23. A material suitable for use in shoes for box toes comprises rag or wood pulp or other fibrous pulp felted with longer fiber such as cut jute and impregnated with an asphaltic or other thermo-plastic binder.

Plastic compositions including phenolic derivatives. G. J. VOTAPEK. U. S. 1,574,771, March 2. The binding properties of reaction products of phenolic substances and halogen derivs. of S are improved (to adapt the material for better use in plastic compns. such as mixts. with fillers) by the addn. of a small proportion of stearin pitch.

Decomposition of silver for coating purposes. B. BART. U. S. 1,574,544, Feb. 23. A soln. of AgNO_3 or other Ag salt is mixed with a reducing agent such as formaldehyde or rochelle salt and the mixt. is maintained out of contact with the air and applied as a spray or mist to a surface to be coated before reduction of the Ag salt has been completely effected.

Semi-transparent coating. A. BENSON. U. S. 1,574,862, March 2. A coating adapted for use on wood, glass, clay, etc., comprises equal parts of magnesite, SiO_2 and infusorial earth fused together and a soln. of MgCl_2 .

Lamp wick. Z. OLSSON. U. S. 1,573,500, Feb. 16. Lamp wicks are impregnated with alum, $(\text{NH}_4)_2\text{SO}_4$ and oxalic acid to render them resistant to combustion.

Composite sheets of glass and celluloid. G. B. RILEY. Brit. 237,179, May 13, 1924. A sealing material used adjacent to the edges of the sheets comprises pitch, bees wax, or a varnish contg. celluloid 1, AmOAc 10, acetone 5, "methylated spirits" 5 and gum sandarac 2 parts.

Uniting sheets of glass and celluloid. G. B. RILEY. Brit. 237,379, May 13, 1924. Sheets of glass are cemented to opposite sides of a celluloid sheet by heat and pressure after treating the glass sheets with a soln. contg. "isinglass" and a dextrin gum and the celluloid sheet with a soln. of colophony and castor oil.

Composition for preventing accumulation of moisture on glass, etc. M. ROSS. U. S. 1,576,363, March 9. Sep. aq. gelatin solns. are treated with concd. HNO_3 and concd. chromic acid and then mixed.

Extinguishing fires. INTERNATIONALE FEUERLÖSCHER GES. Brit. 236,964, July 12, 1924. CO_2 or other fire-extinguishing gas is permitted to expand from the liquid form and the portion thus solidified is thrown on fires, *e. g.*, those of inflammable liquids.

Composition for cleaning stone, tile, etc. G. A. NELSON. U. S. 1,574,406, Feb. 23. NH_4F 95 and oxalic acid 5% $1\frac{1}{2}$ lbs. and H_2O 1 gal. U. S. 1,574,407 specifies a mixt. of NH_4F 75, oxalic acid 10 and Na_2CO_3 15% $1\frac{1}{2}$ lbs. per gal. of H_2O .

Friction material for lining clutches, etc. J. MACADAM and W. BERRY. U. S. 1,573,982, Feb. 23. A fabric similar to cotton belting is impregnated with cellulose, *e. g.*, by use of a viscose soln.

Composition for treating brake linings. F. E. WIESER. U. S. 1,573,468, Feb. 16, 1924. Turpentine 96, castor oil 16, graphite 8 and oil of citronella 1 part.

Colored bakelite screens for illuminated "imitation fires." CABLE ACCESSORIES CO., LTD. AND F. H. REEVES. Brit. 237,327, April 12, 1924.

Composition for protecting the hands from grease, etc. D. R. KELLOGG. U. S. 1,574,733, Feb. 23. Bentonite 17, soap 4.5 and H_2O 78.5%.

Coated stencil sheets. D. GESTETNER. Brit. 237,000, July 11, 1924.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

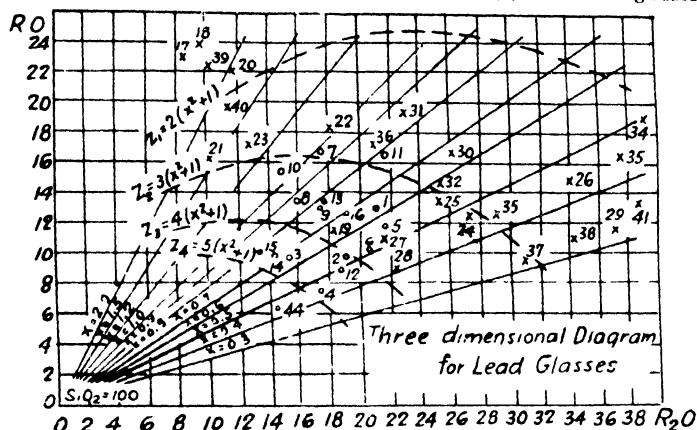

G. E. BARTON, C. H. KERR

Glass sands of Ohio. J. A. BOWNOCKER. *Ohio J. Sci.* 26, 25-41 (1926). The glass sands of Ohio are described as to occurrence, winning and prepn. Chem. analyses of over 100 sands are given, including washed and unwashed material, ganisters, steel sands, blast sands, etc. Only in one case does this material approach the specifications for first-class glass sand and in this instance the Fe content is too great. The other common impurities occur in considerable amounts. Ohio produces about 2% of the glass sand used in the U. S. H. F. K.

American glass sands, their properties and preparation. C. R. FETTKER. *Trans. Am. Inst. Mining Met. Eng.*, No. 1531-H, 25 pp. (Feb., 1926).—The effect of the chem. compn., fineness and size of grain on the value of glass sands is discussed. The Oriskany and St. Peter sandstones are the two major sources of glass sand in the U. S. W. Va., Ill., Penn., N. J. and Mo. in descending order produce over 80% of the glass sand of the country. The methods of winning and prepn. of this material are given. H. F. K.

The devitrification of glasses. K. TABATA, K. YEGAMI AND S. MORIYASU. *Researches Electrotech. Lab. Japan.*, No. 162, 28 pp.(1925).—Samples were taken from depleted and newly manufd. radio transmitting and receiving bulbs whose previous histories were unknown. They were exposed to temps. between 600° and 1000° and observed macroscopically and microscopically for their devitrifying temp. Results of chem. analysis on each glass also are given. It is quant. shown that there are close relations between the chem. compns. and the mode of devitrification of glasses upon heating.

Lead glass and the glass formula. O. KNAPP. *Sprechsaal* 57, 512(1924); *J. Soc. Glass. Tech.* (Abstracts) 9, 112-3.—A graphical study of glass composition based on Tschuschner's formula. A table was given of data for 44 glasses. On the graph the small circles indicated technical glasses, and the small crosses optical glasses. The lines $z = \alpha(x^2 + 1)$, $x = 0.3$ to 2.0 were inserted, using the notation of Tschuschner. The following conclusions were drawn: (1) Lead glasses had either the normal formulas of Tschuschner, or the wider form of general value. (2) Technical glasses were in

two groups, (a) normal, with z between z_1 and z_2 ; (b) hard, with z between z_3 and z_4 . (3) Optical glass varied, but, from examples examined, $2(x^2 + 1) < z < 5(x^2 + 1)$. (4) Soda glasses preponderated above z_1 ; mixed alkali glasses between z_1 and z_3 and potash glasses at z_4 . (5) The limits of molecular composition were: 0.0 to 2.8 alkali:1PbO:0.8 to 14.2SiO₂. These limits were bigger than with lime-glass, and a resistance glass which was rich in lead contained less silica than indicated by $z = 2(x^2 + 1)$. H. G.

Keppeler's rule for lead glasses. O. KNAPP. *Sprechsaal* 58, 110(1925); *J. Soc. Glass Tech.* (Abstracts) 9, 113.—Keppeler's rule for the compn. of stable Pb glasses stated that the relative no. of mols. of silica in excess of the no. of mols. of Pb oxide should be from 6 to 8 times the no. of alkali mols. present. Thus, if the mol. formula of the glass were $xR_2O.yPbO.zSiO_2$, then $8x > z - y > 6x$. A diagram gives the relative values of x to $z - y$ for a large no. of known Pb glasses. For the rule to be correct the points should lie between lines which represent the ratios $z - y = 6x$ and $z - y = 8x$, resp. The bulk of the values lay outside these lines and could only be contained by lines representing $12.5x > z - y > 3x$. H. G.

The construction of the composition of glasses and glazes. H. HERMANN. *Sprechsaal* 58, 15(1925); *J. Soc. Glass Tech.* (Abstracts) 9, 102.—Since devitrification resulted in the deposition of definite compds. it was natural to attempt to arrange glass compns. in the form of amts. of silicates. For the acid alkali-lime glasses (mirror-glass group) and the ordinary alumina-contg. glasses (bottle group), consideration of the products of devitrification led to the calcn. of the relative amts. of metasilicates, aluminosilicates of the nepheline type, alkali silicates, and free silica. Thus, for a green bottle glass:

	Percentage compn.	Mol. compn.		Percentage compn.	Mol. compn.
SiO ₂	63.76	1.061	CaO	15.75	0.281
Al ₂ O ₃	9.58	0.094	MgO	0.67	0.017
Fe ₂ O ₃	1.92	0.012	K ₂ O	3.06	0.033
MnO	0.32	0.004	Na ₂ O	5.10	0.082

By equiv. division the mols. present would be:

0.019 FeSiO ₃	0.005 FeO			
0.003 MnSiO ₃	0.001 MnO			
0.222 CaSiO ₃	0.059 CaO			
0.013 MgSiO ₃	0.004 MgO	Al ₂ O ₃ .2SiO ₂	0.064 Na ₂ O	0.616 SiO ₂
	0.007 K ₂ O		0.027 K ₂ O	
0.257	0.018 Na ₂ O		0.091	
	0.094			

and this could be calcd. to the proportions in which Na₂O + K₂O 1 in the usual way, giving:

0.21 FeSiO ₃	0.06 FeO			
0.03 MnSiO ₃	0.01 MnO			
2.44 CaSiO ₃	0.64 CaO			
0.14 MgSiO ₃	0.04 MgO	Al ₂ O ₃ .2SiO ₂	0.70 Na ₂ O	6.71 SiO ₂
	0.08 K ₂ O		0.30 K ₂ O	
2.82	0.20 Na ₂ O		1.00	
	1.03			

These results should not be taken too literally, since they do not take into account the possibility of assocn. or dissocn. A mathematical discussion of the usual expression for the evaluation of phys. properties in the form of a linear function of the oxide percentages ($A = a_1x_1 + a_2x_2 + \dots$) showed that it could be transformed into a similar expression in terms of silicate percentages.

The determination of boric oxide in glass. K. TABATA AND S. MORIYASU. *Researches Electrotech. Lab. Japan*. No. 153, 32 pp. (1925).—As Chapin's method for detg B₂O₃ in glass is tedious because of the high content of water in the soln. and the inadequacy of the dehydration action of CaCl₂ at the temp. of evapn., T. and M. improved the distn. app. by using paraffin bath instead of ordinary water bath and modified the manipulation by adding MeOH after evapg. the soln. to a sirupy state. Evap. the contents of the flask at about 140°, cool to 40–50°, add MeOH, heat to 80° and finally to 110°. When the vol. of the soln. becomes about that of original, cool to 50–40°, add another portion of MeOH and repeat the same operation 3 times in all. With this improved operation the time necessary for distg. as methyl borate is shortened by half.

The production of colorless glass in tank furnaces with special reference to the use of selenium. III. The influence of arsenious oxides and other constituents of the batch. A. COUSEN AND W. E. S. TURNER. *J. Soc. Glass Tech.* 9, 119–27 (1925); cf. *C. A.* 18, 1736.—As₂O₃ is a necessary factor in the decolorizing of the glasses examined by Se, the amt. needed being at least 30 times that of the Se.

A note on the changes of color of selenium glasses during annealing and reannealing and by exposure to light. A. COUSEN AND W. E. S. TURNER. *J. Soc. Glass Tech.* 9, 111–7 (1925).—Glasses contg. 1000 parts sand, 200 limespar and 370 soda ash with small addns. of Se showed color changes on reheating to 500–625° only when distinct tints were originally present, thus confirming the earlier work of C. and T. (cf. *C. A.* 17, 1536). Exposure to sunlight for 13 months reversed the changes produced by reheating.

An attempt to improve the qualities of glasses intended for lamp-working purposes. W. E. S. TURNER. *J. Soc. Glass Tech.* 9, 133–47 (1925).—Leadless glasses of narrow compn. limits were sent to lamp-working firms to be used in comparison with their present types. The phys. properties and resistance to hot H₂O and to narcotine-HCl were detd.

Post-war apparatus glasses. H. THIENE. *Z. angew. Chem.* 39, 193–4 (1926). Resista glass vessels, as Pyrex imitations, are not found to be superior to Jena-glass articles for general lab. use as detd. by resistance to thermal shock, boiling H₂O, and dil. H₂SO₄. Jena glassware lost only half as much in wt. during boiling with 2 N NaOH soln. as did Resista vessels of similar type.

Pollapas. H. R. SCHULZ, R. SCHMIDT AND L. SCHMIDT. *Keram. Rundschau* 33, 143 (1925); *J. Soc. Glass Tech. (Abstracts)* 9, 104–5.—H. R. Schulz did not attach great importance to "Pollapas," discovered by F. Pollak and R. Ripper of Vienna, because of its disadvantages. It was too soft for window glass, while its inflammability prevented its use for illuminating ware. The low hardness coupled with the small sta-

bility of resin-like materials towards org. acids, alc., etc., precluded its use for chem. ware. The materials from which Pollopas could be made were far more restricted than those from which glass could be produced, limiting the range of variation of properties of the former as compared with the latter material. Samples of Pollopas had not the same homogeneity and freedom from strain as had articles made from glass. R. Schmidt, while pointing out some of the possible uses of the material, also emphasized some of the difficulties involved in its employment. Pollopas had a n similar to that of flint glass (n_D 1.54 to 1.90), and although it could be employed for small lenses it was so soft as to be easily scratched. The material had the following mech. properties as compared with glass and other materials:

	Glass	Juvelith	Pollopas	Iron	
Compressive strength	60—130	11.7	22.3	20—90	} kg. per sq. mm.
Tensile strength	3—9	6	10	9—50	
Bending strength	—	2.5	5.1	—	

For objects made on the lathe, the new material would probably be very suitable, while its non-brittle nature made it suitable for motor-car windows, etc. Although stable to water in the cold, it swelled somewhat on heating, and by heating with an org. coloring agent in a weakly alk. soln. it could be suitably colored in the surface layers. For this reason it could be used for light-filters, while it gave good imitation opal glass and porcelain. The cond. of heat of Pollopas was 0.00184 (glass 0.00108 to 0.00227) and the material was a good elec. insulator. H. G.

Crystals in stalactites from glass kilns. N. N. SMIRNOV. *Trans. Inst. Exp. Silicates* (Russian) 1924, No. 16, 9—17.—Examination of the stalactites showed them to be cryst. They may be placed with the tridymites. J. S. JOFFE

Stalactites from the continuous glass kilns. B. S. SHVETZOV. *Trans. Inst. Exp. Silicates* (Russian) 1924, No. 16, 5—8.—The mechanism of formation of stalactites during the time of cooling the kilns for repairs and their chem. compn. are given. J. S. JOFFE

Tank control and devitrification. H. INSLEY. *Glass Ind.* 7, 1(1926).—A triaxial diagram of the system $\text{SiO}_2\text{--CaO--Na}_2\text{O}$ is the principal feature of this article. Typical soda-lime glass compns. for various purposes are shown on the diagram. The compns. of the compds. which crystallize out, thus causing devitrification, in each case, are connected by dotted lines to these various points. Devitrification can always be prevented by raising the temp. sufficiently at the place where it starts. Where this is impossible, the crystg. temp. can be lowered by slightly changing the compn. of the batch in a direction away from the compd. which crystallizes. E. G. J.

Pulverized fuel for glass furnaces. O. MAETZ. *Sprechsaal* 58, 151(1925); *J. Soc. Glass Tech.* (Abstracts) 9, 133.—The advantages of using pulverized fuel were a saving in wages, use of inferior fuel, easy regulation of temp. and of flame conditions, and actual heat economy. The disadvantages were necessity for a special drying and pulverizing plant, high temp. in the ignition chamber, and possible contamination of the glass by ash. A calcn. was given showing that the saving over briquets was 59%, and that with 10% excess air, a theoretical temp. of 1860° was possible. Further, there was sufficient waste heat to operate a lehr and to raise steam. A plea was made for the trial of pulverized fuel in the glass industry. H. G.

Recuperation increases capacity of English tanks. F. W. HODKIN and W. E. S. TURNER. *Ceram. Indus.* [2] 4, 106(1925); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 127—8.—The air for combustion is preheated first by passage through the flues, the arches of which support the bottom of the tank, and which are superimposed on other flues through which the products of combustion pass in an opposite direction. The air is preheated further by passage through the space between the false crown and the main crown of the furnace. One advantage claimed for this type of furnace is the reduction in the cost of construction by the reduction of the excavation needed due to the absence of regenerators. Approx. 0.8 of a ton of coal is consumed by the producers and boilers per ton of finished glassware. Another unique feature of the tank is the double bridge; this has 3 walls sepd. by cavities through which steam is blown for cooling the blocks. The life of the bridge blocks is very much longer. The bridge inspected had been in operation without repair for 14 months. H. G.

Viscosity determinations in ceramics. E. P. BAUER. *Trans. Ger. Ceram.* Soc.* 5, 2(1924); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 18.—Describes the patented Fischer-Bauer viscometer, in which is measured the speed of descent, through the clay slip, of a known spherical wt. almost counterbalanced by another, outside wt. To obtain

true viscosity the results are compared with a standard like glycerol. $V:V' = ST:S'T'$, where T and $T' =$ time and S and $S' =$ sp. gr. of the liquids. H. G.

A chemical study of the absorption of sulfur dioxide from kiln gases by ceramic wares. F. G. JACKSON. *J. Am. Ceram. Soc.* 9, 154-73(1926).—Two clays, rich in scum-forming bases were studied. One was practically free from S, the other rich in S. Draw trials of both clays were taken at suitable temp. intervals from both lab. and com. kilns. Comparisons of results showed that the temp. attained has much more influence upon the amt. of sulfates formed in the ware than concn. or time of S exposure. Calcs. show that even under most favorable firing conditions, with 0.5% S coal, on a 64-hr. schedule of firing, 12 times as much S is available as is actually absorbed. Further analysis also shows that it is futile to try to avoid sulfate formation, with coal as fuel, by seeking a low-S coal. C. H. KERR

Analyses of pottery from the Gallic "oppidum de Vindalium" (Vaucluse). LOUIS DESVERGNES. *Ann. chim. anal. chim. appl.* 8, 40-1(1926).—The analyses of 2 very old samples are given. W. T. H.

Modern pottery equipment. G. L. MONTGOMERY. *Chem. Met. Eng.* 33, 142 G (1926).—The plant of Thomas Maddock's Sons Co., Trenton, N. J., is described. E. H.

The influence of grain size on the solubility of quartz in feldspar in porcelain fire. KURT WETZEL. *Trans. Ger. Ceram. Soc.* 5, 2(1924); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 137.—Quartz grains of uniform size are dissolved at a uniform rate by melting feldspar. In the series potash spar-quartz the soly. of the coarsest-grained quartz used was 95%, rising gradually to 100% for the finest grains. If a mixt. of grains is used the finest will be completely dissolved and the coarser ones only partially. Practically no difference in soly. was noted between Hohenbocka sand and Norwegian quartz. Different grades of feldspar showed more marked variation. Norwegian feldspar has a higher soly. than soda feldspar from N. Bavaria. Addn. of strong flux such as CaO or MgO increases the soly. A comparison between the soly. of feldspar and a porcelain body showed close similarity. H. G.

Refractories for gas retorts, with special reference to silica. W. EMERY. *Appendix II.* A. SCOTT. *Trans. Ceram. Soc. (Eng.)* 24, 361-401(1925).—A comparison of SiO₂, siliceous and clay refractories, especially as to duration, is made from the inspection of some gas works. The conversion of quartz into cristobalite and the formation of sillimanite (mullite?) are followed in unused and used gas retorts with photomicrographs. H. F. K.

Articles made of molten magnesite. J. BRONN. *Chem.-Ztg.* 49, 1053-4(1925). The difficulties encountered in the manufacture and use of articles made of molten magnesite are described. H. F. K.

Temperature-load determinations and their possibilities. HANS HIRSCH. *Trans. Ger. Ceram. Soc.* 5, 3(1924); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 140.—Describes tests made with a Steger lever press and a new app. developed in the "Laboratory for Clay Industries," Berlin. These both have a sensitive recording device. Small test pieces having a cross-section of 8 sq. cm. were used and heated in an elec. furnace with a temp. advance of 4-5° per min. Pressures used were 1 kg. per sq. cm. for silica brick and 2 kg. per sq. cm. for clay brick. Numerous charts show the behavior of widely different refractory bodies and kaolins. Those with increasing Al₂O₃ content showed a more gradual softening range. Refractories high in SiO₂ showed a preliminary expansion and then a rapid softening. Kaolin showed an irregular curve, indicating a retardation in the softening at certain stages. H. G.

Reddish discoloration of opaque tin oxide glazes. R. RIEKE. *Trans. Ger. Ceram. Soc.* 5, 2(1924); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 25.—The research lab. of the State Porcelain Works, Berlin, traced the discoloration to a small quantity of chrome salts present in the Pb₃O₄, the characteristic bright red color of which had been preserved by the addn. of org. coloring matter. The quantity present was too small to be revealed by analysis and on investigation it was found that as low as 0.0025% Cr₂O₃ led to a decided discoloration. On this account Pb₃O₄ should be closely watched for traces of Cr. Tests also showed that the discoloration developed under oxidizing conditions and disappeared if the glaze was subjected to a reducing atm. H. G.

A practical gas-fired test furnace for plant use. H. G. FISK. *J. Am. Ceram. Soc.* 9, 151-3(1926). C. H. KERR

The design of arches for kilns and furnaces. F. H. NORTON. *J. Am. Ceram. Soc.* 9, 144-50(1926). C. H. KERR

Progress report on investigation of sagger clays. R. A. HEINDL. *J. Am. Ceram. Soc.* 9, 131-43(1926).—A first progress report of a comprehensive study of sagger clays

Chem. analyses, phys. tests, petrographic data and the effect of repeated burns in pottery kilns are given. The clays are classified into 5 groups in accordance with properties in the fired state. Further study is outlined.

C. H. KERR

Investigations leading to the discovery of the cause of excessive sagger breakage. W. STEGER. *Trans. Ger. Ceram. Soc.* 5, 3(1924); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 136.—Three main causes are (1) use of unsuitable raw materials and unfavorable batch compn.; (2) imperfect prepn. of the batch; (3) improper firing. This article also covers the investigation under (1) and (2).

to temp. changes and it is therefore important that in the initial firing all the free SiO_2 is taken into soln. The tests brought out that all clays contg. free SiO_2 have certain crit. temp. ranges in which they are more susceptible to temp. changes on account of the changes of the quartz to other forms. The extent of the vol. changes involved is dependent on the grain size and crystal nature of SiO_2 -bearing material, the finer the grain the greater the change in vol. Materials suggested to take the place of quartz are materials with high Al_2O_3 content, SiC and natural sillimanite.

H. G.

How whitewash can be prevented. H. C. MEYER. *Brick & Clay Record* [2] 66, 128(1925); *J. Am. Ceram. Soc., Ceram. Abstracts* 8, 132.—The causes of scumming are given and a method of testing for sol. sulfates is outlined. The BaCO_3 treatment for the prevention of whitewash or scum is considered the most reliable. Natural BaCO_3 is quite as satisfactory as pptd. BaCO_3 and is considerably cheaper.

H. G.

An accelerated abrasion test. C. H. GEISTER. *J. Am. Ceram. Soc.* 9, 121-5 (1926).—A new, simple abrasion app. is described. An upright, leather wheel rolls on a path of test samples placed on a horizontal revolving disk. There is const. slippage. Sand is fed mechanically. Check tests on various materials show the value of the test.

C. H. KERR

Certain clays from the productive series near Moscow (SMIRNOV) 8. Oven for heat-treating ceramic articles (U. S. pat. 1,573,873) 1.

Apparatus and heat-distributing method for melting glass batch ingredients. R. R. SHIVELY. U. S. 1,575,514, March 2.

Improving the color of clay or other earthy minerals. W. FELDENEHIMER. U. S. 1,573,385, Feb. 16. An aq. suspension of clay or similar material is treated with NaHSO_3 or other acid sulfite in the presence of Zn or other metal which reduces H_2SO_3 and does not form colored oxidized salts.

Fire brick. R. A. DALTON. U. S. 1,573,482, Feb. 16. The body portion of fire brick is formed of slag from a high-temp. forced-draft furnace which is free from ashes, a fire cement which sets hard at atm. temp. and a facing compn. for the brick comprises comminuted carborundum, fire cement and port. cement.

Tunnel kiln adapted for burning clay products. H. W. WEBER and A. O. SCHLEIFERTH. U. S. 1,575,470, March 2.

Tunnel kiln and sagger carrier, adapted for heat treatment. F. A. J. FITZGERALD. U. S. 1,573,543, Feb. 16.

Refractory brick for furnace linings. O. ARAM. U. S. 1,576,021, March 9. A superficial coating of metallic Al is applied to the exposed surfaces of linings of high-temp. furnaces.

Abrasives. D. E. WEBSTER. U. S. 1,576,122, March 9. Abrasive grains are bonded (to form grinding wheels or other articles) by the use of a heat-set phenol-formaldehyde condensation product combined with plaster of Paris forming 0.5-30% of the entire mass.

Abrasive articles. M. L. HARTMANN. U. S. 1,573,400, Feb. 16. A raw mixt. of abrasive grains and bonding material is mixed with comminuted oak wood or other non-volatile org. substance which does not have any tendency to swell during heating, and the mixt. is pressed into shape and burned. Cf. C. A. 20, 1310.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Anhydrite and gypsum cements. P. P. BUDNIKOV AND M. E. LEVINE. *Trans. Inst. Exp. Silicates* (Russian) 1924, No. 14, 1-31.—B. and L. discuss the theories concerning setting of plaster of Paris and show how to prep. such materials from natural gypsum without previous heating. The natural gypsum is ground fine and a catalyzer is added which helps the setting properties. NaHSO_4 is used as the catalyzer.

J. S. JOFFE

Digest of literature on methods of making flexure and tension tests of concrete. D. A. ABRAMS. *Proc. Am. Soc. Testing Materials* 25, Pt. I, 205-8(1925). A. P.-C.

Proposed tentative purchase specification for concrete aggregates. Report of Committee E-5. *Proc. Am. Concrete Inst.* 1926, (preprint). J. C. WITT

Transverse testing of concrete. H. F. CLEMMER AND F. BURGGRAFF. *Proc. Am. Concrete Inst.* 1926, (preprint).—The importance of transverse tests of concrete in highway construction is discussed and a transverse testing machine developed by the Illinois Highway Testing Lab. is described.

J. C. WITT

The effect of varied curing conditions upon the compressive strength of mortars and concretes. H. J. GILKEY. *Proc. Am. Concrete Inst.* 1926, (preprint). J. C. WITT

Extensibility of concrete. W. K. HATT. *Proc. Am. Concrete Inst.* 1926, (preprint).—A series of measurements of the shrinkage and expansion of 1:2:3 concrete (gravel aggregate) under various conditions of exposure were made. The ability of plain concrete and of concrete having fabric reinforcing from 0.26 to 0.33% to undergo extension without the appearance of surface fissures was studied. Fissures were classified as (a) microscopic—about 0.0004 in. in width, and (b) visible without magnification, about 0.0015 in. in width. The general conclusion is that mesh reinforcement will postpone the appearance of visible fissures, and lessen the defects arising from poor strength and curing. Additional tests are under way.

J. C. WITT

Control of concrete mixtures on University of Pittsburgh stadium. W. S. HINDMAN. *Proc. Am. Concrete Inst.* 1926, (preprint). J. C. WITT

Effect of lime on concrete products. P. C. CUNNICK. *Proc. Am. Concrete Inst.* 1926, (preprint).—In general the results of nearly 2000 specimens varying in mix, lime content, age, curing conditions, etc., indicate (1) the appearance of the product is improved by all percentages of lime; (2) up to 40% by weight, hydrated lime gives an av. increase in strength of approx. 1% for each lb. of lime added per sack of cement; all percentages of lime tested showing increase in strength from 28 days to 6 months; (3) absorption is increased, as detd. by the standard immersion method, but not increased as detd. by impounding water on 1 face; (4) permeability as detd. by impounding water on 1 face is eliminated by using 20% or more of hydrated lime; and (5) penetration of dampness into the product decreases as the lime is increased.

J. C. WITT

Destructive agents and protective treatments. Report of Committee E-6. *Proc. Am. Concrete Inst.* 1926, (preprint).—A report on the examn. of several cases of concrete disintegration.

J. C. WITT

Soaps as integral water-proofings for concrete. A. H. WHITE AND J. H. BATEMAN. *Proc. Am. Concrete Inst.* 1926, (preprint).—Soaps added in the concrete mixer are effective in preventing the absorption of water by capillary action—as little as 0.05% fat acid (on the basis of the wt. of concrete) being sufficient. The strength is not impaired by the presence of soaps in such small quantities, provided the concrete is kept damp continuously until it has attained the desired strength, and provided the soaps have not caused foaming and entrainment of air. Soaps will not prevent the penetration of water through cracked concrete, but they will retard the penetration of water into dry concrete. If concrete is kept damp until properly cured there should be only slight diminution in strength due to water-proofing, and conditions may arise in service when the strength is increased. For example, a concrete slab wet and expanded on one side and dry and contracted on the other is subject to powerful shearing stresses which weaken it materially. This condition is improved by water-proofing.

J. C. WITT

Testing standard building units. Report of Committee P-1. *Proc. Am. Concrete Inst.* 1926, (preprint).—Proposed additions to the present specifications. J. C. WITT

The importance of sublimate as material for wood impregnation. R. FALCK AND S. MICHAEL. *Z. angew. Chem.* 39, 186-93(1926).— HgCl_2 is not an ideal impregnating material for wood since it does not penetrate deeply and quickly into the inner

cells but forms an exterior coating which can be removed by is much superior in this respect. HgCl_2 is only slightly reduced lose. HgCl_2 is physically held and does not enter into chem. wood fibers. The addn. of NaCl to the impregnating soln. re HgCl_2 taken up by the wood while NaF does not affect this action of Hg are not chemically held and can be removed by washing.

Marine wood destroyers and their control. F. ROCIL. *Z. ver. deut. Ing.* 70, 89-96(1926).—Abstract of Rept. of Danish Eng. Soc. Copenhagen, May, 1921, on investigation of *Teredo* and *Limnoria* injury on the Scandinavian coasts, printed in *Ingeniren* 41. The report covers: geographical distribution; effect of salinity, temp and pollution of sea water; immunity of certain woods; protection of piles by means of surface coatings, armor and impregnation with creosote; bibliography. A. L. K.

Testing of roofing paper (HERZBERG) 23. Electrolytic cell operation in production of roofing sheets coated with Cu or other metal (U. S. pat. 1,574,446) 4. Electrolytic cell adapted for making roofing sheets with a Cu coating (U. S. pat. 1,574,385) 4.

SMITH, HUBERT SHIRLEY AND CROSTHWAITE, CHARLES DOVETON: **Cement Mortars.** London: The Institution. 19 pp.

Cement. L. SINDIC. Brit. 237,515, Feb. 20, 1925. CaCl_2 for promoting hardening (e. g., 2½-3%) is added to dry cement before, during or after grinding of the clinker "High-temperature cement." P. G. WILLETS. U. S. 1,573,888, Feb. 23. A cement adapted for sealing annealing leers comprizes BaSO_4 60, SiO_2 40 parts and Na silicate soln. of 43° Bé. to form a pasty mixt.

Burning cement. J. J. HENDRICKX and ETABLISSEMENTS POLIET ET CHAUSSON. Brit. 237,182, Feb. 23, 1925. Fuel supplied to a rotary kiln is mixed with sufficient lime or limestone to convert its ash into a cement corresponding in compn. to that produced in the kiln.

Monolithic pavement formed of cement, paving blocks of different thicknesses, etc. H. E. FLETCHER. U. S. 1,573,923, Feb. 23.

Bituminous concrete. PRODER SOC. ANON. AND M. LEVY. Brit. 237,010, April 16, 1924. Mixts. are prepd. from graded fillers and a pitch specially prepd. to exhibit a suitable hardness under penetrometer tests as described in Brit. 228,257 (C. A. 19, 2872); e. g., broken stone 450 may be mixed with sand 380, powd. mineral 300, and oil pitch (which has been steam-distd. at about 340° under a pressure of 4 mm. Hg) 100 parts.

Artificial stone. C. STEED. U. S. 1,573,425, Feb. 16. Particles of Na_2CO_3 or other sol. substance are coated with paraffin or other insol. material, embedded in plaster of Paris or similar plastic material, and, after the latter has set, the coating material is broken and the sol. substance dissolved away to produce an "artificial travertine" finish.

Material for light porous walls. C. MARCZINCZEK. U. S. 1,574,252, Feb. 23. Volcanic ash 40, lime ("hard wall finish") 20, pumice stone 20 and plaster of Paris 20% by vol.

Applying plaster or stucco. W. H. ALTON. U. S. 1,573,896, Feb. 23. Walls, ceilings or other surfaces to be coated are first given a viscous bituminous coating, gravel or other granular material is embedded and plaster is applied to the rough coating thus prepd. after it has hardened. U. S. 1,573,897 specifies mixing the granular material with the bituminous compn. in forming the underlying coating.

Asphaltic paving material. F. E. GREENE. U. S. 1,576,045, March 9. Steam-refined asphalt is heated to about 120-150°, mixed with aggregate and limestone (the latter in excess of the asphaltic material) and the mixt. is agitated and cooked at temps. of about 250-315°.

Highway surfacing. J. H. AMIES. U. S. 1,575,957, March 9. Common earth and mineral substances are heated in a rotating cylinder to about 1100°. Another batch of similar materials is mixed with a small proportion of CaO , in a slaking condition, a portion of the highly heated material is added, and about 12% of highly heated bituminous material is also added.

Felt fabric. R. H. JOHNSON. U. S. 1,574,896, March 2. Sheets suitable for floor coverings are formed of felted cattle hair and a binder including "tapioca gum" and latex.

Roofing felt. F. H. CLARK. Brit. 237,499, Dec. 31, 1924. Rag fiber felt is satd.

with a boiling mixt. of 75% bitumen and 25% pitch, the surplus is removed and after cooling the material is painted with a mixt. of bitumen 60, ochre 15, and "white spirit" 25%.

Waterproof sheets for roofing, etc. W. T. HOFMANN. U. S. 1,574,890, March 2. A felted or similar sheet material is passed through a waterproofing agent and the coating is then roughened by the action of an air blast and further coated with granular surfacing material.

Sheet mastic. F. R. MULLER. U. S. 1,575,378, March 2. Ingredients such as roofing tile compns. contg. rubber are heated and mixed, passed through chilled forming rolls, squeeze rolls and a water bath.

Preserving wood. R. LEEDOM. U. S. 1,574,662, Feb. 23. The surface of wood is charred to produce a dry hot char and a preserving material such as coal tar creosote is applied to the hot surface.

Preserving wood. H. NEUBAUER. U. S. 1,576,209, March 9. An aq. soln. formed from rock salt or other preservative salt is mixed with a plaster or concrete or similar cementitious material and the mixt. is applied as a coating layer on wood.

Treating wood or other surfaces to render them impervious. D. C. ATKINS. U. S. 1,575,521, March 2. The surface of wood, metal, concrete or other materials is treated with S chloride dissolved in gasoline and mixed with linseed oil, to render it resistant to H_2O , oil, acids and alkalies.

"Wood substitute." I. NAYLOR. U. S. 1,573,734, Feb. 16. Corn stalk material, bagasse or other waste vegetable fibrous material is used with a binder of Na silicate. The product is treated with hot air, CO_2 and $NaHCO_3$. Cf. C. A. 19, 1483.

A. C. FIELDNER

Review of studies on coal published in 1923-5. D. J. W. KREULEN. *Bull. féd. ind. chim. Belg.* 4, 533-46(1925).—Bibliographical. W. B. PLUMMER

Brown-coal research and the art of combustion. WILHELM DE LA SAUCE. *Feuerungstechnik* 13, 117-22(1925).—A review of recent German progress, including spontaneous combustion, boiler and locomotive firing, household use, powd. coal, coking and producers. ERNEST W. THIELE

The coal-mining industry of China. C. Y. WANG. *J. Assoc. Chinese Am. Eng.* 6, No. 10, 2-6(1925).—A survey includes analyses of typical coals and statistics on the uses of coal in China. W. fixes the coal reserve of China at 100,000,000,000 tons. WM. H. ADOLPH

The testing of coal. FRANK DAWSON. *Eng. Rev.* 37, 355-8(1924); *J. Inst. Metals* 33, 555.—The method of making a proximate analysis and detn. of calorific value of coal is described. H. G.

The mechanism of fusion of coals. ÉTIENNE AUDIBERT. *Compt. rend.* 182, 316-8(1926).—The effect of a high rate of heating is to lower the fusion point of the coal. The following data represent the origin of the sample, its % volatile matter, the fusion point under rapid heating (sample plunged in hot heating bath), and that under slow heating (controlled at $1^\circ/\text{min.}$). Anzin, 25%, 335° , 370° ; Lens, 30%, 325° , 360° ; Béthune, 36%, 345° , 370° ; Couriot, 21%, 420° , infusible; Grosménil, 25%, 415° , infusible; Bruay, 42%, 365° , infusible. Since the low rate of heating is approx. that present in com. coke ovens, the latter 3 coals would be classed as non-coking coals, although by heating sufficiently rapidly to give fusion, and subsequent carbonization of the fused mass, the final coke has approx. the same strength, d., etc., as that from the "coking" coals. W. B. PLUMMER

Froth flotation of coal. F. B. JONES AND A. M. JONES. *J. Chem. Met. Soc. S. Africa* 26, 125-38(1925).—A review of British tests on coal cleaning by flotation, and discussion of plant app. and operations. W. B. PLUMMER

By-product processing of coal. H. W. BROOKS. *Mech. Eng.* 48, 233-9(1926).—A review of various low-temp. carbonization processes, viz. the Doherty, Parker, Rolle (brown coal), MacIntire, Piron, Fusion, Thyssen (rotary), Hood-Odell (lignite), MacLaurin, Nielson and McEwen-Runge. Illustrations and brief descriptions are given. W. B. PLUMMER

Origin of carbon disulfide in the carbonization of coal. W. J. HUFF. *Ind. Eng. Chem.* 18, 357-61(1926).—Expts. and app. are described in detail. No evidence in support of the theory of the formation of CS_2 as the sec. reaction product of H_2S

and hot coke is found, it being shown that the CS_2 which may be found in such tests comes from the reheated coke itself. Even in small quantities coal gives appreciable amts. of CS_2 if heated rapidly, although slow heating and free gasification give only H_2S . The interpretation and application of the results are discussed at some length.

W. B. PLUMMER

Spontaneous combustion in the Warwickshire thick coal. I. The application of gas analysis to the detection of heatings. C. E. MORGAN. *Colliery Guardian* 131, 251-2, 316-8(1926).—Analyses of the return air afford an indication of the development of a heating in its early stage, at times even before it can be detected otherwise. The development of a serious heating is always characterized by a variation in the compn. of the return air. A progressive increase of the CO/O_2 ratio and a progressive decrease of the CO_2/O_2 ratio should be interpreted as an indication of heating. A decrease of both the CO/O_2 and CO_2/O_2 ratios indicates oxidation other than that of the coal, possibly pyrites. When heating is absent, the CO/O_2 ratio rarely exceeds 0.30, though a progressive change is of more significance. Discussion. *Ibid* 385. C. C. D.

Contribution on the efficiency of a coal-gas generator. V. IZHEVSKIL. *J. Russ. Met. Soc.* 1925, Pt. 1, 245-55.—This is a description of modified Clement gas generator whose efficiency was raised from 70 to 90%.

J. S. JOFFE

Firing brown coal. ADOMEIT. *Feuerungstechnik* 13, 128-37(1925).—A. describes and illustrates 13 types of German furnace and grate installation for brown coal.

ERNEST W. THIELE

Powdered-coal firing with special reference to brown coal and its low-temperature coke. PRADEL. *Feuerungstechnik* 13, 122-5(1925).—A review. E. W. THIELE

The distillation of lignites for the production of mineral oils and volatile matter. V. NEVEUX. *Genie civil* 87, 321-6 (1925).—A plant in Italy operating on lignite contg. 40% H_2O , 30% volatile matter and 30% residue has a capacity of 50 metric tons per day. Material is charged at the top of a shaft furnace and passes downward to a point of max. heat. Volatile hydrocarbons are not lost with H_2O because of the thickness of the upper layers and the passage of vapors into channels in sepg. walls which divide the mass in the lower part of the furnace. Yield is 36 kg. anhyd. tar and 20 kg. of oil per metric ton.

JACK J. HINMAN, JR.

Carbonization of Canadian fuels. II. Application of the principles of high- and lower-temperature carbonization to wood, peat and different classes of Canadian fuels. R. E. GILMORE. *Can. Chem. Met.* 10, 51-4(1926); cf. C. A. 20, 1314.—Reviews and discusses yields and heat balances of low-temp. carbonization, the compn. and properties of low-temp. coal tar, its com. utilization, etc.

W. B. PLUMMER

Method of determining the dew points of fuel-air mixtures. R. J. KENNEDY. *Bur. Standards, Sci. Papers* 500, 47-63(1925).—The theory of the method is based upon the assumption that the initial condensate in equil. with the remaining vapor is of essentially const. compn. for the range of pressures and temps. encountered in the engine manifold. The dew point is obtained from an equation expressed in terms of the pressure and mixt. ratio of the fuel-air mixt. and developed from the Clausius-Clapeyron equation and the ideal gas laws. The equation involves several consts., characteristic of the fuel which are detd. from measurements of the condensation temp. and the av. mol. wt. as computed from the const. ratio between the pressure and mass of the fuel. The app. used for the measurement of these properties consists of a thin-walled glass vessel of about 1500 cc. capacity, to which is sealed a metal cover provided with a manually operated fan having thin, blackened vanes, a buret graduated in cu. mm., and an outlet connected to a vacuum pump. The vessel is immersed in a water bath which is so fitted that a small area at the bottom of the vessel, which may be viewed through windows in the sides of the water bath, may be cooled locally to any desired degree. A measured quantity of fuel is vaporized in the vessel, which is then cooled, and the temp. of the bath when the last drop of liquid disappears from the cool spot as a result of raising the temp. at the rate of 1° in 3 or 4 min., is taken as the condensation temp. Check measurements do not vary by more than 0.5° . The pressure exerted by a known vol. of fuel is measured by connecting the vessel with a small, closed-end Hg manometer immersed in the bath, nearly evacuated and maintained at a const. temp. high enough completely to vaporize the max. charge employed. The app. is estd. to give results accurate to within about 2° . Measurements of the condensation temp. of alc. agree to within less than 1° with the figures computed from the Smithsonian Physical tables of vapor pressures.

B. C. A.

Determination of unsaturated, aromatic, naphthene and paraffin hydrocarbons, in motor fuels, and their automotive equivalents. GUSTAV EGLOFF and J. C. MORRELL. *Ind. Eng. Chem.* 18, 354-6(1926).—The motor fuel is distd. to 210° in a Hempel column,

the distillate treated with 80% (wt.) H_2SO_4 , washed, and redistd. to the same temp., the contraction with H_2SO_4 plus the residue from the 2nd distn. giving the % unsatd. hydrocarbons (resp. those reacted with H_2SO_4 and those polymerized). Aromatic hydrocarbons are detd. on the distillate from the 2nd distn. by nitration with 25/58/17 (parts by wt.) $\text{HNO}_3/\text{H}_2\text{SO}_4/\text{H}_2\text{O}$, this concn. being such that the nitro products do not dissolve in the acid but form a layer whose vol. may be read. Naphthenes are detd. by the aniline method in the residue from the nitration, and paraffins detd. by difference. Applied to synthetic mixts. the method gave good results. A no. of analyses of cracked and straight-run gasolines are given, and their automotive characteristics discussed.

W. B. PLUMMER

Experimental and theoretical study of anti-knock materials. WM. H. CHARCH, EDWARD MACK, JR. AND C. E. BOORD. *Ind. Eng. Chem.* **18**, 334-40(1926).—By the bouncing-pin app. of Midgley (cf. *C. A.* **18**, 1045, etc.), the anti-knock coeff. (as compared to PbEt_4) has been detd. for about 25 organo-metallic compds., of which most of the Pb compds. had coeffs. of over 60%, the Bi compds. were about 20%, all others being very weak in their action. About 30 other organo-metallic compds. examd. had no action. Expts. on the suppression of the sharp detonation of C_2H_2 in open tubes have shown a lack of parallelism with the action of anti-knock compds. in engine cylinders. A method of approx. detg. the *elec. cond.* of the cylinder gases during operation is shown, the deflection (current) varying from 14.7 during violent knocking down to 0.5-1.5 during smooth running, regardless of whether knocking is eliminated by an organo-metallic anti-knock agent or by changing the fuel (addn. of C_6H_6). A theory of the action of organo-metallic anti-knock agents is formulated based on their decomposition ahead of the flame front to produce "pyrophoric" metallic particles which propagate the combustion smoothly.

W. B. PLUMMER

Recovery of by-products in the gas industry. C. S. HEATH. *J. Western Soc. Eng.* **31**, Tech. Sect. 32-40(1926).—A semi-popularized discussion of tar, light oil etc., their recovery, and the products obtainable therefrom.

W. B. PLUMMER

Removal of organically combined sulfur from purified gas. G. OFFE. *Gas-u. Wasserfach* **68**, 493-4(1925).—Expts. to remove org. S compds. from coal gas by passage over heated Fe turnings are described. The gas contained about 30 g. of org. S per 100 cu. m., of which 95% was CS_2 . The S was reduced to between 1 and 2 g. per 100 cu. m. by passage over heated Fe turnings and then washing in NaOH. The temp. must not be too high. The products of the reaction of the gas with the Fe are C, S, Fe sulfide, H_2S and mercaptans. It is probable that the whole of the CS_2 is decomposed, and that the org. S compds. remaining are not attacked at the temp. used.

B. C. A.

A new instrument for the continuous indication of carbon monoxide in boiler flue gases. W. O. ANDREWS. *S. African Inst. Eng.* **22**, 145-53(1924); *J. Inst. Metals* **31**, 544-5.—It is shown that the amt. of heat undeveloped when even small quantities of CO are present in flue gases may be quite large. An app., invented and patented by A., by means of which the % of CO in boiler flue gases may be continuously indicated is described. A portion of the gas from the flue is aspirated through a soln. of potash then through a small elec. furnace, and finally through a special indicating soln. The potash removes all the CO_2 , the furnace then burns the CO to CO_2 and on the partial pressure of the CO_2 thus produced depends the acidity and thus the color of the indicating soln. The color varies from deep purple to yellow as the % of CO changes from 0 to 0.75.

H. G.

Mechanical grates and ash removers for producers. GWOSDZ. *Feuerungstechnik* **13**, 108-11, 157-60(1925).—A review of recent German patent literature.

Petroleum and tar hydrocarbons. F. BÖSSNER. *Z. Ver. Gas-u. Wasserfach* **66**, 13-7(1926).—A brief review and discussion.

W. B. PLUMMER

A peculiar form of corrosion in a tar still. R. STUMPER. *Feuerungstechnik* **14**, 7-8(1925).—The still was deeply corroded in peculiar grooves on the top, where condensation took place. The effect is probably due to HCl formed by the disassoc. of NH_4Cl known to be present in the tar.

ERNEST W. THIELF

The study and evaluation of coking coals. R. KATTWINKEL. *Gas u. Wasserfach* **69**, 145-50(1926).—A test has been developed in which 1 g. of coal and 10 g. of sand are mixed and coked in the standard ("Bochumer") coke test crucible, the compressive strength of the resultant button $\times 10 \times 1/A$ being taken as the coking index of the coal, where A is the non-cokable fraction of the coal. In the strength test the load is

uniformly applied by running shot into a container on top of the plunger of the app. The test differs from that of Meurice in the smaller amt. of sand used (M. uses 17 g. sand) and in the app. for the strength test. Detailed data are given comparing this to other methods, showing the effect of fineness of the coal sample, etc. A no. of the coals tested were from com. coking plants so that comparisons could be made on the basis of their known large-scale coking properties.

W. B. PLUMMER

Regulation of coke-oven gas exhausters. W. SCHWEDER. *Gas u. Wasserfach* 69, 168-9 (1926).—A brief discussion.

W. B. PLUMMER

Distribution of energy (STARKE) 13. Temperature and analysis of gases in the throat of a blast furnace (LENT) 9. Coal deposits of Albania (NOWACK) 8. S. pat. 1,573,824) 1.

Mitteilungen aus dem schlesischen Kohlenforschungsinstitut der Kaiser-Wilhelm-Gesellschaft in Breslau. Vol. 2. Ed. by Fritz Hofmann. Berlin: Gebrüder Borntraeger. 250 pp. M. 19 Pfg. 50.

Third Progress Report of the Sub-Committee on Benzol. Pub. by National Bureau of Casualty and Surety Underwriters. Reviewed in *Rubber Age* 18, 358 (1926).

Fuel. L. L. SUMMERS. U. S. 1,576,253, March 9. Raw coal is treated with hot phenol and C_6H_6 or other solvent for its sol. ingredients, and compressed, distd. solid carbonaceous residue is treated with the resulting soln.

Fuels for internal-combustion engines. T. MIDDLEY, JR. U. S. 1,575,436, March 2. A volatile Se compd. such as $Se(C_2H_5)_2$ is added to "low-compression" fuels such as kerosene and gasoline to increase the crit. compression of the fuel. U. S. 1,575,437 specifies the similar use of a volatile Te compd. such as $Te(C_2H_5)_2$. U. S. 1,575,438 specifies a volatile As compd., e. g., $As(C_2H_5)_3$. U. S. 1,575,439 specifies a volatile Sb compd. such as $Sb(C_2H_5)_3$. U. S. 1,575,440 specifies a volatile P compd., e. g., $P(C_2H_5)_3$. U. S. 1,575,441 specifies a volatile Cd compd., e. g., $Cd(CH_3)_2$. U. S. 1,575,442 specifies a volatile Bi compd., e. g., $Bi(C_2H_5)_3$. U. S. 1,575,443 specifies a volatile Ti compd., e. g., $TiCl_4$. U. S. 1,575,444 specifies a volatile Sn compd. such as $Sn(C_2H_5)_4$.

Burning fuel on a centrifugal grate. S. McLEWEN. U. S. 1,575,350, March 2. Coal or other fuel is retained in place by centrifugal force on a rotating grate during combustion.

Briquets. J. S. ROBESON. U. S. 1,576,248, March 9. A binder for making briquets of fuels, ores, etc., comprizes ingredients of waste sulfite liquor or the like, liquid residuum such as wood tar obtained in the destructive distn. of woody tissue, and molasses or similar thick residuum of sugar-bearing plant juices.

Pulverizing coal. H. KREISINGER. U. S. 1,576,335, March 9. In a pulverizing system including a mill and using air as a carrier, coal to be pulverized is preheated sufficiently that the sensible heat of the coal in pulverization is sufficient to dry it for transport in the presence of the carrying air.

Dehydrated lignite. E. P. SCHOCH. U. S. 1,574,174, Feb. 23. Lignite is heated in contact with mixed gas oil and fuel oil or other hydrocarbon oil to drive off moisture and effect impregnation of the lignite with oil. Unabsorbed oil is sepd. and a portion of the absorbed oil is removed by use of super-heated steam.

Enriching water gas. J. R. ROSE. U. S. 1,573,524, Feb. 16. Blue water gas is cooled and led through a mixing tower or chamber in which it is treated with liquefied hydrocarbon gas having a vapor tension of not less than 25 lbs. per sq. in. and not greater than 500 lbs. per sq. in. at atm. pressure and ordinary temp.

Ferric hydroxide, for gas purification, etc. WOODALL-DUCKAM (1920), LTD., E. W. SMITH AND T. C. FINLAYSON. Brit. 237,413, June 24, 1924. A solid mixt. of a sol. Fe salt and an alkali carbonate to the amt. of at least 1.5% is added to H_2O , the carbonate being in excess of combining proportion. The suspension may be oxidized with air and the $Fe(OH)_3$ is readily sepd. from liquids or solids when used in gas purification or the like.

Gas producer. C. W. LUMMIS and G. H. ISLEY. U. S. reissue 16,262, Feb. 16. (Original pat. No. 1,251,064; C. A. 12, 529.)

Fuel feed for gas producers. R. DAAE. U. S. 1,573,811, Feb. 23.

Ascension pipes for gas retorts, etc. ALDRIDGE & RANKEN, LTD. AND T. A. BEAVAN. Brit. 237,111, Aug. 13, 1924.

Apparatus for regulating the flow of gas to different gas-consuming appliances. J. P. FISHER. U. S. 1,575,260, March 2.

Cracking tar oils. CHEMISCHE FABRIKEN VORM. WEILER-TER MEER. Brit. 237,415, June 26, 1924. Gases rich in C_2H_4 are obtained by destructive distn. of tar oils b. 250° or higher in the presence of steam at $800-900^\circ$.

Distilling tars and oils. E. BLÜMNER. U. S. 1,573,370, Feb. 16. Tar or oil is delivered to the lower portion of a column of hot liquid metal such as molten Pb and upward flow through the metal is retarded by baffles, Raschig rings or like devices while the tar or oil is maintained in finely divided condition. A downward return flow of the metal (some of which rises with the tar or oil) is effected out of contact with the rising tar or oil.

Controlling combustion of carbonaceous materials. I. H. DERBY and C. B. EDWARDS. U. S. 1,576,179, March 9. Coal-tar coke or similar carbonized material is prep. contg. Pb oxide in order to improve its burning properties.

Ovens for coking and destructive distillations. J. A. LENCAUCHEZ. Brit. 237,369, May 5, 1924. Heated gas such as distn. or water gas is passed through openings in the floor on which the material undergoing distn. rests.

Coke oven with vertical flues. MASCHINEN-BAU-AKT.-GES. ELSAS. Brit. 237,282, July 18, 1924.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Chlorine in the petroleum industry. LOUIS BURGESS. *Trans. Am. Electrochem. Soc.* 49 (preprint) (1926).—Cl is used to sweeten distillates, and reacts according to the equation:
$$\begin{array}{c} R-SH \\ R-SH \end{array} + \begin{array}{c} Cl \\ Na \end{array} = \begin{array}{c} RS \\ RS \end{array} + H_2O + NaCl. AlCl_3 \text{ forms addn. compds. with petroleum which on heating yield simpler hydrocarbons. This reaction is being used for the production of } gasoline. Cl \text{ is also used in the manuf. of ethylene glycol, a substitute for glycerol as an anti-freeze; in the production of methyl and methylene chlorides; and in the manuf. of aliphatic alcs. and their Cl derivs. H. S.}$$

Protecting "doctor" [in petroleum refining] from carbon dioxide pollution. L. J. CATLIN. *Ind. Eng. Chem.* 18, 319 (1926). E. J. C.

Oxidation of petroleum oils. G. S. PETROV AND A. I. DANILOVICH. *Trans. Karpov Inst. Chem.* (Russian) 1925, No. 4, 143-56.—Hydrocarbon oils were partially oxidized to fatty acids by refining distd. oil of Caucasian origin with fuming H_2SO_4 and submitting the product obtained to a prolonged current of air at 140° . After 40 hrs. the reddish yellow oil obtained possessed the following consts.: acid no. 22.14, sapon. no. 61.58, Br no. 8.59, I no. 11.09. The yield in acids was 5.20% on the amt. of oil taken for oxidation. The acids after being purified had the following consts.: sapon. coeff. 219.0, acid no. 118.0, I no. 14.4, acids sol. in C_6H_6 60.1, acids and resin insol. in C_6H_6 39.1. Hydrocarbon oils have also been oxidized by being heated in a current of moist air in presence of Co naphthenate; the yield in acids was 8.7% at best. The acids when freed from the mineral oil give soaps, about equal in detergent effect to those obtained from sunflower oil. The presence of hydroxy acids insol. in C_6H_6 is harmful to the quality of the soap obtained. BERNARD NELSON.

Proposed method of test for neutralization number of petroleum oil, titration by electrometric method. MAX HECHT. *Proc. Am. Soc. Testing Materials* 25, Pt. 1, 282-5 (1925); cf. C. A. 19, 1940.—A detailed description is given of a revised and simplified app. and method. The outstanding features of the revised set-up are: use of bright Pt electrodes and discontinuance of Hg contacts, simple form of "bridge" consisting of agar-agar and KI, use of alc. KOH instead of $EtONa$, means of equalizing the potential of the Pt electrodes. A. PAPINEAU-COUTURE.

Report of sub-committee XXI on crude petroleum. N. A. C. SMITH. *Proc. Am. Soc. Testing Materials* 25, Pt. 1, 290-1 (1925).—Collaborative tests on Montebello crude, Mexia crude, and Mid-Continent crude showed satisfactory checks for the percentages reported of naphtha in the crudes; but the agreement in the percentages reported as distg. at 105° and at 140° is not very satisfactory. The conditions of distn. (rate of distn. and temp. of condenser H_2O) are being further investigated. A. PAPINEAU-COUTURE.

Investigations on the action of ozone upon petroleum. I. Action of ozone on the

saturated hydrocarbons of petroleum. GEN-ITSU KITA, RYONOSUKE ABE AND SIGERU TADA. *J. Soc. Chem. Ind. Japan* 29, 7-12(1926).—Ozonized O_2 contg. about 5% O_3 was passed into a fraction (50 cc.) of Kurokawa petroleum (b. 150-300°, iodine value 5.66, acid value 0.36, d_{25}^{25} 0.8405, n_D^{25} 1.4578 and α_D^{25} 0.21) and into liquid paraffin (Japan. Pharm IV) at 0° for a definite time. The resulting ozonized oil was boiled with 200 cc. H_2O for 4 hrs. under reflux and its properties were examd. after drying. In the satd. hydrocarbons, iodine and acid values, sp. gr., refractive index and viscosity increased according to the increase of the time of the treatment, while rotatory power decreased. In the liquid paraffin, acid value, sp. gr. and viscosity were increased slightly by the treatment, while rotatory power decreased and iodine value and refractive index were not influenced.

K. K.

Determination of viscosity of oils. M. V. BORODULIN. *Trans. R. Inst. Applied Chem. (Russian)* 1925, No. 4, 17-26; cf. *C. A.* 19, 1624.—A simplified method for detn. of viscosity of oils without the use of a viscometer has been contrived. It is based on the circumstance that the speed of the fall of a drop of water through a layer of a given oil is characteristic of the degree of viscosity of that oil. A test tube with inside diam. 3-3½ cm. is filled with oil to be tested to the height of 10 cm. and immersed to about the same height in a beaker of water. A thermometer placed in the bath and another one in the oil are used as stirrers for the purpose of maintaining a uniform temp. throughout the oil. The water bath rests on a wire gauze over a Bunsen burner or any other source of heat. Three cm. directly above the surface of the oil is the lower end of a glass tube the upper end of which is connected by means of a rubber tube with a buret or a funnel contg. water. A pinchcock which compresses the rubber connection permits delivery of drops of the desired size. When the oil reaches the desired temp. a drop of water is made to fall from the glass tube, and the number of seconds required for it to traverse the layer of oil from the top to the bottom is noted. If the glass tube used is of such a diam. as to deliver drops of the size $1/32$ - $1/35$ cc., then the number of seconds required for the drop to traverse the oil corresponds to the figure expressing the degree of viscosity obtained by the use of Engler's viscometer. The quantity of oil required for a test is considerably less than with a viscometer, and the detns. take much less time. Various improvements of the app. are suggested, all based on the same principle. The figures obtained on running various oils at different temps. are given and their comparison with the figures obtained by using Engler's viscometer.

BERNARD NELSON

The probable future of the utilization of oil shale. R. A. BAXTER. *Wisconsin Engineer* 30, No. 5, 154, 155, 157, 172, 174(1926).—The fuel aspect of oil shale utilization is considered on the basis of a history of the developments in the use of solid and liquid fuels. Comparison is made of oil shales, lignites, and other low-grade fuels of the quality of the oils produced and the nature of the solid residue. The conclusion is drawn that an American oil shale industry will be operating on a commercial scale within the next 8 yrs.

ROBERT A. BAXTER

Life test for transformer oils. E. A. SNYDER AND D. C. COX. *Proc. Am. Soc. Testing Materials* 25, Pt. I, 363-8(1925); cf. *C. A.* 18, 1193.—A revision of previous descriptions of the app. and procedure, including improvements made in the construction of the app. as a result of further experience in several labs.

A. P.-C.

Mineral oils for transformers and circuit-breakers. H. STÄGER. *Schweiz. elektrotech. Verein, Bull.* 16, 188-214(1925); *Science Abstracts* 28B, 426-7; cf. *C. A.* 20, 816.—The general requirements laid down by the draft specification of the Swiss Electrotech. Assoc. are: The oil should appear clear and free from solid particles visible to the naked eye at atm. temp. and also at 110°. The viscosity, as detd. by the Engler method, should not exceed 8 at 20°. The time required for the oil to flow 10 cm. in an inverted tube 15 mm. in diam. under prescribed conditions at -20° should not exceed 10 sec. The flash-point, as detd. by the Marcusson method, should be at least 145°. The oil must withstand, without any discharge, 30,000 r. m. s. volts between spherical electrodes 12.5 mm. diam., 5 mm. apart. The oil should contain neither mineral acids nor bases; a permissible index of acidity is defined in respect of org. acids and in respect of oil tested after removal from app. in service. A sample of oil contg. 2 lengths of cotton is heated to 115° for 336 hrs. (2 weeks); at the end of the first week 1 of the pieces of cotton should not be weakened by more than 20%, and at the end of the fortnight the strength of the other piece should not have decreased by more than 30% total. Stipulations are also made concerning the sludging and acidity of the oil during this test. The procedure to be followed during the various tests is explained in detail, and the app. required is illustrated.

H. G.

Report of sectional committee on penetration (test of asphalt). I. M. LAW. *Proc.*

Am. Soc. Testing Materials 25, Pt. I, 301-6(1925).—Comparative tests with different needles showed that an angle tolerance of $\pm 30'$ can safely be allowed without any practical deviation from results by the present standard needle. A. P.-C.

Petroleum and tar hydrocarbons (BÖSSNER) 21. Effect of rock flowage on the kerogen of oil shale (VAN TUYL, BLACKBURN) 8. Distillation of cellulose, wood, etc., under H pressure (FIERZ-DAVID, HANNIG) 23. Apparatus for distilling shale or wood (U. S. pat. 1,573,824) 1. Distilling oils (U. S. pat. 1,573,370) 21. Heating petroleum (U. S. pat. 1,573,591) 13.

Cracking hydrocarbon oils under pressure. J. E. BELL. U. S. 1,575,031, March 2. Vapors produced by cracking oil under pressure are subjected to a regulated condensation while under pressure, uncondensed vapors are permitted to escape through a fixed orifice, and increase and decrease in the condensation are effected with increase and decrease of pressure.

Decomposing hydrocarbon oils. C. M. ALEXANDER. U. S. 1,573,532, Feb. 16. Crude petroleum or other relatively light oil in atomized liquid form is injected below the surface of a bath of heated heavier oil, *e. g.*, a residuum oil, at such a depth that the lighter oil will be cracked before vaporization. After sepn. of the cracked oil and C, the heavy oil is reused in the process.

Blending and purifying hydrocarbons. G. EGLOFF. U. S. 1,575,905, March 9. Light gasoline-like hydrocarbons such as those contained in casinghead gasoline are blended with a heavier absorbing oil and the mixt. is treated with a purifying compound formed with NaOH and PbO.

Emulsifying, hydrogenating or cracking hydrocarbons or other liquids. J. E. NYROP. Brit. 237,325, April 3, 1924. Material under treatment, *e. g.*, oil and an emulsifying soln., or $C_{10}H_8$ and H for hydrogenation, or petroleum oil, is fed between adjacent rotating plates between which (except at their central portion) a packing is placed, *e. g.*, wire netting, glass wool or nickellized pumice.

Distilling mineral oil. L. GRANGER, C. MARILLER and C. PRACHE. U. S. 1,574,622, Feb. 23. Vapors from oil distn. are condensed in evaporators with rapid circulation of H_2O to insure operation with small temp. drop and production of steam at a temp. only slightly less than the condensed vapors and at a high pressure. This steam is used for heating the oil and for the production of power.

Distillation of mineral oils. J. E. BELL. U. S. 1,576,401, March 9. Oil flows through a series of stills maintained at successively higher vaporizing temp. Part of the vapors given off in each still is condensed by absorbing heat from them in oil of lower temp. and the oil, between successive stills, is heated by the condensed vapors from stills later in the series.

Breaking emulsions. L. G. GATES. U. S. 1,573,389, Feb. 16. Emulsions such as crude petroleum contg. H_2O are brought into intimate contact with grounded filter-press cloths or other medium which is a conductor of static electricity and adapted to bring both phases of the emulsion to the same elec. charge.

Refining and deodorizing bitumens. G. W. ACHÉSON. U. S. 1,574,742, March 2. Crude oil or similar "bitumen" is treated with a solid reflocculated adsorbent material such as reflocculated clay and with concd. H_2SO_4 or other acid reagent, the refined bitumen is sepd. from the acid sludge, and is further treated with an anhyd. oxide such as MgO to effect decolorization.

Apparatus for cooling and condensing hydrocarbon vapors. E. W. ISOM and J. E. BELL. U. S. 1,575,269, March 2.

Coking gilsonite. C. N. FORREST. U. S. 1,573,764, Feb. 16. Gilsonite is heated and coked within such temp. limits (usually about 450° as a max.) as to retain N in the coke unfixed, and the coke is treated in a gas producer to release the N as NH_3 . U. S. 1,573,765 describes an oily product produced by the distn. of gilsonite; it contains a relatively large proportion of N and unsatd. hydrocarbons and yields an oil of terpene odor on redistn. and H_2SO_4 treatment.

Treating natural gas gasoline. G. G. OBERFELL, A. M. BALLARD, R. C. ALDEN, F. L. UTSINGER and W. R. LENTZ. U. S. 1,574,507, Feb. 23. Free S is dissolved in natural gas gasoline and the gasoline contg. the added S is then passed through a soln. of NaOH contg. PbO.

Motor fuels containing tetraethyl lead, etc. T. MIDGLEY, JR. U. S. 1,573,846, Feb. 23. In order to increase the crit. compression of gasoline or similar fuels they are admixed with small proportions of $PbEt_4$ or similar alkyl metal compd.

Mud-laden fluid for sealing or controlling oil or gas wells. B. K. STROUD. U. S. 1,575,944, March 9. A suspension of Fe oxide is used. U. S. 1,575,945 specifies the use of a mud contg. barytes or other slimy compn. with a sp. gr. materially in excess of that of a clay suspension of the same viscosity.

Pressure still for oil refining. D. PYZEL. U. S. 1,574,935, March 2.

Tubular oil-cracking still. J. F. BELL. U. S. 1,574,546, Feb. 23. U. S. 1,574,547 specifies recirculating a portion of hot waste heating gases, together with fresh combustion gases, over the oil-heating elements of the still.

Still for oil ("coke still"). G. H. HURSHMAN. U. S. 1,575,919, March 9.

Apparatus for separating oils from water, etc. G. L. FOGLER. U. S. 1,576,108, March 9.

Apparatus for cracking hydrocarbon oils and for treating the product with hydrogen. F. C. VANDE WATER and F. R. SUNDERMAN. U. S. 1,575,663, March 9.

Apparatus for making oil-gas. C. MATTHEWS, JR. and W. C. MATTHEWS. U. S. 1,574,502, Feb. 23.

Lubricant. I. M. CUSTER. U. S. 1,574,642, Feb. 23. A mixt. comprising deflocculated graphite and coal tar oil is used on springs, nuts, tire rims, etc. Lard, "red engine oil" and kerosene also may be used in the mixt.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Cellulose: Its chemistry with particular reference to the manufacture of rayon. G. J. ESSELEN, JR. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 98-100; *Am. Dyestuff Rept.* 15, 166-8.—An address. L. W. RIGGS

Polysaccharides. XXXIV. Contribution to the knowledge of hydro- and oxycellulose. P. KARRER and TH. LIESER. *Cellulosechemie* 7, 1-6(1926); cf. C. A. 20, 1416.—Hydrocelluloses vary in properties according to the method of prepn. A hydrocellulose completely sol. in 10% NaOH can be produced with a reducing power approaching that of many natural celluloses. It is obtained by treatment of cotton with 84% H_3PO_4 at room temp., followed by warming to 35° for some time. On diln. of the resulting soln. with H_2O the hydrocellulose ppts. This product can be methylated in alk. soln. at low temp. to give a substance contg. 42-43% MeO. The MeO content compares favorably with that of cotton or lichen after methylation. The methylated hydrocellulose is completely sol. in H_2O . Acetylation, as with lichens, must be carried on at higher temp. than with cotton, but hydrocellulose yields cellulose octaacetate in about the same quantities as cotton. The alk. soly. of hydrocellulose is not due to the presence of COOH groups, as its acidity is very low, but probably to peptization or the formation of a NaOH complex. Hydrocellulose, if properly made, can be distinguished from oxycellulose by its low acidity. When prepd. as above described it forms no isosaccharin on heating with $Ca(OH)_2$ soln., being like cotton and unlike oxycellulose in this respect. A study of the xanthogenates of cellulose and lichen showed them to be very similar in properties. The compn. of rapidly dialyzed solns. of each was the same, for in each case 2 $C_6H_{10}O_6$ complexes required 2 S atoms and 2 Na atoms. Their Me esters are alike and their heavy metal salts give the same color reactions. Mention is made of the work of E. Ott, not yet published, which shows the Röntgen diagrams of lichens, pptd. hydrocellulose, H_3PO_4 -hydrocellulose, and oxycellulose to be the same, suggesting their chem. identity. W. H. SWANSON

The distillation of cellulose, wood and similar substances under hydrogen pressure with catalysts. H. E. PIERZ-DAVID and MAX HANNIG. *Helvetica Chim. Acta* 8, 900-23(1925).—The dry distn. of cellulose, wood, starch or lignin is apparently uninfluenced by hydrogen, in the absence of catalysts, even when distd. under H pressure up to 300 atm. In the presence of NiO, however, which is reduced by the H to finely divided Ni, these substances are converted almost quant. into liquid or gaseous compds. Cu has much less effect and Fe practically none, as the reduction of the FeO does not take place until after the decompn. of the principal compds. by the distn. processes. Investigations of gas coals, using the Bergius process, gave negative results. The principal products obtained by dry distn. of the above materials under H pressure are: H_2O , aromatic phenols, volatile org. acids (formic to valeric acid), numerous diketones, a few monoketones, numerous alcs. (including MeOH, whose existence as a cellulose distn. product has previously been disputed), a cyclic glycol, many homologous furans and gas (mainly CO and CO_2). LOUIS C. FLECK

The "copper number" as an exponent of the quality of cellulose. M. L. GRIFFIN. *Paper Trade J.* 82, No. 8, 150-1 (1926); *Paper Mill* 49, 186, 188 (1926).—From a brief discussion of the nature and properties of cellulose, G. concludes that "the cellulose complex in its widest sense may be defined as comprizing all the polysaccharide carbohydrates which form an essential portion of the structure of the plant and which yield cupric reducing sugars on hydrolysis by acids," and that "cellulose may be defined to be the resultant residue from a series of carefully regulated processes of attrition by methods of selective extn., oxidation and hydrolysis, sufficient to effect the complete removal, in the mildest possible manner, of the other constitutional complexes, together with all adventitious and extractive matter." The detn. of the Cu no. is considered to be the most definite measure for diagnosing the chem. condition of cellulose in numerical terms, yet available. G. describes and recommends Brady's method (*C. A.* 15, 2360).

A. PAPINEAU-COUTURE

Evaluation of sulfite pulp. TH. BENTZEN. *Paper Trade J.* 82, No. 8, 197-203 (1926); *Paper Mill* 49, No. 9, 116-24 (1926); *Paper Ind.* 7, 2003-9 (1926).—The technic of the detn. of α -, β - and γ -cellulose is minutely described. The residue obtained in the α -cellulose detn. is shown to be unaffected by a second mercerizing treatment, but degraded slightly by heating 2 hrs. at 40° with water, and degraded considerably with almost complete destruction of fibrous structure by heating 6 hrs. at 70° with water contg. a trace of bleaching powder and then drying. It is suggested that the difference in durability of rag and sulfite papers may be due to the difference in their α -cellulose contents.

A. PAPINEAU-COUTURE

Native fibers not now used which might be used in the paper industry. G. SRI-LERGEREN. *Svensk Pappers-Tid.* 28, 613 (1925).—On the basis of 0.5 mm. min. to 35 mm. max. fiber length and a min. strength of 10-12 kg./mm.² the following hitherto unused fibers might be used: Class I, min. strength 20 kg./mm.², nettle, hops, bean stems and greenwood; Class II, min. strength 15 kg./mm.², reeds, timothy grass, canary reed, manna grass, cock's food grass, feather grass and pine needle fibers; Class III, min. strength 8-10 kg./mm.², beach grass, rushes and spruce and juniper fibers.

W. SEGERBLÖM

Report on the chemical examination of fiber from the bark of terap, tutor and baru. R. O. BISHOP. *Malayan Agr. J.* 13, 382-6 (1925).—Analysis of two samples each of the barks of terap (*Artocarpus kunsi* (King), tutor (*Hibiscus macrophyllus*, Roxb.) and baru (*Hibiscus floccosus*, Mast.) gave the following av. results on the dry basis (except H₂O which is on the wet basis): H₂O 11.75, 13.26, 12.72; ash 6.91, 6.91, 4.35 acid-purification loss 9.22, 6.48, 6.95; hydrolysis—"A" loss 22.53, 13.33, 15.92; hydrolysis—"B" loss 31.11, 25.61, 24.89; cellulose content 64.1, 62.6, 66.3%; fiber length 9-27 (av. 18.0), 1.8-4.5 (av. 3.3), 2.5-3.6 (av. 3.2); av. fiber diam. 0.0333, 0.0257, 0.0257 mm. Tutor and baru gave a yellow-gray color with I and H₂SO₄ in glycerol, and a transient violet followed by a deep blue color with I and ZnCl₂; terap is colored yellow by I and H₂SO₄ in glycerol, and wine-red changing to deep blue with I and ZnCl₂. The bark was pulped by digesting with water to a steam pressure of 65 lb. for 60 min., draining, washing with cold water, digested 6 hrs. with 20% NaOH (at a concn. of 2.5%) at a pressure of 65 lb., washing and beating for 3 hrs. Small bleaching tests showed good color with reference to the consumption of Cl, and it should be possible to produce a satisfactorily bleached paper from one of the three barks. Tutor and baru barks are shown to be almost identical in chem. and microscopic characteristics and appear suitable for making a paper of good quality. Terap bark, though chemically similar to that of tutor and baru, has a much longer ultimate fiber, comparable with that of hemp; and it appears that the terap bast fiber after suitable treatment might be utilized for some of the same purposes as hemp.

A. PAPINEAU-COUTURE

Contribution to the knowledge of lignin from spruce wood. P. KLASON. *Svensk Pappers-Tid.* 28, 609-10 (1925).—K. takes exception to some of the findings of Dorcé and Hall (cf. *C. A.* 19, 2742) and corroborates the work of Tilghman regarding the action of H₂SO₄ on vegetable fibers.

W. SEGERBLÖM

Chemical control in the manufacture of paper. E. HOLTAN. *Papir-Journalen* 14, 5, 17 (1926).—A lecture. The control has become more and more dependent upon chem. analytical figures. These figures are most useful if recorded graphically and as a function of time.

E. O. ELLINGSON

Chemistry of the sulfite process. IX. Influence of hydrogen-ion concentration. R. N. MÖLLER, W. H. SWANSON AND RAGNAR SÖDERQUIST. *Paper Trade J.* 82, No. 9, 58-61 (1926); cf. *C. A.* 19, 2743.—Results of a large no. of exptl. cooks, details of which are given and discussed, lead to the following conclusions: (1) The view of the sulfite pulping process as an acid hydrolysis of wood is confirmed as far as concerns the removal

of carbohydrate material. (2) The removal of lignin is the result of the sp. action of ionized H_2SO_4 . (3) The simultaneous removal of carbohydrate material and lignin are not mutually dependent, and the results obtained with H_2SO_4 and bisulfites depend upon the, at least, dual reactive capacity of the H_2SO_4 . (4) The removal of lignin by H_2SO_4 and bisulfites is hindered by preliminary action of acid reagents, to an extent dependent on the severity of the acid treatment. X. **Easy-bleaching pulp.** W. H. SWANSON AND W. H. MONSSON. *Ibid* 62-4—Expts. described show that in the cooking of spruce for easy-bleaching sulfite the temp. rise to any given max. should be carried on at a rate sufficiently slow to insure max. removal of the lignin at the lowest possible temp. consistent with the time available for the cooking. Bringing the temp. up through the cooking range, above 110° , too rapidly, to compensate for a shorter cooking time, reduces the yield and strength of the pulp. A slower rate of temp. rise, although a longer time for completion of the cook is required, increases the yield and improves the quality of the pulp. Lowering the max. temp. at which the cook is completed lengthens the time required but again increases the yield and improves the quality of the pulp. The reduction of pressure during the later stages of the cook, for recovering SO_2 , serves to increase the yield of desirable pulp slightly, provided the pulp has reached a high degree of purification before the pressure is reduced. Pressure reduction at too early a point slows up the rate of cooking and produces a raw pulp. To effect purification under such treatment requires long cooking or cooking at high temps. and decreases the yield by hydrolysis of the cellulose. Correctly cooked pulps do not suffer loss of strength when properly bleached. Overbleaching is detrimental to strength, particularly with pulp cooked with too rapid a temp. rise. The chem. loss in wt. of pulp on bleaching depends on the bleachability alone; the harder the pulp bleaches the greater will be the loss.

A. PAPINEAU-COUTURE

Kraft pulp and kraft paper. O. HEIJNE. *Svensk Pappers-Tid.* 29, 32-5(1926).—Descriptive.

W. SEGERBLUM

Power and fuel requirements in the paper-pulp industry. A. HARLIN. *Svensk Pappers-Tid.* 29, 9-13(1926).—Cellulose plants used (1924) 500 kg. coal per ton sulfite and 800 kg. per ton sulfate pulp, based on dry unbleached pulp. These figures are higher than Sundblad's ideal figures for 1922. Sulfite alc. required 2.7 kg. coal per kg. 100% alc. The power required for dry unbleached pulp was 300 kw. hrs. per ton of sulfite and 340 for sulfate pulp. Wet pulp required 650 kw. hrs. per ton. W. S.

Fuel requirements of the sulfate pulp industry. G. SUNDBLAD AND A. HARLIN. *Svensk Pappers-Tid.* 29, 61-2(1926).—S. contends that the data by H. (see preceding abstract) were based on 5 old-fashioned sulfate plants in a single district. H. presents new and more complete data to show that his former figures hold for the 26 sulfate plants in Sweden.

W. SEGERBLUM

Apparatus and method for experimental investigations of the production of soda pulp. D. E. CABLE, R. H. MCKEE AND R. H. SIMMONS. *Paper Trade J.* 82, No. 8, 158-61(1926); *Paper Mill* 49, No. 9, 138-44(1926).—A detailed description of a small exptl. chipper by means of which chips of uniform length can be produced, and of a small exptl. gas-heated, rotary soda pulp digester, and also of the technic of the yield tests carried out with this digester.

A. PAPINEAU-COUTURE

A modern soda pulp mill. R. P. WOOD. *Paper Trade J.* 82, No. 8, 147-50(1926); *Paper Mill* 49, No. 9, 162, 164(1926).—Detailed description of the pulp mill of the Tona-wanda Paper Co., at North Tonawanda, N. Y.

A. PAPINEAU-COUTURE

The variation in alkalinity during the cooking of soda and sulfate pulps. C. KULLGREN. *Teknisk Tids.* 22, 174(1925); *Tech.-Wiss. Teil, Papierfabr.* 24, 20-3(1926).—The usual methods of detg. the alkali in black liquor give results of doubtful value owing to the hydrolysis of Na_2S . The Koelichen method (*Z. physik. Chem.* 33, 129 (1900)) is based on the fact that diacetone alc. decomposes to Me_2CO with a velocity proportional to the OH-ion content of the soln. and is recommended for evaluating the alkali in black liquor. Cooking tests on fir wood, by both the soda and the sulfate processes, showed that, although the alky. in normality was approx. the same initially in both liquors, there was a more rapid decrease in the alky. of the sulfate liquor up to 150° . During the latter part of the cooking period, at which the max. temp. prevailed, the sulfate liquor was less alk. than the soda liquor. Cellulose is attacked much less by the sulfate liquor and the pulp yield is higher. The alky. of the soda liquor was about $\frac{1}{2}$ of the initial amt., while that of the sulfate soln. was much less. The role of Na_2S in the manuf. of pulp and the rapid diminution of the alkali content are discussed. NaHS , the hydrolysis product of Na_2S , does not exert a solvent action on the wood but reacts with it to form S compds., which are easily sol. in NaOH . The alky. of the cooking liquor is thereby reduced.

J. L. PARSONS

Needle paper. H. POSTL. Tech.-Wiss. Teil, *Papierfabr.* 24, 23(1926).—Paper suitable for packing needles should be manufd. from clean hemp or linen rags which have been boiled with CaO, thoroughly washed and then beaten. S compds. and an excess of acid in the sizing process should be avoided. After the paper is cooled to room temp., it is moistened and 10–12 hrs. later is passed through 8–10 cold calender rolls.

J. L. PARSONS

Recent developments in the manufacture of pulp and paper in America. WALTER BRECHT. *Wochbl. Papierfabr.* 57, 122–4(1926).—Mfg. conditions in the United States and raw materials for paper-making are discussed.

J. L. PARSONS

The size of the particles in wood pulp. D. KRUEGER. Tech.-Wiss. Teil, *Papierfabr.* 23, 767–8(1925).—The size and arrangement of the crystallites in cellulose depend on the natural conditions of the plant growth and on the treatment of the raw material in industrial processes. From the ease of soly. of cellulose esters and the viscosities of their solns., it is inferred that wood pulp is composed of smaller particles than cotton cellulose. The results of diffusion expts. of carefully nitrated cellulosic material showed that the size of the particles in sulfate pulp is 1.4×10^{-6} cm.; in sulfite pulp, $2.2\text{--}2.4 \times 10^{-6}$ cm.; and in cotton, 3.4×10^{-6} cm. The larger particles of cotton account for the differences in properties of its esters, such as a lesser soly. and greater viscosity. In the ripening of alkali cellulose for viscose, the increase in reactivity is traceable to a diminution of the particle size from 2.4 to 1.4×10^{-6} cm. A suitable test for evaluating the particle size and the ripening of viscose would consist in ascertaining the viscosity of the nitrate soln., prepd. under standard conditions. The diam. of α -cellulose particles is about 1×10^{-6} cm. The usual bleaching process for sulfite pulp reduces the size of the crystallite to $\frac{2}{3}$ the original. When hemp pulp was beaten for 4 hrs. in a beater, the size of the particle was reduced one-half.

J. L. PARSONS

The effect of chemicals on the paper-making properties of pulps. RUDOLF SIEBER. Tech.-Wiss. Teil, *Papierfabr.* 23, 765–7(1925).—The effect of acids, alkalies and alk earth hydroxides on the strength and beating properties of pulps is described. Treatment of a sulfate pulp with 1% H_2SO_4 soln. for 3 hrs. at 50° resulted in a diminution of the paper strength to 13% of the original untreated pulp, but the beating properties, detd. by the Lampen ball mill, were not affected. Lactic acid produced no change when allowed to act in a 2% soln. on sulfite pulp for 48 hrs. at 30° , and this in general was true of org. acids. Comparatively strong cold alk. solns. also have no effect. Treatment of sulfite pulp with $\text{Ca}(\text{OH})_2$ or $\text{Ba}(\text{OH})_2$ at 100° for 2 hrs. altered the strength and beating properties adversely, but the former was partially restored by using 0.1 N H_2SO_4 . When pulp was immersed in a 10% Na_2SO_4 soln., a poorly beaten stock, with inferior strength, was obtained. A similar result was noted when sulfate pulp was beaten and tested after being dried for 14 days.

J. L. PARSONS

Alkali determination in black liquors from sulfate pulp manufacture. A. MATZNER. *Wochbl. Papierfabr.* 56, 1556(1925).—Treat 20 cc. black liquor with sufficient neutral NaCl to form a thick sirup. Add small amts. of distd. water and NaCl with shaking until the vol. becomes about 250 cc. An excess of NaCl should always be present. Heat to boiling, filter, wash with hot satd. NaCl soln., and dil. to 500 cc. Titrate an aliquot portion of the soln. with standard acid.

J. L. PARSONS

Use of the chlorine gas process in the paper industry: its present applications and future possibilities. GIULIO CONSIGLIO. *Papier* 28, 1291–1300(1925).—The mill of the Elettrochimica Pomilio, Naples, for the treatment of esparto uses 160–80 kg. NaO, 400 kg. Cl gas and 20 kg. of Cl as NaOCl, per ton of bleached pulp. The pulp contains 80–81% cellulose, 1.0–1.5% ash and has a Cu no. of about 2.4. The spent alk. liquor can be used for the prepn. of a synthetic tan, for the prepn. of an insecticide which can be used instead of HCN for the destruction of certain fruit tree parasites, and for the prepn. of a binder for fuel briquets. The process is very flexible and allows of wide variations in the relative proportions of NaOH and Cl. In the treatment of wheat and rice straws and of esparto on a com. scale, the consumption of raw materials varied from 11.2 to 33.6% NaOH and 83.9 to 18.0% Cl. Yields obtained under various conditions of treatment were: wheat straw 38.5–42.0%, rice straw 31.7–38.9%, esparto 38.5–42.0%. Tests have shown the possibility of economically treating bagasse by the Cl gas treatment, and the possibility of modifying the process by elimination of the preliminary alk. impregnation for the production of pulp suitable for the manu. of news print at a cost lower than that of groundwood.

A. PAPINEAU-COUTURE

Manufacture of pulp with the aid of chlorine. WILLI SCHACHT. Tech.-Wiss. Teil, *Papierfabr.* 23, 759–62(1925).—Polemic with U. Pomilio (C. A. 20, 287). The manuf. of pulp with the aid of gaseous Cl leads to the production of HCl and HOCl in varying amts., as well as to the chlorination of the lignin. The acids attack the fibers

deleteriously. The De-Vains process, consisting of treating the fibrous material with alkali followed by Cl water, tends to remove the hemicellulose constituents, thereby decreasing the pulp yield. The S process removes most of the lignin with Cl salts and Cl water is subsequently added. Less HCl is produced by this process, and less chemicals and labor are required. Esparto pulp manufd. by this method yielded a paper possessing a density and thickness closely approaching those of a paper made from soda esparto pulp.

Alkali loss in sulfate pulp manufacture. RUDOLF SIEBER. *Tech.-Wiss. Teil, Papierfabr.* **24**, 6-7(1926).—The total alkali loss in sulfate pulp manuf. is 5-10 kg. per ton of pulp. The distribution of these losses is given. J. L. PARSONS

The application of hydrogen-ion control to the manufacture of pulp and paper. W. A. TAYLOR. *Paper Trade J.* **82**, No. 8, 166-77(1926); *Paper Mill* **49**, No. 9, 170-81(1926); *Paper Ind.* **7**, 1983-93(1926).—An explanation of the meaning of H-ion concn and p_H values, with a description of the colorimetric method of p_H detn. and a discussion of its importance in the various operations in the paper industry: bleaching, beating, engine and tub sizing, coloring, coating and water purification. A. P.-C.

Increasing the suspension of the coating mixture by the addition of colloids. B. K. STEADMAN. *Paper Trade J.* **82**, No. 8, 209(1926); *Paper Mill* **49**, No. 9, 166(1926).—Use of protective colloids is suggested for preventing settling out of clay from coating mixts. which are allowed to stand some time before use. Addn. of tannic acid caused flocculation of the mixt. Addn. of 5% of gum arabic improved the suspension, but thickened the soln. with increase in viscosity; the coating mixt. did not spread evenly and there were numerous pin holes in the surface of the coating. Addn. of 3% of S-brand silicate of soda had similar results to the gum arabic, thickening the mixt. even more, but resulting in fewer pin holes. A. PAPINEAU-COUTURE

Glue-bound coated paper. G. K. HAMILL. *Paper Trade J.* **82**, No. 8, 247-51(1926).—The investigation on glue-clay coating mixts. previously reported upon by Gottschalk (*C. A.* **19**, 175) was extended to include satin white and blanc fixe, and the following additional conclusions are drawn: the use of glue introduces no new difficulties in the prepn. and application of coating mixts. contg. satin white and blanc fixe; variations in the other materials employed and in coating procedure influence largely the proportion of adhesive required to produce coated papers of satisfactory printing qualities; printing conditions encountered by coated papers vary widely. A. P.-C.

The manufacture of parchment paper. M. DE KEGHEL. *Papyrus* **6**, 498-501, 524-6(1925); **7**, 27-30(1926).—Detailed description of its manuf., properties and uses. A. PAPINEAU-COUTURE

The influence of water on paper fibers during the manufacturing processes. SIGMUND SMITH. *Tech.-Wiss. Teil, Papierfabr.* **23**, 41-2(1925).—Water acts on paper fibers not only to effect a swelling but also to soften them. Unbeaten fibers, which are not swollen, are stiff but slightly elastic; beaten and swollen fibers are soft and plastic. If the water is pressed out of the latter, they become more like unbeaten fibers in their behavior. Vol. measurements on samples of unbeaten and beaten pulps and rag stocks are tabulated. J. L. PARSONS

Methods for the determination of the size of the particles in paper fillers. RUDOLF LORENZ. *Tech.-Wiss. Teil, Papierfabr.* **23**, 753-9(1925); **24**, *Tech.-Wiss. Teil*, 33-6, 74-6(1926).—Part of a series of articles concerning the colloid chemistry of paper fillers and methods for the detn. of the size of the particles. A brief review of the literature is given. Paper fillers belong to the class of coarse suspensions, but a good filler may approach the limits of a colloidal dispersion. Clay consists of relatively coarse primary particles, which are composed of much smaller secondary particles combined in an electrostatic manner. The technic of measurement of large particles by optical methods, such as the microscope and the ultramicroscope, and by filtration methods, is discussed. The Nöbel, Schone and Schurecht elutriating app. are described. Elutriation processes, however, are not satisfactory for detg. the size of filler particles. The automatically registering sedimentation app. of Sven Oden (*cf. C. A.* **14**, 2116) is described. Neither this method nor the procedure of Mohr is recommended. Elaboration is made of the elutriating app. of Wiegner-Gessner and the flocculation measuring app. of Wo. Ostwald and F. V. v. Hahn. A photographic device for continuously recording the results of the Gessner app. is described. J. L. PARSONS

Bleaching paper fibers with bleaching powder. O. HEIJNE. *Svensk Pappers-Tid.* **28** 510-1, 537-9(1925).—A résumé of theoretical speculations regarding the compn. of bleaching powder, methods of using the powder, recent investigations on its industrial application, and the effect on it of CO_2 . H. recommends the use of catalyzers to hasten the bleaching action. W. SEGERBLOM

Preparation of bleach solutions. ANON. *Zellstoff u. Papier* 5, 485(1925).—The use of an app. (German patent 316,797), invented by G. Braam, for the manuf. of bleach soln. from Cl gas and NaOH is described. The device permits of an accurate measurement of the gas absorbed. J. L. PARSONS

High-density bleaching. A. D. MERRILL. *Paper Trade J.* 82, No. 8, 161-2 (1926); *Paper Mill* 49, No. 9, 196, 198(1926); *Paper Ind.* 7, 2025, 2027(1926).—A discussion of the advantages of high-density bleaching, based on observations of mill-scale operations; and of the advantages of the continuous over the batch method of bleaching, the most important of which are: saving in bleach, time, labor, fiber and first cost of installation, and easier and more accurate control of the bleaching. A. P.-C.

Hardinge system of white water treatment. NOEL CUNNINGHAM. *Paper Trade J.* 82, No. 8, 223, 225(1926); *Paper Mill* 49, No. 9, 110, 112(1926); *Paper Ind.* 7, 1993, 1995(1926).—The system consists essentially of a filter-thickener and a filter-clarifier, such as are used in metallurgical ore dressing, combined in a single rectangular tank, and communicating at the top by pipes through which water overflows from the thickener into the clarifier. White water is admitted into the thickener behind a baffle which forces the incoming flow to a considerable submergence, and sedimentation takes place, assisted by a bottom filter action which can be controlled to effect greater or less deposition of fiber. The water, freed from suspended fiber, carries off slime, etc., into the second compartment, or clarifier, where sedimentation assisted by a comparatively large bottom filter action produced by a strong pump suction collects most of the remaining solids in a cake on the filter surface. A. PAPINEAU-COUTURE

The significance of the α -cellulose test for the pulp industry. J. L. PARSONS. *Paper Trade J.* 82, No. 8, 211-5(1926); *Paper Mill* 49, No. 9, 126-30(1926); *Paper Ind.* 7, 2019-23(1926).—Discussion of the significance of the α -cellulose detn., the necessity for its investigation, and the agencies which are at present working on the problem. P. obtained very concordant results by Jentgen's method (*Kunststoffe* 1, 165(1911)) modified as follows: the pulp and alkali mixt. is stirred intermittently during the 30-min. period; the pulp mass is filtered directly, with no previous addn. of water on a 9-10 cm. Buchner suction filter, the fibers acting as their own filtering medium, the filtrate being again passed through the funnel to remove traces of fibers; the mercerizing container is rinsed and the mass given a preliminary washing with 100 cc. of 5-8% NaOH; 40 cc. of hot 10% AcOH is used; the α -cellulose is dried in a glass-stoppered weighing bottle at 105° to const. wt. A. PAPINEAU-COUTURE

Testing of roofing paper. W. HERZBERG. *Tech.-Wiss. Teil, Papierfabr.* 23, 806-7 (1925).—The standard German requirements for roofing paper are (1) the raw materials must consist of rags, waste material from the textile industry, or old paper; the direct addn. of groundwood, straw pulp, peat, sawdust or mineral fillers is forbidden; (2) the max. ash content shall be 12%; (3) the max. moisture shall be 12%; (4) the sample shall absorb at least 120% of its wt. in anthracene oil in 5 min. at room temp.; and (5) paper of standard thickness (333 g. per sq. m.) shall possess a tensile strength (strips 15 mm. wide) of at least 4 kg. in the wire direction. The results of 63 tests on roofing papers are summarized, over 78% of which were up to standard. J. L. P.

Electrical gas purification for the pulp industry. E. ZOPF. *Wochbl. Papierfabr.* 56, 1540-1(1925); *Tech.-Wiss. Teil, Papierfabr.* 24, 38-43(1926).—Elec. purification of SO₂ gas by the Cottrell-Moeller process is described. The purification efficiency may exceed 99%. The removal of Fe₂O₃ dust, and the sepn. of As and Se from S burner gas tend to prevent the formation of SO₃. J. L. PARSONS

The turbidity of fillers. E. BELANI. *Zellstoff u. Papier* 5, 481-2(1925).—The Olszewski-Rosenmuller half-shade photometer is claimed to be the best and most rapid device for evaluating the turbidity of paper fillers for practical mill control. J. L. PARSONS

The chemical reactivity of pulp and its significance in the sizing of paper. ERIK ÖMAN. *Svensk Teknisk Tid.* No. 22, 176(1925); *Tech.-Wiss. Teil, Papierfabr.* 23, 725-7, 800-2, 813-6(1925).—When sulfite pulp, previously treated with a 0.1% Al₂(SO₄)₃ soln. and washed with water, is immersed in a dil. H₂SO₄ soln. (p_H 3.53), the H-ion concn. of the soln. is decreased to p_H 4.06. Sulfite pulp treated similarly, with the exception of the Al₂(SO₄)₃ soln., showed a p_H 4.35. The extent of the decrease in H-ion concn. varies indirectly with the no. of treatments with the dil. acid. When the pulp, so treated, is washed, a small portion of the ions is recovered, the reaction being reversible. Sulfite pulp in a weakly acid soln. is positively charged; the corresponding negative charge is present in the water as SO₄ ions. It is shown in an analytical manner that this is the case and that the greater portion of H-ions has disappeared. In a weakly alk. soln. (p_H 9.6) sulfite pulp is negatively charged as a result of the reaction

between the OH ions and the H ions forming undissocd. water. The isoelec. point of pulp does not occur at the neutral point (p_H 7.0), but on the acid side (p_H 5.5–6.0) when subjected to acid treatment. If OH ions are added, the isoelec. point is displaced towards the alk. side. The properties of paper made from such a pulp are probably affected in some degree. Sulfate pulp yields many more OH ions than sulfite pulp; the isoelec. point of the former is on the alk. side. Sulfite and sulfate pulps are amphoteric substances. The influence of a wash water with varying H-ion content, in the com. washing of sulfite pulp, tends to displace the isoelec. point of the pulp. In the sizing of paper stock the negatively charged rosin particles are attracted to the positively charged fibers and combine with them. The positive charge on the fibers is due (1) to the absorption of the Al ions, and (2) to the slight acidity of the $Al_2(SO_4)_3$ soln. The term "ionic dispersed soln." refers to an aq. pulp suspension which contains an excess of either positive or negative ions in the soln. A new kind of elec. potential is set up. The results of colorimetric and electrometric H-ion detns. correspond to the theory for the amphoteric character of pulp. J. L. PARSONS

The resolution of plant material by means of nitric acid according to the process of the Dresden Textile Research Institute. PAUL KRAIS. *Wochbl. Papierfabr.* 56, 1513–7 (1925); *Tech.-Wiss. Teil, Papierfabr.* 23, 797–9 (1925).—For the manuf. of pulp from Argentine reeds, straw, sugar cane, other tropical plants and wood chips, etc., under atm. pressure, equimol. amts. of KNO_3 and H_2SO_4 were satisfactory. A soln. contg. 3–5% HNO_3 was sufficient to resolve these raw materials into fibers after a digestion period of 6–8 hrs. at 95–96°. After removal of the acid, washing and neutralizing with CaO and Na_2CO_3 , the mass was easily broken into its fibrous constituents. Washing and bleaching operations follow. A brief review is given of other digestion processes involving HNO_3 . A Krupp Cr-Ni steel was practically resistant towards the action of the chemicals. In the digestion process the acids are allowed to act until the non-cellulosic constituents are oxidized, whereby the concn. of the acid is decreased so that the cellulose is not materially damaged. Straw pulp by this process yields a longer fiber and is stained more intensively by methylene blue than sulfate straw pulp. The economy of the process is briefly discussed. J. L. PARSONS

The colloidal nature of sizing with resins. E. ØMAN. *Svensk Pappers-Tid.* 29, 82–4 (1926).—Concd. sulfite causes much trouble in resin sizing. Ø. discusses 2 theories of the use of Al compds. in sizing involving (a) hydrolysis into colloidal $Al(OH)_3$ and (b) the taking up by the fiber of positive Al and subsequent addition of negative resin. Ø. suggests that the second theory more logically explains the differences in the amts. of resin needed by different plants to produce the same sizing results. Other metals, such as Cr, Fe, Cu and Zn, may be substituted for Al. W. SEGERBLOM

Sizing paper with resin. E. ØMAN. *Svensk Pappers-Tid.* 28, 534–7, 561–3, 585–7, 611–2 (1925).—A summary of work done by different investigators from Øllig in 1807 to date on the use of resin in sizing paper, the use of alum with resin, the effect of resin size on sulfite cellulose, the presence in sulfite cellulose of substances injurious to resin size, and the value of detg. the H-ion concn. W. SEGERBLOM

Effect of iron in sizing paper with resin. E. ØMAN. *Svensk Pappers-Tid.* 28, 483–4, 508–9 (1925).—In sizing the fibers take up Fe from ferric compds. but very slightly from ferrous compds. Ferric compds. are more harmful than ferrous compds. to the color of the paper. The Fe in ferric compds. acts the same as Al in alum in fixing the resin on the fiber. To this extent Fe is helpful. Fe-contaminated alum contains both ferrous and ferric compds., but more of the former. Alum contg. 0.4–0.5% Fe (ferric) is not harmful to white paper and 0.2% Fe (ferric) apparently has no effect on the color. W. SEGERBLOM

Rancidity of oils and its effects on the telegraph perforator tape. W. OGAWA AND S. MIZUSHIMA. *Researches Electrotechn. Lab., Japan* No. 159, 25 pp. (1925).—The cause of deterioration of telegraph perforator tapes now in use in Japan was studied. It was attributed to the rancidity of vegetable oils with which the tape is impregnated. Neutral mineral oil was found to protect the paper tape from deterioration by heat or light and is recommended as suitable impregnating medium. W. OGAWA

Electrification of paper-making machines. S. A. STAEGE. *J. Am. Inst. Elec. Eng.* 45, 272–81 (1926). C. G. F.

Wagner stationary recovery furnace for soda and sulfate mill chemical recovery. C. L. WAGNER. *Paper Trade J.* 82, No. 8, 177, 179 (1926); *Paper Mill* 49, No. 10, 44 (1926).—Description of the Wagner furnace, designed to take the place of rotaries and leachers in soda mills and of rotaries and smelters, with or without disk evaporators, in sulfate mills. The concd. black liquor, at about 35° Bé., is sprayed into the furnace without addn. of auxiliary fuel, and the heat used for steam raising. The fused

ash flows directly into the dissolving tank.' Careful regulation of the air is required with sulfate black liquor, but not with soda liquors. Discussion of the heat balance shows that the amt. of steam generated is almost sufficient for digesting, evapg., causticizing and bleaching; and that by the use of high-pressure turbines power may also be derived, so that the pulp mill can be made practically independent of outside fuel. Less heat is recovered from sulfate than from soda black liquors. A. PAPINEAU-COUTURE

Lime-sludge analysis. R. H. STEVENS AND A. J. ABRAMS. *Paper Trade J.* **82**, No. 8, 243(1926); *Paper Ind.* **7**, 2001(1926).—Filter 100 cc. of the well-mixed slurry (or 10 g. of the filter cake dild. to 100 cc. with distd. H_2O) on a Buchner funnel, stir the residue with 100 cc. of distd. H_2O for 5 min., filter, make the combined filtrate to 250 cc. (A) and dry the sludge (B) at 95–105°. Det. total solids by drying 25 cc. of original slurry to const. wt. To det. free CaO, ppt. the Fe and Al_2O_3 in an aliquot of A, and det. total CaO in the filtrate by pptn. as CaC_2O_4 and ignition to CaO . This is sufficient for routine control work; but for specially accurate work stir 1 g. of B for 10 min. with 450 cc. of distd. H_2O , filter, make up to 500 cc., and titrate an aliquot with 0.1 N HCl to methyl orange end point, and add the amt. of CaO so found to the amt. found in A. To det. total Na_2O , titrate an aliquot of A with 0.1 N HCl to methyl orange end point, calc. to Na_2O , correct for the free CaO previously found in A, and add the Na_2O present as sulfate, detd. by pptn. in A with $BaCl_2$ as usual. To det. $CaSO_4$, boil 1 g. of B with dil. HCl, filter off any insol. material, and ppt. with $BaCl_2$ as usual. A. PAPINEAU-COUTURE

Report of the Committee on Waste (of the Technical Association of the Pulp and Paper Industry). G. D. BEARCE, *et al.* *Paper Trade J.* **82**, No. 8, 143–6(1926).—A review of the present status of waste in the pulp and paper industry, showing recent progress in its elimination. A. PAPINEAU-COUTURE

Cellulose esters. SOC. CHIMIQUE DES USINES DU RHÔNE. Brit. 237,567, July 28, 1924. Esterification of cellulose, as in making cellulose acetates, is facilitated by a preliminary treatment of the cellulose with a small quantity of HOAc such that there is formed with the moisture present in the cellulose an acid of preferably 70–85% strength. The treatment is preferably applied to celluloses which have been treated with alk. liquors.

Cellulose acetate. KETOID CO. Brit. 237,591, July 22, 1924. Cellulose or hydrocellulose is treated with ketene alone or in the presence of an inert solvent such as C_6H_6 , toluene, kerosene and benzene, or of glacial HIOAc or Ac_2O which serves to moisten the cellulose before the addn. of the ketene. $ZnCl_2$, chlorosulfonic acid, H_2SO_4 or other catalysts may be used.

Cellulose acetate films. L. J. MALONE AND S. J. CARROLL. U. S. 1,575,778, March 9. Transparent flexible films are made from acetone-sol. cellulose acetate, solvent such as acetone, castor oil and acetylene tetrachloride or other "transparency inducing" substance.

Regenerating black liquor. A. H. WHITE. U. S. 1,575,473, March 2. Black

liquor from the sulfate pulp process is concd. and subjected to destructive distn., the residue is calcined together with CaCO_3 to form a mixt. of CaO , Na_2CO_3 and Na_2SO_4 and this calcined material is caused to react with carbonaceous material at a temp. of 300–900° (usually about 600–700°) in the absence of air until the sulfate is reduced and is leached to recover the sol. salts.

Diffusion apparatus for recovery of caustic alkali from waste liquor, etc. VISCOSSE CO. Brit. 237,468, Oct. 23, 1924.

Pulp articles treated with sulfuric acid. A TINGLE. U. S. 1,575,290, March 2. Food receptacles or other articles pressed from ligneous pulp are treated superficially with H_2SO_4 of about 57° Bc. strength to render them impervious. The acid is then neutralized and the article dried.

Fiber-board from bagasse. T. B. MUNROE. U. S. 1,574,254, Feb. 23. Piled bagasse is subjected to acetic fermentation until the fibers are partially loosened from the bundles in which they occur. The fermentation is stopped before the strength of the fibers is impaired, the material is mixed with fibers from wood, cooked, refined and mixed with fire-resisting material and formed into fiber-board.

Paper-making. K. SVEN. Brit. 237,292, July 21, 1924. Retention of an unusually large proportion of fillers in paper pulp is facilitated by the addn. of auxiliary substances which form colloids with the mordants such as soap solns. especially of the fatty acids, rubber emulsions, gelatin, glue, casein and solns. of inorg. substances such as alkalies, NH_3 , sol. silicates, lime or Ca salts. China clay "mordanted" with Al sulfate may be used as filler.

Felt for the drier portion of paper and pasteboard machines. E. v. ASTEN. U. S. 1,574,592, Feb. 23. Drier felts comprize an inner strengthening core of vegetable textile fiber and an outer layer of asbestos. U. S. 1,574,593 specifies felt made of threads each comprizing a core of worsted yarn with a coating of wool roving.

Bleaching paper pulp. R. B. WOLF. U. S. 1,576,018, March 9. A mixt. of pulp and a bleaching agent is caused to pass in a relatively thin layer in contact with air substantially free from gaseous decompn. products of the bleaching reaction. An app. is described.

Protected paper currency, etc. P. A. SAWYER. U. S. 1,575,940, March 9. A design is printed on paper with ink adapted to give strong adherence with the protective coating employed and, after drying, both sides of the paper are sprayed with a thin soln. of cellulose nitrate or other cellulose ester in a volatile solvent and dried.

Preventing froth on paper machines. J. A. DE CEW. U. S. 1,573,814, Feb. 23. FeSO_4 or other sol. Fe salt is used for pptg. sol. frothing ingredients of paper pulp which has been treated with rosin size and alum.

Paper-making apparatus. A. ALDRICH. U. S. 1,576,126, March 9.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

The stability of explosives considered as an additive property. M. TONEGUTTI. *Ann. chim. applicata* 15, 542–7 (1925).—Expts. were carried out to det. whether the stability of mixts. of different grades of ballistite or of cordite is an additive property (arithmetic mean) of the stabilities of the 2 components, as it is with mixts. of stable and unstable nitrocellulose (cf. Lenze and Pleuss, *C. A.* 14, 3531; de Bruin, *C. A.* 16, 1317). For this purpose the method of Taliani (*C. A.* 16, 342) was chosen as the most precise, the results being shown in the form of decompn. curves similar to his. With mixts. of ballistite, or of cordite of different origin and stability, the stability of the mixt. is equal to the arithmetic mean of the stabilities of the components. On the other hand, with heterogeneous mixts., i. e., with mixts. of ballistite and cordite, the stability of the mixt. is much greater than the arithmetic mean of the stabilities of the components, is in fact the same as that of the more stable component, in this case the cordite. This anomaly is probably due to the vaseline in the cordite exercising a retarding action on the decompn. of the less stable component, the ballistite. C. C. DAVIS

The reaction of nitroglycerin powders to the Angeli test and the relation between this reaction and their stability on being heated. M. TONEGUTTI. *Ann. chim. applicata* 15, 548–54 (1925).—Expts. were carried out to det. whether there is a relation between the acidity of an explosive of the ballistite type and its stability towards heat. The acidity in all cases was detd. by the method of Angeli (*C. A.* 13, 262; 16, 4064). It was found in general that ballistite with an acid reaction is less stable on being heated than neutral ballistite, whether this stability is detd. by the method of Taliani (*C. A.*

16, 342) or by the silvered-vessel test (cf. Marshall, *C. A.* 11, 2407, 3437). On the other hand, in confirmation of the work of Taliani (*loc. cit.*) no relation could be found between the acidity and the stability detd. by the Abel test (cf. Angeli and Errani, *C. A.* 14, 2858). The Abel test is not a criterion of the stability of an explosive on being stored. Neither can a ballistite be regarded as stable by the mere fact that it has a neutral reaction judged by the Angeli method. To obtain an adequate judgment of the keeping qualities of a ballistite, not only must its neutrality be detd. but also its stability according to the Taliani and silvered-vessel test. These 3 tests together are a satisfactory criterion of the keeping qualities. Like ballistite, cordite with an acid reaction is less stable than neutral cordite, but in contrast to ballistite, the Abel test is a better criterion of the stability of cordite than either the Taliani or silvered-vessel test, these last 2 tests revealing no difference in stability between acid and neutral cordites. As in other work (cf. preceding abstr.) this dissimilarity between ballistite and cordite can be explained by the vaseline having a stabilizing action on the decompn. of cordite. This was proved by the fact that the addn. of 5% vaseline to an acid ballistite which was far less stable than a neutral one rendered it just as stable as the neutral one. The silvered-vessel test is, however, a valuable criterion of the relative stability of cordites of different formulas, and of the amt. of nitroglycerin or of vaseline in a given cordite.

C. C. DAVIS

Liquid oxygen as an explosive. F. W. O'NEIL AND HERMAN VAN FLEET. *Trans. Am. Inst. Mining Met. Eng.*, Feb., 1926, No. 1562-A, 42 pp.—The authors seek to describe the present status and possibilities of LOX from results of investigations, research and practical use in this country during the past 4 years, and they conclude that LOX is admirably adapted for quarry work and open-pit mining; the cost of LOX for this work was much less than that of dynamite; the danger of digging into missed holes is eliminated; there is no difficulty in handling the material or charging the holes; the amt. of labor needed to load holes with LOX is less than that with dynamite, as the cartridges are simply dropped into the holes and no ramming is necessary; as there are no lights in open-pit work, there is no danger of the cartridges catching fire. Even should they do so from sparks from steam shovels or locomotives, their burning in the open air would involve no serious consequences. Of special interest are the detailed statements of costs for producing liquid O, and of LOX cartridges. Approx. 400 varieties of C and other blacks were tested as absorbents, and many varieties of paper for cartridge wrappers.

CHARLES E. MUNROE

Variations in the color of smokeless-powder grains. A. J. PHILLIPS. *Army Ordnance* 6, 384-6(1926).—The yellowish brown color which occurs in nitrocellulose for smokeless powder and in smokeless powder grains, made from under-bleached cellulose, have been attributed to Fe but the minute quantity of Fe found in the ash renders this unlikely. P. ascribes it to oxidation of an unknown kind. When the stabilizer, diphenylamine, is introduced various colors, deep brown, greenish brown, dark green, greenish black, or black, may appear. It has been believed that when the grains became black the stabilizer was exhausted, but such is not the case for several of the oxidation and nitro derivs. of Ph₂NH are almost as efficient stabilizers as Ph₂NH itself. It is generally assumed that the black color is due to phenazine. Microscopic examn. of thin sections of black grains show them to have a pale yellow-green color and the apparent blackness is attributed to the presence of variously sized particles, formed in the oxidation of Ph₂NH, in colloidal suspension, and because of the size and shape of these particles light is so absorbed and diffracted as to give to the grains various colors down to black.

CHARLES E. MUNROE

Explosion hazards from the use of pulverized coal at industrial plants. L. D. TRACY. *Bur. of Mines, Bull.* 242, 103 pp.—A description is given of pulverized-coal systems with their driers, pulverizers and distributors, including a discussion of the various hazards of prepn., storage and use with illustrations from disasters. There is given a set of operating regulations through the observance of which explosions may be avoided.

CHARLES E. MUNROE

Fulminating material. Energy per cubic centimeter and per gram at the instant of explosion. E. MATHIAS. *Compt. rend.* 182, 194-7(1926); cf. *C. A.* 20, 1199.—Conclusions reached by 2 independent lines of physico-mathematical reasoning lead to the results 3300 and 2860 kg. m. per cc. resp. for the pure fulminate at the instant of its destruction, or about 4 times the figure for nitroglycerin.

L. W. RIGGS

The pressures developed on explosion of gaseous mixtures at high densities. W. T. DAVID. *Phil. Mag.* [7] 1, 334-7(1926).—Recent work of Bone, Newitt and Townend (*C. A.* 19, 3581) showed that during the explosion of inflammable gas mixts. the ratio of max. pressure developed to the initial pressure of the mixt. before explosion increases

as the initial pressure increases. B., N. and T. suggest the effect may be due to an increase with pressure in the opacity of the gases to radiation emitted during the explosion, thus retaining a higher percent of heat in the gas phase the higher the initial pressure. D. regards this explanation insufficient and considers several other causes such as: departure of the gases from Boyle's law; more rapid equil. between vibratory, rotational and translational energies; smaller heat loss during the explosion period; less dissoc.; more complete combustion at moment of max. pressure; and decrease in sp. heat of gaseous products of combustion at the high temp. developed as the density of the gaseous mixts. increases. Of these D. regards the last two as most important, especially the last one, which is discussed briefly.

S. C. LIND

Amended regulations for the transportation of explosives and other dangerous articles by freight and express. I. C. C., No. 3666. Pamphlet, 15 pp., Feb. 23, 1926. Wash. Govt. Printing Office.—These amended regulations of the I. C. C. become effective July 1, 1926.

CHARLES E. MUNROE

A half century in chemical education. Record of the scientific contributions of Charles Edward Munroe (TAYLOR) 2.

Drying nitrostarch. J. B. BRONSTEIN. U. S. 1,573,673, Feb. 16 A slurry of nitrostarch is placed in long narrow tubular fabric bags and these are exposed to a drying atm.

Impregnating match splints. W. J. ELDER and C. N. MOREHOUSE. U. S. 1,574,238, Feb. 23. Splints are treated with a spray of concd. soln. of NH_4 phosphate or other material which will prevent after-glow.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Azo dyestuff technology. IV. **Manufacture of Direct Deep Black E.** W. C. WHITEHEAD. *Chem. Trade J.* 77, 206-7 (1925). V. **Manufacture of Fast Sulfone Black.** *Ibid* 265; cf. C. A. 19, 3022.

E. H.

Problems of chain warp vat dyeing. C. R. EPHLAND. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 97-8; *Am. Dyestuff Rept.* 15, 165-6.—Among the advantages of chain dyeing are less crocking, brighter and cleaner shades and probably the most uniform method outside of raw stock dyeing.

L. W. RIGGS

Dyeing rayon with vat colors. M. T. JOHNSON. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 94-7; *Am. Dyestuff Rept.* 15, 162-5.—A short paper followed by a long discussion by the members.

L. W. RIGGS

Importance of technical men to the textile industry. E. C. BROOKS. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 90-4; *Am. Dyestuff Rept.* 15, 158-62.—The co-operation of schools of agriculture, engineering, science and business with textile schools is stressed. The study of cotton fiber should begin on the farm.

L. W. RIGGS

Comparison of the affinity of cotton, wool, and particularly of cellulose acetate silk for azo compounds (dyestuffs) containing sulfonic, carboxyl, arsonic and stibonic acid groups. A. J. HALL and M. I. AISCHER. *J. Textile Inst.* 17, 104-10T (1926).—The dyes used were α -naphtholazophenyl-4-sulfonic acid, β -naphtholazophenyl-4-sulfonic acid, phenolazophenyl-4-sulfonic acid and salicylic acid-azophenyl-4-sulfonic acid, and these same basic groups were severally combined with carboxylic, arsonic and stibonic groups, resp., making 16 dyes in all. Wool, cotton and acetate cellulose were dyed with each dye and the colors and fastness to boiling water, soap and light of each sample were noted. Conclusions: Cellulose acetate silk and cotton have but little, and wool has considerable affinity for all of the azo compds. above mentioned. All the dyeings on wool have approx. equally good fastness to boiling water but have little fastness to boiling soap. Dyes contg. the stibonic acid group are less fast than the others. Azo compds. contg. stibonic acid groups have a greater affinity than the corresponding compds. contg. arsonic acid groups for cellulose acetate silk, but these differences cannot be correlated to differences in the solubilities of the azo compds. in water. Azo compds. contg. β -naphthol have a greater affinity than compds. contg. α -naphthol for cellulose acetate silk. The affinity of cellulose acetate silk for azo compds. contg. sulfonic, arsonic, stibonic and carboxylic acid groups increases in the order named. Although none of the organo-azo-As and Sb compds. described above is suitable as dyestuff for cellulose acetate silk, it is believed that satisfactory dyes contg. these acid groups may be prepd.

L. W. RIGGS

New method for the estimation of alkali with special application to wool. H. R. HIRST AND A. T. KING. *J. Textile Inst.* **17**, 94-100T(1926).—Existing analytical methods, when applied to the detn. of alkali in wool, do not give correct results. Wool placed in water contg. terephthalic acid in suspension yields all of its alkali to the acid as Na terephthalate in soln. The Na terephthalate thus formed may be estd. gravimetrically by filtering out the unchanged terephthalic acid, adding dil. H_2SO_4 to the filtrate to convert the Na terephthalate to terephthalic acid and filtering and weighing this. This method is used with dyed fabrics which bleed and thus would obscure the indicator changes of the more accurate volumetric method. In the latter method, with bromophenol blue as indicator, a liquid contg. terephthalic acid and Na terephthalate remains purple until the whole of the salt is converted into acid, when a further addn. of H_2SO_4 changes the indicator. By this method a measured quantity of alkali, whether NaOH, Na_2CO_3 , or soap added to wool can be quantitatively recovered. By using this method in conjunction with that for estg. soap (*C. A.* **16**, 3212) the amts. of alkali present as soap and sorbed alkali, resp., can be detd. **Estimation of sulfuric acid in wool.** *Ibid* 101-3T.—A measured vol. of standard Na terephthalate is added to the wetted sample of wool and the subsequent procedure is the same as that described for the estn. of alkali. L. W. RIGGS

The sulfur content of wool. S. R. TROTMAN AND H. S. BELL. *J. Soc. Chem. Ind.* **45**, 10-2T(1926).—The S content of wool as given in the literature ranges from 0.5 to 5.4%. The object of this study was to det. if such differences actually exist in samples of known origin and purity. The wide differences hitherto reported in the S content of wool are caused largely by the different methods of analysis. The various methods for the detn. of S in org. material were examd. critically, and their actual or possible errors are indicated. The method of analysis adopted was that of Benedict-Denis (cf. *C. A.* **5**, 114, 1287, 1448) modified as follows: About 0.2 g. of wool is warmed with a little NaOH soln., made from metallic Na, till it is just dissolved. A few drops of Br are added and after a few min. the soln. is neutralized with HNO_3 ; 10 cc. of the Benedict-Denis reagent is then added and the detn. is completed according to the Benedict-Denis procedure. The sample of wool for analysis is purified by extn. in a Soxhlet app. with petr. ether and alc. and then washed with hot water. The results on a sample of "Botany web" ranged from 3.06 to 3.30, av. 3.19% of S. The unmodified Benedict-Denis method gave 3.24% of S. The narrow limits of variation in the S content of wool would be expected if keratin or wool protein is a definite chem. compd. L. W. RIGGS

The retting of flax with *Plectridium pectinovorum* (*Amylobacter A. M. Bredemanni* and *Bacillus felsineus* Carbone. G. RUSCHMANN AND W. BAVENDAMM. *Centr. Bak. Parasitenk., II Abt.* **65**, 43-58(1925).—In Germany, *B. felsineus* does not play an essential role in the fermentation of pectin. JOHN T. MYERS

An investigation on the strength and breaking point of artificial (viscose) silk. P. KRAIS. *Z. angew. Chem.* **39**, 196(1926).—An extension of the use of the author's app. gave a more accurate detn. of tensile strength and breaking point of viscose fibers. Single fibers gave an av. of 11.5 g. tensile strength, 31.7% breaking tension at 52% relative humidity and 22°; 8.7 g. and 41.7% at 86% and 17°. Tests in H_2O gave 6.7 g. and 41.7% at 55% and 26°. The effect of very wet air and H_2O is the same. A loss of 41.3% in strength is accompanied by a stretch of 20%. Yarn acts less favorably, losing 57% strength with very little stretch. CECIL E. P. JEFFREYS

Determination of α -cellulose content in artificial-silk cellulose. H. E. WAHLBERG. *Svensk Pappers-Tid.* **28**, 641-2(1925).—Duplicate analyses by the Waentig method showed that results from air-dried material ran lower than results from undried material varying from 1.6 to 6.4% for 7 detns. Corresponding differences for similar analyses by the Jentgen method were 0.1 to 0.6%. One sample dried over Sunday in a drying oven at 110° gave 65.9% α -cellulose in a material which should have given 83%. W. S.

Laboratory preparation of viscose. E. H. MORSE. *Ind. Eng. Chem.* **18**, 398-400(1926).—The prepn. described is intended to be carried out in a factory lab. Sulfuric cellulose is used. The steps described are as follows: treatment with NaOH, presouring, crumpling, xanthation, soln. of xanthate, ripening, filtration and subjection to vacuum reduction to the proper viscosity and pptn. L. W. RIGGS

The mill chemical laboratory—Its coördination with the mill purchasing department. H. B. BURKE. *Am. Dyestuff Rept.* **15**, 149-52(1926).—It is shown how a properly organized and equipped lab. becomes a source of profit especially in the purchasing department. Five sample specification sheets for materials bought are shown, and an example of the system in operation is given. L. W. RIGGS

The processing of furs. WM. D. BAIRD. *Am. Dyestuff Rept.* **15**, 115-7, 171-4

(1926).—The topics discussed are the following: factors affecting the characteristics of furs such as food, climate, season, age and species, fur structure, prep. furs for dyeing by a process called killing to increase the affinity of the fur for the dyestuff, mordanting and dyeing. Details of dyeing and of colors used are given. L. W. RIGGS

Time factor in hair testing. J. C. MANN AND F. T. PEIRCE. *J. Textile Inst.* 17, 82-93T (1926).—The breaking load of a cotton hair varies in a logarithmic relation with the time allowed for the hair to stretch to the breaking point. The more time the hair is given to yield, the lower is its resistance at any given extension or at rupture because its elasticity is imperfect. In making tests this time element must be known quantitatively. L. W. RIGGS

Polysaccharides. XXXIII. Enzymic decomposition of artificial silk (KARRER, *et al.*) 11A. Sandalwood dyestuffs (DIETERLE, STEGEMANN) 10. Cellulose: Its chemistry with particular reference to the manufacture of rayon (ESSELEN) 23. Dialytic apparatus for recovery of caustic hydroxides from mercerizing solutions (U. Dyes. FARBERWERKE FORM. L. DURAND, HUGUENIN & Co. Brit. 237,295, July 21, 1924. The process described in Brit. 186,057 (C. A. 17, 343) is modified by the use of a primary or secondary base such as aniline or monoethylaniline in the conversion of leuco compds. of thioindigo or other vat dyes into esters of polybasic acids. Leuco-thioindigo, suspended in a mixt. of aniline and chlorobenzene at a temp. of 0° or lower, may be treated with chlorosulfonic acid.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 237,385, May 19, 1924. Indigoid dyes are prepd. by condensing 2,1-naphthindoxyl with 7-chloroisatin or 5,7-dibromoisatin or other halogen substitution products of isatin. These dyes produce brown to olive shades on cotton from the vat.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BAËLE. Brit. 237,375, May 8, 1924. Sulfuretted dyes are produced by treating a 2,5-diarylidobenzoquinone, other than a 3,6-dihalo-2,5-diarylidobenzoquinone, with a S halide or a sulfurous acid halide such as thionyl chloride. The products dye wool from the vat in yellow, orange, brown, violet, greenish and black shades. Numerous examples are given.

Dyes. J. FROHLICH. U. S. 1,575,678, March 9. Vat dyes which dye wool various fast brown tints are formed by the reaction of S dichloride on 2,5-diarylidobenzoquinones. U. S. 1,575,679 specifies dyes made from S monochloride and 2,5-diarylidobenzoquinones, which give with hyposulfite and NaOH bright yellow to brown vats from which wool is dyed fast yellow-brown to red-brown, olive-green, green and gray. Cf. C. A. 19, 2750.

Dyes from naphthalene derivatives. FARBERWERKE FORM. MEISTER, LUCIUS & BRÜNING. Brit. 237,294, July 21, 1924. The dianhydride of naphthalene-1,4,5,8-tetracarboxylic acid, or the acid itself, or its substitution products, is condensed with *o*-diamines, *e. g.*, with *o*-phenylenediamine in PhNO₂. The product dyes cotton yellowish red from a green vat.

Dyes of the anthraquinone series. J. BADDILEY and W. W. TATUM. U. S. 1,574,748, March 2. Dyes are formed of the general formula A-NH-SO₂-(1)C₆H₃-COOH(3)-OH(4) in which "A" represents an anthraquinone residue which may be substituted. They are acid dyes dyeing wool directly and also on a chrome mordant and also may be used on "acetyl silk." Among the starting materials which may be used are: diamino-anthraquinone or 1,4-diaminoanthraquinone or 1,4,5,8-tetraaminoanthraquinone and salicylic sulfo chloride. Cf. C. A. 20, 509.

Triphenylmethane dyes. FARBERFABRIKEN FORM. F. BAYER & Co. Brit. 237,096, July 18, 1924. Dyes derived from a benzaldehyde having a replaceable *p*-substituent such as Cl, NO₂, SO₂H, or CH₂O, and 2 mol. proportions of an *o*-hydroxybenzenecarboxylic acid are condensed with halogenated aromatic bases having *o*-substituents to the amino groups; *e. g.*, 4-, 5- or 6-chloro-2-toluidine, 4,6-dichloro-2-toluidine, 3-chloro-4-tol-

uidine, 4-chloro-2-anisidine, 4-chloroanthranilic ester and 1-chloroaminonaphthalene. The dyes produce on wool bluish red to reddish violet shades changed to fast red-violet by after-chroming.

Azo dyes. F. GÜNTHER. U. S. 1,573,605, Feb. 16. Azo dyes for animal, vegetable and mixed fabrics comprize the grouping $-N:N\text{-aryl}(p)\text{-X-(}p\text{)aryl-N:N-}$ (in which X stands for the azo or azoxy group or the urea grouping) coupled with an *o*-hydroxycarboxylic acid, sulfonic groups also being present. Among the starting materials which may be used for making the dyes are: *p*-nitroaniline-*o*-sulfonic acid and saileylic acid. The dyes generally produce orange to reddish brown shades.

Azo dye. J. HALLER. U. S. 1,576,322, March 9. Azo dyes giving reddish dyeings are prepd. from diazotized asym. *m*-xylydine compds. and 2,3-hydroxynaphthoic acid asym. *m*-xylydide compds.

Vat dyes. H. SCHÖPFER. U. S. 1,574,116, Feb. 23. Dinitroperylene or other nitro derivs. of perylene are heated to about 160–200° with AlCl_3 to produce dyes giving olive-brown or olive-green on cotton.

Dyes for treating photographic emulsions. E. J. WALL and D. F. COMSTOCK. U. S. 1,573,595, Feb. 16. A small fraction of 1% of gelatin is added to colloidal color-sensitizing dye solns. to restrain coagulation and pptn.

Dye intermediates. M. T. BOGERT. U. S. 1,574,337, Feb. 23. By reduction of 2,4-dinitrodiphenyl ether or of other 2,4-dinitroaminodiaryl ethers, products are obtained having the general formula $2,4\text{-(H}_2\text{N)}_2\text{Ar O.Ar}$, in which Ar is aryl. These intermediates yield dyes similar to those obtainable from *m*-phenylenediamine.

Dyeing and printing with vat dyes. M. BADER, T. LOMBARD, C. SUNDER and C. VAUCHER. U. S. 1,575,958, March 9. Thread, fabric or other goods are treated with a H_2O -sol. ester-like deriv. of a vat dye such as an indigo dye and the dyeing is then developed by an oxidizing agent, *e. g.*, a chromate.

Naphthalene diazo oxides and dyes. AKT.-GES. FÜR ANILIN FABRIKATION. Brit. 237,594, July 28, 1924. Acyloxy-4-sulfonaphthalene 1,2-diazo oxides are obtained by treating 6- or 7-hydroxy-4-sulfonaphthalene 1,2-diazo oxide with acid anhydrides or acid chlorides. They may be used to produce dyes by coupling with 1-aryl-3-methyl-5-pyrazolones. The products dye wool in orange to brown shades changed toward red by after-chroming. Various examples are given.

Dyeing. J. M. ESCHACH and J. P. WORMS. Brit. 237,157, Jan. 19, 1925. Animal fibers or tanned vegetable fibers are dyed by treatment with HNO_2 and metallic salt or oxides at temps. not exceeding 80°. Numerous examples are given for producing various colors.

Dyeing cellulose acetate or similar materials. W. DUISBERG and W. HENTRICH. U. S. 1,575,324, March 2. Cellulose acetate threads or other dyes used are of the type $R\text{-N:N-R'}$ in which $R\text{-N:N-}$ stands for the diazo deriv. of an acid-substituted aromatic nitro compd. and R' for an aromatic diamine; *e. g.*, the dye Na 4-nitro-1-benzoate 2-azomethylbenzylaniline gives clear orange shades.

Dyeing wool. C. S. BEDFORD. Brit. 237,054, May 22, 1924. Wool is dyed with chrome dyes such as hematin, fustic, quercitron bark, osage orange, alizarins, gallo cyanins, Mordant Yellow, Brilliant Alizarine Blue R, and Palatine Chrome Black, by sequence dyeing in which it is mordanted with 0.5% its wt. of $\text{K}_2\text{Cr}_2\text{O}_7$ or $\text{Na}_2\text{Cr}_2\text{O}_7$ in the presence of HCl and lactic acid. Various other details are specified.

Apparatus for carbonizing wool by use of acid. A. SHAW and B. SHARP. Brit. 237,420, July 9, 1924.

Dyeing apparatus. B. K. THIES. U. S. 1,576,378, March 9.

Dyeing apparatus. HUSSONG DYEING MACHINE CO. Brit. 237,428, July 29, 1924.

Dyeing apparatus. F. BROUGHTON and A. B. HENSHILWOOD. Brit. 237,056, May 14, 1924.

Apparatus for spray-dyeing. TWO-TONE CORPORATION. Brit. 237,230, July 16, 1924.

Apparatus for dyeing and washing cotton or woolen fabrics. J. BAILEY and E. GILL. Brit. 237,422, July 10, 1924.

Yarn-dyeing apparatus. G. T. THOMAYER. U. S. 1,576,013, March 9.

Yarn-dyeing apparatus. G. T. THOMAYER. U. S. 1,576,234, March 2.

Apparatus for dyeing and other treatment of yarn. JOHN BRANDWOOD and JOSEPH BRANDWOOD. U. S. 1,574,785, March 2.

Lakes. BRITISH DYE STUFFS CORPORATION, LTD., J. BADDILEY, R. S. HORSFALL, A. SHEPHERDSON and H. JACKSON. Brit. 237,457, Sept. 23, 1924. Lakes are prepd. by treating unsulfonated aminoöxyanthraquinones or their alkyl, aryl or nucleus substituted derivs. in a fine state of division with a compd. of a lake-forming metal, *e.*

a blue lake is formed by stirring and boiling a 10% paste of *N*-methyl-diaminoanthra-rufin and $\text{Al}(\text{OH})_3$. Various other examples are given.

Products from viscose. A. KAMPF. U. S. 1,575,210, March 2. In forming artificial silk or similar products unripened viscose is prepd. from unripened alkali cellulose and is "spun" in a bath of acid soln. having a temp. of about 4° . The acid bath contains only such org. substances and salts as are taken up by it during the "spinning" process. Cf. C. A. 20, 830.

Artificial silk threads from viscose. L. HESSE and H. RATHERT. U. S. 1,575,052, March 2. Alkali cellulose is treated with CS_2 in the presence of a reducing agent such as Na_2SO_3 and the xanthate formed is dissolved in alkali in the presence of reducing agents such as the sulfite. The soln. thus formed is injected into a soln. of Na_2SO_4 contg. a comparatively large quantity of H_2SO_4 .

Washing artificial silk. A. PINEL. U. S. 1,573,859, Feb. 23. The material is alternately and repeatedly washed by spraying and dried by centrifugal action.

Apparatus for spinning artificial silk. KOHORN & Co. and A. LEHNER. Brit. 237,214, July 17, 1924.

J-shaped stack, etc., for treating cloth in piled condition. HUNT & MOSCROP, LTD. and E. W. HUNT. Brit. 237,061, June 10, 1924.

Apparatus for recovering liquor for re-use from used laundry solutions. F. L. ROSENAU. U. S. 1,574,170, Feb. 23.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Report of Sub-Committee III on testing paint vehicles. H. A. GARDNER. *Proc. Am. Soc. Testing Materials* 25, Pt. I, 227-31 (1925).—Results of collaborative exposure tests at different stations showed fair agreement. The pigments used consisted of mixts. of ZnO with 50% (of the total) titanox, 50% lithopone, 70% titanox, and 50% white lead, resp.; they were ground in raw linseed oil to a paste contg. 80% pigment and 20% oil by wt., and reduced to painting consistency with varying amts. of oil, turpentine and liquid drier. On the whole, the titanox mixts. stood up best, and of the various reductions, those with least oil and most turpentine showed up best.

Report of Sub-Committee XXIII on anti-fouling paints. A. M. MUCKENFUSS. *Proc. Am. Soc. Testing Materials* 25, Pt. I, 244-7 (1925); cf. C. A. 19, 1783.—Results of a series of panel tests carried through during the summer of 1924 confirmed that the differences in fouling and corrosion are as appreciable in under-water paints by varying the vehicle as they are by varying the pigment.

Some chemical and physical characteristics of paint. A. K. LIGHT. *Chemistry & Industry* 45, 101-3, 122-3 (1926).—A brief discussion of the properties of numerous pigments, oils, driers and thinners, and an outline of some of the phys. and chem. requirements of a good paint.

New researches on the durability of paints. ANON. *Farbe u. Lack* 31, 41 (1926).—A review.

The question of anti-rust pigments. BEISSEL. *Farbe u. Lack* 31, 26 (1926).—A review of American practice.

Chemical pigment colors. A. F. BROWN. *Paint, Oil, Chem. Rev.* 81, No. 10, 11-16, 33, No. 11, 14, 16 (1926).—Prepn. and uses are reviewed.

Contribution to the valuation of white pigments. A. EIBNER. *Z. angew. Chem.* 39, 261-2 (1926).—A criticism of methods and results of Wolski (*Z. angew. Chem.* 38, 834 (1925); cf. C. A. 19, 3602) on measurement of hiding power.

United States Government master specification for shellac, flake orange. Bur. Standards, *Circ.* 302, 6 pp. (1926).

Experiments on asphalt japans. HERMANN MARCUS. *Farbe u. Lack* 31, 43 (1926).—A review of uses and a few formulas.

Cellulose nitrate lacquers. A. E. LAIN. *J. Oil Colour Chem. Assoc.* 9, 33-44 (1926).—British practice in selecting raw materials and manufg. is reviewed. With hard manilas and shellac, which are more sol. in alc. than in other solvents, alc.-sol. sectionable because of their odors, which persist for months. Ester gum, wnuue very ad- sol., has to be used in quantity equal to that of the cellulose nitrate to insure good adhesion. Its use, therefore, demands a high proportion of plasti-zizer to overcome

brittleness. Mastic also must be present in amt. equal to the cellulose nitrate to insure adhesion. Shellac gives better adhesion but the waxy constituents must first be removed by dissolving in methylated spirits and using only the clear liquid. R. J. M.

Light-fastness of lithopone. ANON. *Farbe u. Lack* 31, 54(1926).—A review of recent articles and patents. R. J. MOORE

Production of coal-tar color lakes. HANS HADERT. *Farbe u. Lack* 31, 3, 15, 30 (1926).—A comprehensive review of the composition and preparation of colors for various uses R. J. MOORE

The question of the drying of fatty oils. A. EIBNER. *Z. angew. Chem.* 39, 38–46 (1926).—See C. A. 20, 117. R. J. MOORE

United States Government master specification for ink, drawing, colored waterproof. Bur. Standards, *Circ.* No. 301, 4 pp.(1926). E. H

Pb and Zn pigments and salts in 1924 (SIEBENTHAL, STOLL) 18. Natural iron pigments (KURBATOV) 8. Light-sensitive varnish mixture for photographic use (U. S. pats. 1,574,356–9) 5.

Paint and varnish remover. G. BLENIO. U. S. 1,573,537, Feb. 16. Oil of mirbane to the extent of 15% or more is used with dissolved rubber and solvents such as C.H., acetone and chlorinated derivs. of hydrocarbons.

Powdered paint ingredient for use with either oil or water. M. TSUBATA. U. S. 1,574,854, March 2. Pigments such as ultramarine, ZnO or white lead are mixed with gelatin, formaldehyde and alc., the mixt. is dried and powdered, further mixed with gelatin, drying oil and alc. and this mixt. is also dried and powdered

Sizing for plaster walls. H. WOOD. U. S. 1,576,394 March 9. A major proportion of a mixt. of soap and glue in H₂O comprizes smaller proportions of linseed oil, turpentine, vinegar, japan drier and white lead.

Transfer ink. W. S. LAWRENCE. U. S. 1,573,976, Feb. 23. A fusible transfer ink releasable from a paper transfer base under the action of heat comprizes "cumar" or similar fusible base, a direct dye or other coloring material and Turkey red oil or other emulsifying agent which will cause the emulsification of the coloring material used when the ink is acted on by an alk. washing fluid, so that the dye is liberated and penetrates the fabric to which the ink is applied.

Colored printing ink. H. CAJAR. U. S. 1,576,408, March 9. H₂O is evaporated under a high vacuum from an aq. ink paste in a steam-jacketted levigating and mixing app. Cf. C. A. 19, 739.

Linoleum. G. DUBSKY. U. S. 1,576,181, March 9. A drying oil such as linseed oil is partially oxidized by heating and injecting air into it until it gelatinizes, filling material is added and air is injected into the mixt. at an elevated temp. while agitating it gently to complete the oxidation of the oil.

Resinous condensation products. C. A. NASH. U. S. 1,574,842, March 2. Before the final heat curing and hardening of synthetic resins formed from phenol and formaldehyde or similar substances, they are admixed with about 10% of stearin pitch and 3% of S to improve their molding properties.

Kauri gum. N. BUCHAN. Brit 237,576, July 23, 1924. Purified kauri gum is extd. from the crude gum by Et₂O alone or mixed with a hydrocarbon solvent such as C₆H₆. An app. is described which may be steam-heated.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Detection of coconut oil in cacao butter by means of the ethyl ester number. J. HANUS AND (MISS) B. KOMOROUSOVÁ. *Chem. Listy* 19, 394–7(1925).—The H ester no. is defined as the no. of cc. 0.1 N KOH necessary to saponify the Et esters of the distillate obtained from 5 g. fat after conversion of the glycerides into Et esters. The method lends itself to evaluation of coconut oil and cacao fat mixts.; the nos. for the pure fats being 23 and 3, resp., referred to 1 g. fat taken for analysis. F. C. K.

The use of sintered glass crucibles for the separation of the digitonin compound with sterol in testing fats for phytosterol. J. PRESCHER AND R. CLAUS. *Z. Nahr. Genussm.* 50, 420-3(1925).—An application of the sintered glass filtering medium (cf. C. A. 19, 794).

Chemical reactions of rancid fats. J. BULIR. *Chem. Listy* 19, 357-63(1925).—Altered fats contain active O and give reactions of peroxides. A convenient reagent for their detection is di-*p*-diaminodiphenylamine, but the analysis is more exact if KI is used. The recommended procedure is: 1 cc. of oil or fat is dissolved in 1 cc. petr. ether, 2 cc. of 20% soln. of KI in 90% alc. is added and the mixt. is shaken for 1 min. About 15 cc. H₂O is then added, shaken, and after the I₂ has passed into the aq. layer, a test is made with starch. If the fat is fresh, the soln. remains clear, but if altered, a faint-violet blue tint appears. Similar reaction is obtained with fats renovated by means of oxidizing agents. The peroxide reaction is sometimes negative with butter, even though the butter is very old and rancid. Atm. O is absorbed very rapidly by some fats, such as lard, and very slowly by others, such as cacao butter. This appears to be a function of the position of the unsatd. acid radicals in the mixed glyceride mol.

Soy-bean oil as soap-making material. A. A. HORVATH. *J. Assoc. Chinese Am. Eng.* 6, No. 7, 65-72(1925).—Soap manufd. from soy bean oil has exceptional lathering capacity. It is recommended for domestic use with the hard waters of north China.

F. C. KRACEK

WM. H. ADOLPH

Determination of viscosity of oils (BORODULIN) 22.

Decomposing fats, oils and waxes by sulfo acids. W. SCHRAUTH. U. S. 1,576,005, March 9. Cyclohexylnaphthalene sulfo acid or a similar sulfo acid of an aromatic hydrocarbon substituted in the nucleus by 1 hydrocarbon radical is mixed with the material to be decomposed, *e. g.*, fats, and with H₂O and the mixt. is heated to effect splitting.

Increasing stability of edible oils. H. BOLLMANN. U. S. 1,575,529, March 2. Immediately after purification of olive oil, soy-bean oil or other edible or "salad" oil a small quantity of lechthin (usually about 0.05-0.1%) is added.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Loss of sugar by inversion in sugar factories in northern India and its prevention by antiseptic measures. C. M. HUTCHINSON AND C. S. RAMAYYAR. *Agr. Research Inst., Pusa, Bull.* 163, 9 pp (1925).—Loss of sugar by inversion was found to be due to infection of the juice by bacteria, molds and yeasts which were present even after liming and passage through the first and second filter presses. Their presence in the latter stages of the process appeared to be due to air-borne reinfection. A yeast of the *Cerevisiae* type, a bacterium of the *Subtilis* group and an *Aspergillus* mold, all of which inverted sucrose rather rapidly were isolated. Other bacteria, molds and yeasts capable of inverting sucrose were isolated. In pure cultures about 6 hrs. were required for the first 3 organisms to produce invert sugar in measurable amts., after which time as much as 7% inversion occurred in 2 hrs. Disinfection of the machinery with a hypochlorite prepn known as "E. C." did to 1 part of Cl per 25,000 materially reduced inversion losses. It appeared that the action of the mass infection existing in the mills and in the channels leading to the liming vats was a cumulative one and owed its effectiveness to a rapidly gained condition of establishment and efficiency similar to that obtaining in a sewage filter bed in which event sterilization to the point of preventing the establishment of a mass infection of the surfaces in contact with the juice should eliminate serious loss of sugar by inversion.

K. D. JACOB

Milling problems of the Cuban sugar industry. H. EDSON. *Facts about Sugar* 21, 297-8(1926).—This article is intended to present a few of the unsolved problems in the mill room and gives the factors involved in increasing the efficiency of extn. Heavy milling, the necessity of variable-speed motors, gear efficiency, maceration methods and the advantage of shredding are emphasized.

T. MARKOVITS

Electrical conductivity as measure of the ash content of raw sugars. F. W. ZERBAN AND J. MULL. *Facts about Sugar* 21, 278-81(1926).—The elec. conl. app. as designed by Toedt is described and the applicability of the same for ash detn. in raw sugars

is presented. For comparison 3 methods were used in the tests (1) total sulfated ash, (2) sulfated ash in the water-sol. part of sugar and (3) ash by elec. cond. The tabulated results show that the agreement between sol. ash by the cond. method and sol. ash by the chem. method is in general very good. Comparison of results by methods (1) and (2) shows that in a no. of individual cases the sol. ash is apparently a little higher than the total ash although the difference of the av. is negligible. Previous literature is reviewed.

T. MARKOVITS

The estimation of errors in the determination of purity. P. F. BEARTS AND A. LECHAT. *Sucre Belge* 45, 37-43, 69-81(1925).—This paper gives the mathematical formulas which are to be applied for the calcs. of the various errors which may arise under various conditions in the detn. of the Brix reading and the polarization in routine operation in a large sugar lab. It is estd. that the final av. error in detg. the apparent purity may be 0.28 to 0.34, these being the sums of the probable relative errors of the several observations. Methods are given to reduce the different errors to a minimum.

T. MARKOVITS

Deterioration of raw sugar in storage. VII. WM. L. OWEN. *Facts about Sugar* 20, 760-3(1925); cf. C. A. 19, 3030.—Deterioration in stored raw sugars is prevented by inoculating them with torulae. VIII. *Ibid* 802-4, 856-8.—Methods for the inoculation of raw sugars with torulae as a preventative against deterioration. O. gives the advantages of the inoculation and concludes that the deterioration of raw sugars can be prevented by their protective inoculation with torulae. Sugars filmed with inoculated molasses are safer with a non-sucrose moisture ratio of 2 to 1 than are uninoculated sugars with a ratio of 3 to 1 as prescribed by the factor of safety. IX. *Ibid* 930 1.—The bacteriological control of raw-sugar factories, the estn. of microorganisms in raw juice and the detn. of special groups of organisms are described. The plate method of quant. analyses of bacteria is given. X. *Ibid* 946-7.—Bacteriol. control in the sugar factory and methods for detn. of microorganisms in sirups and sugars.

T. MARKOVITS

The use of chlorine in the refining of sugar. SHUICHIRO OCHI. *Trans. Am. Electrochem. Soc.* 49, (preprint)(1926).—It is shown that the chlorination process, in combination with the treatment by activated charcoal, is practical for sugar refining. The following has been found experimentally: The coeff. of the velocity of inversion of sugar in Cl water is about half the value in HCl of equiv. concn., at the outset of the inversion, and approaches the value of the equiv. HCl in the course of the inversion. The presence of molasses retards the velocity of inversion by Cl water or HCl. The bleaching action of Cl is not very effective with cane juice, but the chlorinated juice can be bleached easily by the subsequent treatment with activated charcoal. Cl has an efficient action in pptg. the suspended matters in cane juice, and this reaction occurs at a p_H value of 3.5 to 4.0 for the chlorinated juice. At the same time gums and pectins sep. out with the suspended matter. The bleaching action of Cl on the sirup of raw sugar is effective up to 80 to 90% of the original color depth. A bleaching beyond 95% is almost impossible in a short time. The sirup which contains free Cl even once neutralized, turns alk., and is colored dark in the course of the evapn. The use of activated charcoal subsequent to the chlorination, instead of chlorination only, saves a portion of the Cl, and a complete bleaching and neutralization can be obtained.

C. G. F.

• **Comparison of a vacuum quadruple- and a triple-pressure-effect evaporator for sugar juice.** F. STAUDINGER. *Z. Ver. deut. Zuckerind.* 1925, 367-82; cf. C. A. 19, 1787.

E. J. C.

Are special evaporator constructions necessary for pressure evaporation? H. CLAASSEN. *Centr. Zuckerind.* 34, 174-5(1926).—Such constructions as the Vimek Turek are supposed to prevent discoloration but C. holds that the time of contact of juice in them is no shorter than in a standard evaporator of the same size. There is no need for special constructions.

W. L. BADGER

Boiler plant instruments. R. B. WILLIAMS. *Facts about Sugar* 21, 280-1(1926). The installation and use of the CO₂ recorders and other instruments as steam flow meters, draft instruments, pressure indicators, coal meters, pyrometers and other indicating instruments in sugar houses.

T. MARKOVITS

A graphic chart for the pan floor. J. F. VOORWIJK. *Facts about Sugar* 21, 252-3(1925).—A scheme for solving graphically the problems involved in laying out the pan work of a boiler house giving the graphic detns. of the quantities of seeding grain, thick juice, and sirup taken into the boiling pan.

T. MARKOVITS

The Lawaczek viscometer as a control instrument for the dextrin industry. A. STIRNUS AND W. EKHard. *Z. Spiritusind.* 49, 40-1(1926).—A description of the

instrument and its use in detg. the dextrin content of solns. is given. The results obtained are expressed in abs. viscosity units.

Research work on dextrose and levulose. F. BATES. *Facts about Sugar* 21, 250-1 (1925).—Progress of the investigations of the Bur. of Standards on the problems of the manuf. of dextrose and levulose.

Our (Bulgarian) sugar beets. M. STEFANVOA. *Rev. inst. recherches agron. Bulgarie* 3, 539-52 (1925).—This is the report of a series of sugar analyses on 160 samples of beets from the crop of 1924 in Bulgaria. The heaviest section of the beet contains the most sugar, the light lower section of the root the smallest amt. of sugar.

Ways to dispose of sugar beet factory wastes. ANON. *Nation's Health* 7, 776 (1925); *Pub. Health Eng. Abstrs.* Dec. 26, 1925.—Results of expts. on the treatment of sugar beet factory wastes are given.

Nitrogenous substances in beet molasses. E. PARISI. *Ann. chim. applicata* 15, 555-68 (1925).—The only work of importance on the N compds. of beet molasses is that of Ravenna (*Ann. soc. agrar. prov. Bologna* 62, 157 (1912)) who detd. the total N, NH_3 , nitrates, protein, amides and amino acids. The present work includes detns. of N in various groups of compds. Such detns. are of importance because of the differing physiol. effects of the various groups of N compds. and their potential value in various ways. For this purpose a method was devised for sepg. the different groups. The % yields are based on the wt of original molasses. To molasses (100 g.) dild. with H_2O were added alternately in small portions 25% aq. $\text{Hg}(\text{OAc})_2$ and 10% aq. Na_2CO_3 until the white ppt. became yellowish red. The liquid (which should be neutral or alk.) was dild. with 5 vols. of EtOH , let stand 24 hrs., filtered and washed. The ppt. contained the amino and diamino acids, hexonic and purine bases; the filtrate and wash water the inorg. N, betaine, etc. The Hg ppt. when decompl. in H_2O with H_2S , filtered, the filtrate concd. to a blackish sirup and dild. (to 200 cc.) gave 1.19% total N and 0.40% amino N. The remaining liquid on treatment with aq. neutral $\text{Pb}(\text{OAc})_2$ and decompl. of the ppt with H_2S gave 0.041% N. H_2SO_4 was added to the filtrate from the Hg ppt until the soln was 5% concd., the soln filtered and to the filtrate (200 cc.) was added pure phosphotungstic acid (30 g.), the liquid warmed, let stand 48 hrs., filtered, the ppt. washed with a soln contg. H_2SO_4 (5 g.) and phosphotungstic acid (2.5 g.) in 100 cc. H_2O , intimately mixed with powd. $\text{Ba}(\text{OH})_2$, hot satd. aq. $\text{Ba}(\text{OH})_2$ (50 cc.) added, let stand, washed by decantation 5 times with satd. aq. $\text{Ba}(\text{OH})_2$, finally digested with hot aq. $\text{Ba}(\text{OH})_2$ and filtered. The alk. liquors were neutralized with H_2SO_4 , filtered, the excess H_2SO_4 was neutralized with $\text{Ba}(\text{OH})_2$, filtered, satd. with CO_2 and concd. *in vacuo* (to 200 cc.) The N pptd. by phosphotungstic acid was 0.20%. The remaining liquor was acidified with H_2SO_4 , evapd. (to 50-60 cc.), and hot satd. Ag_2SO_4 added until a drop of supernatant liquid gave no ppt. of Ag_2O with aq. $\text{Ba}(\text{OH})_2$. The ppt. could not be identified. The filtrate from the Ag-purine base ppt. was satd. with solid $\text{Ba}(\text{OH})_2$, filtered after 48 hrs. and both ppt. and filtrate were freed of $\text{Ba}(\text{OH})_2$ by H_2SO_4 and of Ag_2SO_4 by H_2S . In the liquids were found 0.07% total N in the lysine fraction and 0.09% total N in the arginine + histidine fraction. The filtrate and wash water from the phosphotungstic acid ppt. on addn. of $\text{Ba}(\text{OH})_2$ until alk., filtering, washing, satg. the filtrate with CO_2 and concg. *in vacuo* (to 100 cc.) gave 0.56% total N and 0.25% amino N in the monoamino-acid fraction. Acidification of the remaining soln. with H_2SO_4 pptd. tyrosine. The filtrate when neutralized with $\text{Ba}(\text{OH})_2$, let stand *in vacuo* over H_2SO_4 , the sirup extd. with cold, then with hot BuOH , evapd. *in vacuo* yielded leucine. The filtrate from the compds. pptd. by the Neuberg reagent freed of Hg by H_2S gave on concn. a thick clear yellow sirup, showing 1.02% total N, 0.36% basic N and traces of amino N. The soln. was acidified (Congo red) with HCl , concd. *in vacuo* to a cryst. paste and extd. with boiling EtOH (350 cc.). The part insol. in EtOH contained 0.15% total N. The EtOH ext. concd. *in vacuo*, hot satd. alc. HgCl_2 (200 cc.) added, let stand 1 week, filtered, the ppt. (9.5 g.) washed with EtOH and crystd. from boiling H_2O gave the compd. $\text{C}_{11}\text{H}_{17}\text{NO}_2 \cdot \text{HCl} \cdot \text{HgCl}_2$, m. 230°. More (21 g.) was recovered by concg. the mother liquors almost to dryness *in vacuo*. This compd. treated in H_2O with H_2S , filtered, evapd. to dryness *in vacuo* gave a cryst. compd. (1.7 g.), m. 245°; hydrochloride, m. 245°; chloroplatinate, needles m. 256°. The preceding compd. was proved by its picrate (m. 182°) and by vol. detn. of its HCl to be betaine, though the m. p. of the hydrochloride (*loc. cit.*) was different from that in the literature (227.8°) and the chloroplatinate was very stable in the air (previous work showing it unstable). Forty-six references to work bearing on the subject are included.

Annual report of the Gurdaspur Agricultural Station for the year ending 30th June

1924. M. S. ALI. *Rept. Operations Dept. Agr. Punjab* 1, Part 2, 1-45 (1925); cf. C. A. 19, 3169.—Analyses of 23 varieties of sugar cane (1) at the commencement of the crushing season—end of Nov. 1923, (2) at the middle of the crushing season—end of Dec. 1923, and (3) in the latter half of Jan. 1924 are tabulated. In general the highest percentages of total solids, total sugars and sucrose, and the lowest percentages of glucose were found at the last period of analysis. No definite relation existed between the amt. of juice and the time of sampling but this figure did not vary greatly. The performance of cane mills and sugar centrifugals with different varieties of cane is shown. Notes on gur-boiling furnaces and sugar making in the Gurdaspur district are given. Better protection against termites was obtained by treating the cane sets with crude-oil emulsion or by spraying the furrows with kerosene before putting in the sets than by treating the sets with kerosene or solignum. Black ants were partially controlled by applying KCN solns. to the nests. K. D. JACOB

Studies on plant colloids. XVI. Behavior of the starch components toward iodine and their protective colloid action. M. SAMEC. *Kolloidchem. Beihefte* 21, 55-77 (1925); cf. C. A. 18, 2975.—Within wide limits the I color of the starch substance is independent of the mean molecular size. It is not influenced by coupling either with a phosphoric-acid-containing substance, with phosphoric acid, or with silicic acid. The cations bound by the amylophosphoric acid have no effect on the I color. There is no simple relation between the I color and the protective colloid action for gold. The amt. of I_2 taken up by the aq. soln. of the starch differs with the various grain constituents. With the same KI concn. amylo compds. absorb more I_2 than erythro compds. The I_2 adsorption of amylo compds. rises with rise in KI concn. till a max. is reached and remains there. It is not essentially changed by age until the time when coagulation becomes visible. It is lowered by heating the soln. to 120° . Increasing dispersion increases the I_2 absorption of amylo compds and *vice versa*. Amylopectin absorbs less I_2 than amyloamyloses. The absorption capacity of the sol obtained from amylopectin is smaller the longer the time of heating required for the prepn. of the sol. The I_2 -combining power of the erythroamyloses decreases with increasing molecular sizes. It is noticeably increased by KI, the I_2 complex, in contrast to that of the amyloamyloses, not being pptd. by excess KI. In general, the sol starches and dextrin absorb the less I_2 the smaller the mol. size. The amyloamyloses show a better protective colloid action for gold than the erythroamyloses. In general, the protective colloid action increases with increasing dispersion. M. BEBER

The rate of solution of sucrose in nearly saturated solutions (KUCHARENKO, NACHMANOVICH) 2. Velocity of crystallization of sucrose from pure aqueous solutions at 60° (KUCHARENKO, NACHMANOVICH) 2. The determination of invert sugar in the presence of sucrose (OFNER) 7.

Maple sugar cakes. A. BROWN. U. S. 1,576,084, March 9. Maple sugar cakes are placed on wire screens, in a container, treated with maple sirup which has been boiled to a temp. of about $107-110^\circ$ and then cooled to about $50-53^\circ$, and the mass is allowed to set for about 12 hrs.

Cereal sugar in loaf or block form. R. E. DALY. U. S. 1,575,975, March 9. Granular dextrose sugar as it comes from a centrifuge, with a moisture content of 12-14%, is subjected to a gradually increasing pressure in a mold (with pressures of 200-2000 lbs. per sq. in.), the compressed material is forced out of the mold and is placed in a drying chamber where its moisture content is reduced to 8-10%, and the cut into blocks.

29—LEATHER AND GLUE

ALLEN ROGERS

Chemical-analytical standards in leather manufacture. A. M. GOLDENBERG. *Collegium* 1926, 10-21.—Data are given, showing normal analyses of the various liquors and the skin and leather at different stages of manuf. The values for finished sole and upper leather contg. 18% H_2O are: ash 1.5 and 0.8%, fat 1.2 and 14%, sol. solids 14 and 8%, hide substance 34-36 and 36-37%, fixed tan 30-31 and 22-23%, yield 281-290 and 270-278, resp. I. D. CLARK

A chemico-histological study of leather manufacture. I. The structure and

properties of freshly flayed steer skin. H. G. TURLBY. *J. Am. Leather Chem. Assoc.* **21**, 117-56(1926).—Descriptions of histological technic and of the microstructure of steer hide, illustrated by 21 photomicrographs. J. A. WILSON

Further studies of quinone tanning. A. W. THOMAS AND MARGARET W. KELLY. *Ind. Eng. Chem.* **18**, 383-5(1926); cf. *C. A.* **18**, 3123.—In neutral soln. NaCl retards and Na₂SO₄ accelerates quinone tanning. Extn. of quinone leather with C₂H₅OH removes some combined quinone, more from undried than from dried leathers and more as the initial tanning took place in more strongly alk. solns. Quinone leather combines with very little gallotannin. J. A. WILSON

Comparison of chrome and vegetable leather. A. DEFORGE. *Halle aux cuirs* **1926**, 37-50.—A review of recent American work on phys. properties H. B. M.

Use of sulfurous acid in the tannery. B. KOEHLER. *Gerber* **52**, 35-7(1926).—The use of liquid SO₂ is advocated for soaking, deliming, pickling and in 2-bath chrome tanning, as a substitute for more costly materials. H. B. MERRILL

Synthetic tanning material from phenols and cellulose. E. KÁRPÁTI. *Chem. Rund. Mitteleuropa u. Balkan* **2**, 71-2(1925).—Equal parts by wt. of crude cresol and concd. H₂SO₄ are heated for 1 hr. on the water bath, and a quantity of cellulose or material contg. it, up to 40% of the wt. of the cresol, is added in small portions to the product at 50-60°, the mixt. being thoroughly stirred. The product is diluted with water to d. 1.263-1.285, and neutralized. A soln. d 1.022 contg. 1% of acid yields a soft, plump leather. B. C. A.

Behavior of synthetic tanning materials toward hide substance. EDWARD WOLESENSKY. *Bur. Standards Tech. Paper* No. 309, 275-87(1926); cf. *C. A.* **20**, 1336.—Syntans obtained by first sulfonating an aromatic compd. and then condensing the sulfonic acid with an aldehyde combine rapidly with hide substance, but to a limited extent, and the limit of combination and the time required to reach this limit are but little affected by the concn. of the soln. This class is suitable only for light leathers unless used in conjunction with other filling materials. The concn. should not exceed 4% nor the time 10 days or the result may be injurious. When the order of sulfonation and condensation with aldehyde is reversed, in the manuf. of syntans, a second class is obtained which possesses much greater filling power, requires a longer time to reach the limit of combination with hide substance, and has a limit of combination which is dependent upon concn. This class can be used for making sole leather and other heavy leathers without the aid of other tanning materials. Concns. greater than 6% and time longer than 4 weeks should not be employed. The destructive action of syntans on hide substance varies from nothing to complete destruction, depending upon how they are made and used, but no relation has yet been found between this behavior and other characteristics of the syntans. J. A. WILSON

Report of the activities of the Naples branch of the royal experimental station for the industry of hides and tanning materials. V. CASABURI. *R. staz. sper. ind. pell. mat. concianti* **1924**, 39-43. R. C. FUSON

Report of the activities of the Turin branch of the royal experimental station for the industry of hides and tanning materials. G. BALDRACCO. *R. staz. sper. ind. pell. mat. concianti* **1926**, 3-24. R. C. FUSON

The fluorescence test. OTTO GERNGROSS AND GEORG SANDOR. *Collegium* **1926**, 1-10; cf. *C. A.* **20**, 517.—Exts., other than quebracho and tizerah, which show fluorescence are donga, reddish in neutral, orange in alk. soln., and pine bark, maletto bark and sulfite cellulose ext., blue violet in neutral and grass-green in alk. soln. On bating, filter paper, etc. (cellulose) an intense yellow fluorescence is shown by quebracho, tizerah and mimosa, a faint yellow by chestnut and hemlock, an intense violet by pine bark and maletto, a faint violet by oakwood, a faint white by mangrove, a faint red by donga, and none by sulfite cellulose ext. The fluorescent substance is absorbed reversibly by hide powder and irreversibly by cellulose. I. D. CLARKE

Gonakie [Acacia arabica]. PAUL AMMANN. *Cuir tech.* **15**, 122-6(1926).—Description and analysis of bark and fruit. H. B. MERRILL

Leather japanning. W. T. LATTEY. *J. Oil Colour Chem. Assoc.* **9**, No. 68, 45-9(1926).—A review of old and modern practice. R. J. MOORE

Dyeing kid skins [for gloves]. LEON CHARVAT. *Ganterie: Halle aux cuirs* **1926**, 57-9.—A description H. B. MERRILL

Experiments on the extraction of chromium from tanned leather by means of Seignette salt (sodium potassium tartrate). L. MASNER AND N. J. BIKESTOVJ. *Chem. Listy* **19**, 391-4(1925); cf. *C. A.* **19**, 3385.—Cr can be extd. from tanned leather scrap by means of any salt or acid that forms an inner complex with it. The extn.

is always incomplete. To obtain the best results a temp. of 80–100° is necessary, with about 1.5 g. of Seignette salt per g. of leather; with the same amt. of salt, the extn. is more nearly complete the more dil. the soln.

F. C. KRACKK

Polluted atmosphere a factor in the deterioration of bookbinding leather. F. P. VEITCH, R. W. FREY AND L. R. LEINBACH. *J. Am. Leather Chem. Assoc.* **21**, 156–76 (1926).—The parts of bindings exposed most to air, such as the back, were deteriorated to a much greater extent than parts less exposed, as the sides, and the parts most deteriorated showed the highest percent of H_2SO_4 . Since many of the bindings examd. were kept in rooms not lighted by gas, the accumulation of acid may be attributed to the atm. of the city at large.

J. A. WILSON

Use of the Cl gas process in the paper industry [tanning materials from waste liquor] (CONSIGLIO) **23**.

Drying gelatin. H. W. LUSHER. U. S. 1,575,348, March 2. Filtered air for use in the drying is divided into 2 portions, one of which is heated and the other of which is passed through an ozonizer. These sep. portions are then mixed before being brought into contact with the gelatin.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The chemistry of rubber. W. J. KELLY AND H. A. BRUSON. *J. Chem. Education* **3**, 253–66 (1926).—A review.

E. H.

The work of the Bureau of Standards on rubber. C. E. WATERS. *J. Chem. Education* **3**, 291–5 (1926).

E. H.

Elastic hysteresis and its importance in connection with the colloidal structure of rubber. HEINRICH FEUCHTER. *Kautschuk* Dec., 1925, 6–10; cf. Feuchter, *C. A.* **20**, 1149.—On stretching raw rubber to 1500% and then allowing it to recover at different temps., the permanent elongation decreases with increase of temp., the temp. permanent elongation curve being S-shaped and resembling the stress-strain curve of the same rubber. This similarity between the curves indicates that heat and mech. work have similar effects and suggests that the elasticity of rubber is a thermodynamic function of its structure. This in conjunction with the Thomson-Joule effect shows that in any rubber system, mech. work can to a certain extent be transformed into elastic strain or into heat and *vice versa*. The heat effect of this reversible colloid reaction is due to a change in the latent internal stresses, and the elasticity is a phys. result of a dynamic 2-phase system, involving changes from the colloidal to the cryst. state and *vice versa*. The relation between elasticity and temp. can also be shown by stretching raw rubber at different rates to rupture, in which case the ultimate elongation increases with the rate of stretching. This is an instance where there is both a dynamic and a thermal (reversible) reaction to the mech. force, the relative values of which depend upon the rate of stretching. This also involves a limiting state, *i. e.*, a max. anisotropy, where the rubber is characterized by a max. thermally reversible state of strain. The other limiting state is that of completely plasticized rubber, where there is a max. irreversible plastic displacement of particles and permanent elongation without internal stress. The anisotropic condition is essentially an assumption of a rigid mol. condition or crystn., and it is characterized by covalent forces and a reversible liberation of heat. The limiting state of plasticity is characterized by disintegration of a solid mol. structure or of crystallizates, which bears some close relation to chem. depolymerization, and is accompanied by a valence stress and an irreversible liberation of frictional heat. The progressive changes in elasticity represented by the hysteresis effect involve not only colloidal reactions, but a process analogous to changes in entropy, where the isotropic unplasticized rubber is transformed progressively through a max. to a min. elasticity.

C. C. DAVIS

The structure of elongated samples of rubber. E. A. HAUSER AND H. MARK. *Kautschuk* Dec. 1925, 10–1.—A preliminary note. Quant. measurements of the interference phenomena described by Katz (*C. A.* **19**, 2144, 2424, 2759) indicate that the position of the interference points is independent of the degree to which the rubber is elongated, but that their intensity increases approx. in proportion to the elongation.

The position of the amorphous ring is also independent of the elongation, but its intensity decreases with increase in elongation. It was also proved that the axes of the crystals formed on elongation rubber lie parallel to the direction of elongation (cf. Katz, C. A. 19, 2144). The interference points also resemble those caused by a true crystal structure in that the sines of their half angular distances from the primary ray increase in exact proportion to the wave length applied. The crystal lattice is apparently of rhombic tetragonal form with definite lateral dimensions. With increase in temp. the intensity of the interference points in elongated rubber varies directly with the ability of the rubber to recover its original length. When, however, the rubber is completely recovered the interference points disappear. If, on the contrary, the elongated rubber is cooled to -4° the intensity of the interference points remains unchanged. After sufficient mastication, rubber no longer exhibits interference phenomena on being elongated. C. C. DAVIS

The Pregl microanalytical determination of nitrogen in rubber (Dumas method). HANS WELLER. *Gummi-Ztg.* 40, 1198-9 (1926).—An accurate method for detg. the % N in rubber mixts. is of potential value in that it offers a means of controlling the uniformity with which an org. accelerator is incorporated in the mixt. Special precautions are necessary if the Pregl method (cf. Pregl, *Die quantitative organische Mikroanalyse*, Berlin) is used, because of the high C content. It is shown to be accurate to about 1% in detg. the N of nitrogenated org. compds. and, therefore, may be of use in testing the purity of an accelerator itself. In detg. the N of rubber mixts., 9-25 mg. of sample should be taken (corresponding to about 0.7-0.2% N). To avoid too rapid combustion and yet for the latter to be complete, the sample should be a uniform strip and should be buried in 0.5 its wt. of KClO_4 . Weighing should be to 0.001 mg. and combustion should extend over 25-35 min. In other respects the regular Pregl method may be followed. The method is accurate enough to show variations in the N content of rubber mixts. in which the org. accelerator is not uniformly incorporated. Thus inhomogeneous mixts. showed in different locations 0.50 and 0.57, 0.69 and 0.75, 1.56 and 1.62% N. Combustion without KClO_4 gave values less than 0.5 those with KClO_4 . C. C. DAVIS

Dental rubber. KATH. *India Rubber J.* 71, 312-3 (1926).—A description of the manuf. and use of dental cements and hard rubbers, with typical formulas of red and pink compds. C. C. DAVIS

Behavior of various tire stocks by various aging methods. W. W. VOGT. *Ind. Eng. Chem.* 17, 1197 (1925).—Correction by J. M. Bierer. See C. A. 19, 3172. H. G.

Further developments and applications of the Bierer-Davis oxygen aging test. J. M. BIERER AND C. C. DAVIS. *Ind. Eng. Chem.* 17, 1197 (1925).—Correction by J. M. Bierer. See C. A. 19, 3172. H. G.

Rubber fertilizer experiments at the experiment station, Petadeniya (HOLLAND) 15.

Measurements of Quality of Factice. Stamford, Conn. The Stamford Rubber Supply Co. 21 pp. Reviewed in *Rubber Age* 18, 358 (1926).

Hard rubber articles. J. F. JOHNSTON. U. S. 1,574,658, Feb. 23. A "blowing agent" is incorporated in rubber compns. for making molded articles, the articles are molded slightly smaller than final size and then heated in a vulcanizing mold of the desired final size and expanded to fit the mold.

"Age-resisting" rubber composition. E. W. FULLER. U. S. 1,573,928, Feb. 23. An alkali or alk. earth salt of α -nitroso- β -naphthol is added in the proportion of about 1%, or less to rubber compns. which may also contain ZnO , S and accelerators.

Vulcanizing rubber. N. A. SHEPARD AND S. KRALL. U. S. 1,576,072, March 9. A small proportion of a reaction product of an aldehyde ammonia with a mustard oil is used as an accelerator.

Vulcanized rubber. H. A. MORTON. U. S. 1,574,676, Feb. 23. A mixt. of rubber, S and accelerator is calendered into a sheet, an activator is applied to the surface of the sheet, it is then rolled on itself and cured.

Accelerators for rubber vulcanization. P. M. PAULSON. U. S. 1,575,806, March 9. Mono-*o*-tolylguanidine or other compds. of the general formula $\text{R-N(R')-C(NH)-NH}_2$ are used as accelerators.

Accelerators for rubber vulcanization. C. S. WILLIAMS. U. S. 1,575,884, March 9. Monophenylguanidine or other compds. of the general formula $R-N(H)-C(NH)-NH_2$ are used as accelerators.

Manufacture of rubber-coated weftless-cord fabric. A. GESSNER, JR. U. S. 1,573,390, Feb. 16. Mech. features.

Apparatus for making balls or other hollow rubber articles. F. T. ROBERTS. U. S. 1,574,113, Feb. 23.

Forming balls or other hollow rubber articles. F. T. ROBERTS. U. S. 1,574,060, Feb. 23. Mech. features.

CHEMICAL ABSTRACTS

Vol. 20.

MAY 20, 1926

No. 10

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Little things in chemical apparatus? A. E. *Tech. Ind. Schweiz. Chem.-Ztg* 1925, 181-9, 203-12(1925).—A discussion, with 32 cuts, of the right and wrong positions of welded seams, shapes of enameled app., location of gages, thermometers, etc., faulty designs of enameled mixers, steam-jacketed vessels and vacuum pans, liquid seals, pumps, etc. J. H. MOORE

New porcelain apparatus for the laboratory. KURT THURMANN. *Oesterr. Chem.-Ztg* 29, 28-9(1926).—A *Buchner funnel* fitted with a jacket, cast integral with the funnel, serves for hot or cold filtrations. Dark blue or white *glazed porcelain plates* find use in testing dry colors by rubbing in oil. A *crucible* for ashing oils and fats is barrel-shaped to avoid loss by spattering. An *evap. dish* has the upper edge constricted to minimize creeping. An *insert for desiccators* has 6 sectors, of triangular shape, constricted at the base, which afford support for crucibles of any size. T. S. CARSWELL

Mechanically recording differential dilatometer. P. CHEVENARD. *Rev. métal.* 23, 92-9(1926).—The Chevenard differential dilatometer (*Rev. métal.* 14, 610(1917); cf. *C. A.* 11, 2743), originally designed for recording photographically, has been modified to give a mechanically produced record. The new instrument is described, and a no. of curves obtained with it are given and discussed. A. PAPINEAU-COUTURE

Rotary air (and vacuum) pump for laboratory work. ANON. *Engineering* 120, 816-7(1925).—3 figs. DONALD W. MACARDLE

A laboratory pump for the circulation of gases. W. FRANCIS. *Fuel in Science & Practice* 5, 39-40(1926).—The action depends upon the motion imparted to a glass piston in a glass tube by a solenoid acting on a soft iron tube enclosed within the piston. The pump is in a vertical position, and when the circuit is made and broken by a pendulum the piston alternately rises by attraction to the solenoid and then falls. During the upward motion a valve at the top closes and a lower valve opens, allowing gas to be drawn in below the piston. When the latter falls, the valves reverse and the gas displaced by the piston flows through the system. The app. is illustrated and various precautions and refinements are described. C. C. DAVIS

A new spiral gas-washing bottle. L. H. MILLIGAN. *Science* 63, 363-4(1926). E. H.

Storage of small quantities of gas at low pressures. J. J. MANLEY. *Proc. Phys. Soc. London* 38, 129-31(1926).—An elaborate *app.* for storing rare or highly purified gases to avoid contamination of air. The gas is delivered to the reservoir by a Sprengel pump, and restored to the exptl. plant by means of barometric traps. A. W. F.

A simple method of preparing ultrafilters. E. MÜLLER. *Kolloid-Z.* 37, 237-8(1925).—The app. consists of 2 glass vessels, *A* and *B*. *A* is fitted with a ground-glass cover and a 2-hole stopper through the opening near the top and designed to hold an easily removable glass framework holding 8 filters. *B* is an ordinary bottle of suitable size fitted with a 2-hole stopper. *A* and *B* are connected with glass tubing, 2 one-way and one 3-way cock all joined together with pressure tubing so that the soln. of colloidion or gelatin can be interchanged between *A* and *B* by alternating air pressure with a vacuum produced with a H_2O pump. H. M. McLAUGHLIN

The temperature of vapor from a solution. K. SCHREBER. *Chem. App.* 13, 13-4, 44-5, 53-5(1926); 3 cuts.—The app. is described by which results were obtained in substantial agreement with those of Möbius. Cf. *C. A.* 18, 1601; 19, 1518, 1806. J. H. MOORE

An improved form of Schiff's nitrometer. R. B. FORSTER. *Chemistry & Industry* 45, 55(1926).—In the usual type the tube is of uniform bore and is graduated from 0 to 100 cc. by $\frac{1}{2}$ cc. The lower part is useless since the N should pass through a considerable height of KOH. Also the graduations on the part used are not fine enough. The instrument is improved by making the lower portion of somewhat greater bore and

ungraduated, while the upper part is graduated from 0 to 25 cc. by 1/10 cc., this without increasing the height of the app. M. A. YOUTZ

The installation of electrical temperature-measuring instruments. MAX MOELLER. *Siemens Z.* 6, 65-72(1926).—Mechanical and elec. measurements are made technically more accurately than those of temp., chiefly because of difficulties involved in installing instruments for the latter purpose. Errors due to cond. of materials of construction, heat transference from gas to tube of thermometer, the protective tube, depth of insertion into heated space, temp. difference between gas and the tube wall, radiation losses, etc., are discussed. Actual detns. on temps. of steam in pipes and of air (still or in quiet motion) under thermostatic control were conducted, and the conclusion was reached that with a correct installation, proper choice of materials of construction and dimensions of the instruments and their jackets, accurate measurements are possible. Special attention is demanded by the cond. of the protective tube and its connections, wall thickness and resistance to corrosion. W. C. EBAUGH

Improvements in mechanical apparatus relating to the Butters filter plant. A. H. DAVIDSON. *J. Chem. Met. Soc. S. Africa* 25, 214-23(1925). H. C. PARISH

Mammoth agitators. STEEN. *Chem.-Ztg.* 50, 18-20(1926).—Mammoth agitators employ the principle of a particle falling a long distance through a liquid contained in a cylinder of comparatively small area. The cylinder may be closed to prevent escape of volatile products, and the operation may be maintained with mixts. under high pressure. The cylinders or towers are often built in series with automatic feed from one to the other, thus decreasing the total height required. Air-lift pumps move the materials with economy and ease. The distance through which a particle is allowed to fall is regulated by the time required for its soln., disintegration, etc. Operations requiring counter-currents are easily conducted. Illustrations are given for agitators working at 40 atms. for converting H into hydrocarbons, the operation requiring 3.5 hrs. in comparison with 17 hrs. by the old method. Other forms of app. for treatment with CO₂, Cl, HCl, soln. of salts, prepn. of cement slurry, etc., are described. W. C. E.

Cut-off device for leaky valves. M. B. *Apparateurbau* 38, 52-3(1926); 1 cut.

J. H. MOORE

Pressure apparatus for conveying slimy products. M. BERGER. *Apparateurbau* 38, 50-1(1926); 1 cut.—A pump using compressed air. J. H. MOORE

A compressed air de-oiler. CONSTANTIN REDZICH. *Apparateurbau* 38, 51-2(1926). 3 cuts.—The Buhring separator. J. H. MOORE

The Jung automatic feeder (as patented by Dallwitz-Wegner) and its use in saccharin manufacture. E. BELANI. *Chem.-Ztg.* 49, 877-9(1925).—The Jung automatic feeder consists of a plunger working in a sleeve, with a discharge pipe at the top. The downward thrust of the plunger is controlled by clockwork, or by a thermometer, so that a definite feed of liquid can be obtained. It finds use in feeding SO₃HCl and PhMe in the production of MeC₆H₄SO₃Cl, and in feeding KMnO₄ in the oxidation of MeC₆H₄SO₂NH₂. A complete description of the technical saccharin process is given. T. S. CARSWELL

Two new monochromators with preliminary separation (double monochromators for the visible and ultra-violet regions. CARL LEISS. *Z. Physik* 34, 103-8(1925). H. C. UREY

Practical form of photo-electric photometer. C. H. SHARP AND C. KINSLEY. *Trans. Illum. Eng. Soc.*, Feb., 1926; *Elec. World* 87, 823(1926).—One of the difficulties in the way of using a photo-elec. cell in a photometer is that no form has yet been produced which has the same color sensitivity curve as that of the eye. However, by the use of suitable color filters comparisons can be made of lights differing in color within certain ranges. A second difficulty is the fact that the current set up by a cell is extremely small—on the order of 0.02 microampere with 100 volts on the cell and 1 foot candle illumination—and its resistance is extremely high, e. g., 5000 megohms in the case mentioned. This suggests the use of a triode amplifier if the indicating instrument is not to be excessively sensitive. In both the earlier and later forms of the photometer, now fully described, a single cell was used in order to avoid the effect of a possible dissimilarity. The cell was exposed alternately to one and the other of the light sources to be compared—that is, by a balance method, as in visual photometry. The principle of the final form of the instrument is shown in a diagram. C. G. F.

IHERING, ALBRECHT: Maschinenkunde für Chemiker. 3rd ed. revised. Leipzig: Joh. Ambr. Barth. 348 pp. R. M. 16.

Acetylene generator. J. L. BRILLANTES. U. S. 1,579,856, April 6.

- Acetylene generator.** I. M. HACKNEY. U. S. 1,578,725, March 30.
- Laboratory apparatus for generating hydrogen, carbon dioxide or other gases.** D. L. WARRICK. U. S. 1,578,942, March 30.
- Apparatus for carbonating water or other liquids.** A. M. HORN and W. T. FARROW. U. S. 1,580,085, April 6.
- Apparatus for treating solutions containing metal-bearing liquids with precipitating gas or for treating other liquids with gases.** W. E. GREENAWALT. U. S. 1,579,355, April 6.
- Apparatus for automatic analysis of flue gases, etc.** L. YOUNG and G. W. RUGGLES. U. S. 1,578,697, March 30.
- Apparatus for determining temperatures by carbon dioxide content of combustion gases.** F. D. POTTER. U. S. 1,577,853, March 23.
- Washing and charging filters for air.** J. H. FEDELER. U. S. 1,577,703, March 23.
- The top and bottom of filter material such as that used for filtering air are alternately subjected to a spray of H_2O and a spray of viscous material.
- Air-cooled water still.** E. C. BALLMAN. U. S. 1,577,675, March 23.
- Apparatus for solidifying carbon dioxide.** T. B. SLATE. Brit. 237,681, May 23, 1924.
- X-ray target.** H. C. RENTSCHLER. U. S. 1,579,779, April 6. A target for X-ray tubes has a focal spot of Th, U or similar material of high atomic wt. surrounded by a material such as Cr or Ti of low atomic wt. and having a m. p. above 1500. The contiguous surfaces of the 2 materials are sintered together.
- Permeable membranes for dialyzing.** J. M. LOONEY. U. S. 1,576,523, March 16.
- Nitrocellulose is mixed with alc. and dissolved by further addition of ether, a H_2O -sol ester such as EtOAc is added to the soln. and it is spread and the solvent removed to form a dialyzing membrane.
- Apparatus for feeding regulated quantities of chemicals to steam boilers or other apparatus.** J. L. HUGHES. U. S. 1,576,911, March 16.
- Electric discharge tubes.** EDISON SWAN ELECTRIC CO., LTD. Brit. 237,923, Aug. 1, 1924. Disintegration of the cathode and noises in speech reproduction due to gas ionization are diminished by including very small quantities of electropositive gas such as H (partly occluded in the electrodes and walls of the tube). Brit. 237,924 specifies tubes contg. Na, K, Rb, Ca, Ba or Sr to absorb gas and facilitate formation of electrons and positive metal ions. The metals are deposited in the form of mirrors.
- Absorption apparatus adapted for vapor recovery.** C. I. VORESS, R. W. SKROOG and V. C. CANTER. U. S. 1,577,200, March 16.
- Heat exchange apparatus adapted for heating viscous oils.** R. C. JONES and J. PRICE. U. S. 1,578,830, March 30.
- Magnetic separator for removing articles of iron and steel from loose flowing materials.** R. GREAVES. U. S. 1,579,354, April 6.
- Radon tube or implant of intense color and ready visibility.** C. H. VIOL. U. S. 1,574,456, Feb. 23.

GEORGE L. CLARK AND BRIAN MEAD

- Emil Warburg, his eightieth birthday.** E. GRUNEISEN. *Naturwissenschaften* 14, 203-7 (1926).—A short biography with portrait. **Emil Warburg and technical science.** H. SCHERING. *Ibid.* 208-11.—Biographical. B. J. C. VAN DER HOEVEN
- Chemistry and pure science.** B. B. BOLTWOOD. *Science* 63, 345-7 (1926). E. H.

The importance to chemical theory of a knowledge of the physical properties of substances. F. G. KEYES. *Nucleus* 3, No. 7, 5-9 (1926). E. H.

Daltonian and non-Daltonian compounds. A. GLAZUNOV. *Chem. Listy* 19, 339-45 (1925).—G. defines a chem. individual as a result of chem. action such that it has chem. and phys. properties peculiar to itself alone; these properties bear no definite relation to the properties of the constituents of the individual. Chemical individuals can be classified into (1) those that have singular points on property-composition curves, and (2) those that show a smooth variation of a given property with composition. Under (1) may be classified all ordinary chem. compds., they follow the law of simple and multiple proportions, etc. As example, consider the m. p. of mixts. of Na and Cl. At the composition corresponding to NaCl there is a singular point, the m. p. of NaCl. It is not exactly clear what substances G. intends to classify under (2), but the idea may

be illustrated by the system Fe + S. In this system FeS dissolves up to 4% Fe in the solid state. This solid soln. is a distinctly homogeneous phase of variable compn. G. calls individuals of the first kind *dallomides*, those of the second kind *bertholides*.

F. C. KRACKH

The compression and decomposition of nitric oxide. E. BRINER, H. BIEDERMANN AND A. ROTHEN. *J. chim. phys.* 23, 157-75(1926).—See *C. A.* 20, 685. R. L. D.

An X-ray examination of *i*-erythritol. W. G. BURGERS. *Phil. Mag.* [7] 1, 289-303(1926).—Erythritol $(CH_2(OH)CH(OH)CH(OH)CH_2OH)$ has two asym. C atoms, although linked with the same groups in both cases. The compd. is thus comparable with tartaric acid. The object of the investigation is to det. by means of X-rays whether a difference in spatial arrangement of the group about the asym. C atoms could be detected. The symmetry is tetragonal-bipyramidal. The body-centered unit cell contains 8 mols. The crystal mol. must have two-fold symmetry, either a center or a two-fold axis. The X-ray evidence leads to the conclusion that the crystal mol. is centrosym. The crystallographic configuration, therefore, confirms that already assigned by stereochemistry.

S. C. LIND

The structure of thin films. VII. Critical evaporation phenomena at low compressions. N. K. ADAM AND G. JESSOP. *Proc. Roy. Soc. (London)* 110A, 423-41 (1926); cf. *C. A.* 19, 759.—By means of a new app., accurate measurements of the surface pressure of monomol. films have been made at room temp. down to 0.01 dyne/cm. At areas greater than 5000 A. U. per mol., the pressures exerted by films of insol fatty substances tend to a value within 25% of that given by the equation $Fa = RT$, where F = force in dynes/cm., a = area per mol. in sq. cm., and R = gas const. The exptl difficulties of measurement at these areas are so great that the divergences from the theoretical values are within exptl. error. Between 100 and 5000 sq. A. U. the pressure-area isothermals closely resemble those for liquid and vapor in 3 dimensions. With longer chains in the mol. there is a horizontal "vapor pressure" region, ending on the one hand in an imperfect gaseous film; on the other hand, in either the condensed or expanded type of film. When the chains are shorter, a condition which corresponds to a higher temp., the "vapor pressure" region disappears, and the films are above their "critical pt." Expanded films are analogous to liquids, not vapors, and there is considerable cohesion between the mols. in them. The heats of two-dimensional evapn. from expanded to gaseous films are of the same order of magnitude as the heats of spreading, from bulk to a condensed film, on a water surface. The evidence, although not complete, indicates loss of orientation in expanded films.

J. H. PERRY

The modifications of amorphous carbon. F. J. NELLENSTEYN. *Chem. Weekblad* 23, 134-5(1926); cf. *C. A.* 19, 3188; 20, 774.—A reply to Honigs criticism (*C. A.* 20, 1132).

B. J. C. VAN DER HOEVEN

The five alkali metals under high pressure. P. W. BRIDGMAN. *Phys. Rev.* 27, 68-86(1926).—New data are given for the effect of high pressure on the m. p. of Rb and Cs. The results of a comparative study of the effect of pressure on the m. p. elec. cond. and vols. of the five alkali metals are given and discussed. Numerically the compressibility is of the order of magnitude of that of a perfect gas under high internal pressure with the electron as the gas unit.

D. C. BARDWELL

Theories of passivity (of metals). H. GERDING AND A. KARSSSEN. *Z. Elektrochem* 31, 135-43(1925).—A crit. survey of the theories of the passivity of metals. The theories are classified under the headings: purely phys., purely chem. and physico-chem. That due to Smits (*C. A.* 9, 3015) by an extension of his theory of allotropy is received the most favorably, since it explains in addn. the phenomena of polarization and overvoltage.

B. C. A

Method of producing monocrystalline metals. I. V. OBREIMOV AND L. V. SHUBNIKOV. *Trans. Phys. Rech. Lab. Leningrad* 100, 21-4(1925).—A modification of Tamman's method; single crystals of Sn, Bi, Pb, Cd, Zn, Sb, Al, Mg and Cu in various sizes from 1 to 30 mm. in diam. and up to 30 cm. long have been obtained. The essential point in the new method is to draw the test tube into a capillary end where a small crystal of the metal is placed as the center of crystn. The cooling of the molten metal in the test tube is started from the capillary end and is allowed to proceed gradually upwards.

R. PIROOMOV

The question of existence of critical density. K. SHAPOSHNIKOV. *J. Russ Phys.-Chem. Soc., Phys. Part* 56, 581-92(1924).—S. favors the hypothesis that the disappearance of meniscus at the crit. temp. is due not to the d. of the liquid and vapor becoming equal, but rather to the process of complete mixing between liquid and vapor which takes place when liquid and vapor have different d. A series of computed tables is given to substantiate this viewpoint.

R. PIROOMOV

Measurement of high vacuum. B. N. KLAYRFELD. *J. Russ. Phys.-Chem. Soc., Phys. Part 57*, 129-32(1925).—An elec. discharge in a capillary tube can be used for the measurement of high vacuum, the method being simple but not very accurate (within 50%). For this purpose 2 electrodes are soldered into the capillary tube of the McLeod gage and the pressure at which the discharge between the 2 electrodes takes place, is detd. by another gage. This happens over the range of pressure in the capillary from 0.05 to 0.005 mm. Hg, depending on the size of the capillary. Knowing the ratio to which the air in the gage is compressed, the original pressure of the gas can be detd. In this way it was found possible to measure the pressure down to 5×10^{-8} mm. Hg.

R. PIROOMOV

Production of high vacuum by means of Langmuir's pumps and its application to distillation of mercury. V. I. ROMANOFF. *J. Russ. Phys.-Chem. Soc., Phys. Part 57*, 124-8(1925).—I. Two Langmuir pumps placed in series and connected to a vessel of 3-5 l. capacity (serving for preëxhaustion) by means of 2 Hg taps, one after the first and the other after the second pump, reduce the use of the oil pumps for preëxhaustion only for starting purposes, since after being started the Langmuir pumps will keep up the necessary preëxhaustion for a very long time. II. The app. for distg. Hg uses the Langmuir pump and operates on the principle described above. It is automatic and continuous. With an energy source of 200-250 w. the production of the app. reaches 0.5-0.7 kg. Hg per hr.

R. PIROOMOV

The production and measurement of high vacuums. G. W. C. KAYE. *Engineering* 121, 240-1(1926).—An abstract of a historical address. The gases absorbed and adsorbed by the materials of the evacuating app. are gradually given off again and deterioration of the vacuum results. The highest measured vacuums obtainable are of order of 10^{-8} mm. (10^{-11} atm.).

W. H. BOYNTON

The determination of the vapor tensions of mercury, cadmium and zinc by a modified manometric method. C. H. M. JENKINS. *Proc. Roy. Soc. (London)* 110A, 456-63(1926).—In the method used, the substance under investigation is used as the liquid in the manometer which is used to indicate a balance between the vapor pressure of the substance and an externally applied pressure of N_2 . The measurement is made statically, the vapor being in contact with a free surface of the liquid. The substance is, therefore, not superheated at the time of measurement. The manometer consists of a tube, $\frac{1}{8}$ in. internal diam. and 18 in. long, bent into a 60° V. In the closed end of this V is sealed a thermocouple sheath, projecting into the tube $\frac{3}{4}$ in. The straight part of the tube is so arranged and heated that different portions of it act as a reflux condenser, an evaporator and a condenser for the metallic vapor. The furnace is mounted in a frame which permits of its rotation about two axes at right angles—circumferentially in the end plates and in a vertical plane about the trunnions. The temps. of the metal in the manometer was detd. by a Pt-Pt,Rh couple. The accuracy of the app. was checked by the detn. of the vapor pressures of Hg. The b. p. of Hg was detd. to be 357° . The accuracy of the pressure readings is approx 2 mm. and that of the temp. about 1° at 600° . A few of the data for each metal are given here: Cd: 503° , 15 mm.; 583° , 60; 645° , 159.5; 698° , 322; 756° , 672; 771° , 799; 804° , 1131; 836° , 1535. Zn: 629.5° , 19 mm.; 709° , 68; 778.5° , 183; 822° , 313; 880° , 589; 904° , 749; 918.5° , 853; 946° , 1104; 982.5° , 1517. The b. ps. of Cd and Zn were detd. to be 767° and 906° , resp. J. H. P.

Absorption of gases by a liquid drop. W. G. WHITMAN, LOUIS LONG, JR., AND H. Y. WANG. *Ind. Eng. Chem.* 18, 363-7(1926).—Absorption rates have been detd. for a drop of H_2O , falling freely through a gas for a distance of 52 cm. Results are given on CO_2 and NH_3 absorption and on humidification of air. The rate coeffs. are higher than those reported for absorption through flat liquid surfaces, from rising gas bubbles, or in wetted wall columns although the ratio of liquid film to gas film coeffs. is about the same.

L. A. PRIDGEON

The air-bubble viscometer. GUY BARR. *Phil. Mag.* 1, 395-405(1926).—The effects of length of bubble and diam. of tube have been examd. and the rates of rise detd. for several oils of known viscosity and surface tension, for water and for glycerol in different tubes. A dimensional analysis of the problem has been made involving certain assumptions which seem to be capable of verification, in any particular case from the appearance of the bubble. Above a certain limit the length of the bubble is without appreciable effect on the rate of rise. For bubbles rising "slowly" in a given tube, i. e., at such a rate that not more than one thickened annulus of liquid appears between the bubble and the walls toward the rear end of the bubble, it has been found that the rate of rise is inversely proportional to the kinematic viscosity, provided that the surface tension is const. An approx. detn. has been made of the form of the function of r/a upon which, in addition to the viscosity, the rate of rise depends. In certain

conditions, *e. g.*, when light oils are examd: in a tube of such a diam. as to give a convenient rate of rise, the rate may vary about 14 times as fast as the diam. and 6 times as fast as the surface tension, but these effects become very much less pronounced when viscous liquids are used in wide tubes. The air-bubble viscometer may be used with confidence for the approx. comparison of viscosities of materials of the same class. A simple modification is suggested which enables a check to be made on the assumed constancy of surface tension.

S. C. LIND

A new optical phenomenon shown by biaxial crystals. S. R. SAVUR. *Phil. Mag.* **50**, 1282-95(1925).—S. takes up the theory of the phenomenon observed by Raman and Tamma, namely, that a biaxial crystal plate suitably cut and oriented produces a real image of a bright object. New expts. confirming and illustrating the phenomenon under different conditions are described, and a mathematical treatment of the theory is presented. The predictions of the theory are given an exptl. test with satisfactory agreement.

S. C. LIND

The physical properties of binary liquid mixtures in the vicinity of the critical temperature of miscibility. N. PERRAKIS. *J. chim. phys.* **22**, 280-310(1925).—Over the whole range of immiscibility, the vapor pressure of binary liquid mixts. varies very little. The m. p. is hard to det. on account of viscosity and supercooling. Detns. on PhOH-EtOH (I), *o*-cresol-EtOH (II) and Ph₂O-EtOH (III) systems show a flat curve of temp. vs. concn. (III), indicating poor miscibility; and a steep curve (I and II), where the miscibility is greater. The systems C₆H₆ plus Me (IV) Et (V) iso-Pr (VI) and *n*-Bu (VII) ales show an increasing miscibility with increasing mol. wt. of the ale. A theoretical discussion leads P. to the conclusion that slightly below the crit temp. (a) the variation of surface tension is substantially zero; (b) the surface tensions of the 2 liquid phases simultaneously in equil. with the air phase are equal. Detns. of the sp heats and heat of mixing of systems (II), (III), (V) and (VII) show that (a) the sp heats observed are greater than those calcd. from the constituents by additivity, (b) the differences are too great to be neglected in the calcn. of the heats of mixing. The curves of ds vs. concn. in systems (II) to (VII) also show a rectilinear portion for mixts. which are near the crit. state (III and IV). The results of the addn. of H₂O to systems III to VII (g H₂O necessary to produce the sepn. in 2 phases) are somewhat difficult to interpret. This is probably due to the fact that this apparently independent variable changes at the same time the miscibility of the 2 phases and the soly of H₂O in one of them. In general for all phys. properties, the proximity of the crit. state is indicated in the diagram "property vs. concn." by a substantially straight line, which may or may not be horizontal.

G. CALINGAERT

The permeability of nickel to hydrogen; influence of pressure. VICTOR LOMBARDI. *Compt. rend* **182**, 463-4(1926); cf. *C. A.* **17**, 3434.—Temp. was maintained const. and the gas was measured by the increase of pressure in the chamber receiving it. The permeability of Ni to H is an exponential function of the temp., and varies proportionally to the square root of the gas pressure. It is not inversely proportional to the thickness of a Ni sheet, but diminishes very rapidly with the first increase in thickness beyond a fraction of a mm., and more slowly with further increase in thickness. Curves show that the logarithm of the permeability decreases linearly as the thickness increases.

G. F. C.

The spreading of solids on water surfaces. N. K. ADAM AND G. JESSOP. *Proc. Rpy. Soc. (London)* **110A**, 441-3(1926).—A. and J. have continued Cary and Ridal's observations (*C. A.* **20**, 133) on the spreading of myristic acid on H₂O at very low comp. pressures. A small pressure, that of the "gaseous" state of the films, is set up within a few seconds after the crystal touches the surface, and the "two-dimensional vapor pressure" very soon afterwards.

J. H. PERRY

The adhesion of mercury in highly evacuated capillaries. CURT HAGEN. *Physik. Z.* **27**, 47-57(1926).—At pressures below 10⁻³ mm. Hg, the Hg in the capillary of a MacLeod gage tends to stick; the length of the sticking Hg thread is a characteristic function of the pressure. The following influences were noticeable: Sharp edges at the top of the capillary prevent sticking, previous heating of the glass diminishes it, the hanging curve flattens at higher temps.; if Fe is used as part of the capillary it does not occur, Cu or brass capillaries show it to a smaller degree, Wood's metal instead of Hg does not show it. No influence on the phenomenon is found to be caused by gas liberated from the glass walls, by sealing wax or by filling the tube with H. The sticking capacity of a standardized capillary may be used for measurement of very low pressures.

B. J. C. VAN DER HOEVEN

The solubility of hydrogen in tin and aluminum at high temperatures. L. I. BIRCUMSHAW. *Phil. Mag.* [7] **1**, 510-22(1926).—It appears to be practically impossible

to sat. a metal with a gas by keeping the unstirred metal at const. temp. in contact with the gas, because of the long time necessary for the attainment of equil. The statement of Sieverts that H_2 is insol. in Sn and Al has not been verified. A small but definite soly. of H_2 in Sn at 800° has been measured, and evidence of a considerable soly. of H_2 in Al just above its m. p. has been found. The rate of soln. of H_2 in Sn is detd. by the rate of diffusion of gas through the bulk of the metal. Very long times appear to be necessary to remove all the gas from a metal by heating *in vacuo*; suggestions are made to explain this fact.

S. C. LIND

Adsorption of ethylene and hydrogen by zinc oxide, iron oxide, nickel and copper. W. A. LAZIER and HOMER ADKINS. *J. Phys. Chem.* 30, 353-8 (1926) — Measurements of the adsorption of H and C_2H_4 at 22° and 74 mm. by catalysts were made in the usual const.-pressure adsorption app. The catalysts were of Cu, Ni, Fe_2O_3 , and ZnO, made by several different methods. The vol. of the gas adsorbed was measured by reference to the vol. of N_2 required to fill the adsorption app. under comparable conditions. The catalytic activity of the catalysts was detd. by measuring the decrease in gas vol. after exposing the catalyst to equimol. mixts. of H and C_2H_4 . The results of the adsorption and catalytic activity measurements indicate that there is a qual. agreement between the 2 manifestations of chem. activity, but there is apparently no quant. relationship between total adsorption and catalytic activity.

R. L. DODGE

The mechanism of the adsorption of ions. R. AUDUBERT and M. QUINTIN. *J. chim. phys.* 23, 176-96 (1926).—See *C. A.* 19, 2153

R. L. DODGE

Adsorption. II. The adsorption by a coconut charcoal of saturated vapors of some pure liquid. F. G. TRYHORN and W. F. WYATT. *Trans. Faraday Soc.* 1926, (advance proof)—The rate of adsorption of the vapors of 14 liquids by a purified coconut charcoal was detd. at 20° . The initial rate is proportional to the vapor pressure of the liquid and inversely proportional to the square root of its mol. wt. For 11 of the liquids, the velocity of adsorption time curves show a discontinuity, which is attributed to the sudden formation of a liquid surface in the charcoal. **III. Stages in the adsorption by a coconut charcoal from vapor mixtures of alcohol and benzene, and of acetone and benzene.** *Ibid.*—The adsorption curves of these binary mixts. consist of 3 parts. In the first, both components are adsorbed in a const. ratio, which is practically that in which they exist in the vapor phase. When condensation occurs in the charcoal, the second stage occurs, during which the liquid phase adjusts itself to be in equil. with the main bulk of liquid by displacement of alc. or acetone by benzene. In the third stage the liquid is isothermally distd. into the intergranular spaces of the charcoal.

ARTHUR GROLLMAN

Determination of the diameter of pore and pore number in filter stones. HERMANN RUOSS. *Chem.-Ztg.* 50, 83-4 (1926) — Two methods are described for the detn. of the diam. of pores in filter plates: (1) hydrostatic detn. of the diam. of the capillary const. of a liquid, and (2) hydrodynamic detn. of the diam. of the capillary by means of the viscosity const. of a liquid. The latter method has been regarded as the most reliable also in consideration of unsym. pores. R. has detd. the av. diam. of pores and speed of filtration, which also is a measure for the permeability, in Schuler filter plates.

D. THUESEN

Colloidal electrolytes. A. LOTTERMOSER. *Z. angew. Chem.* 39, 347-53 (1926).—See *C. A.* 20, 532.

E. J. C.

The preparation of colloidal gold. C. F. BEHRENS. *Naval Med. Bull.*, Wash., D. C., 21, 191-2 (1924); *Abstracts Bact.* 9, 216 — The cause of unsatisfactory colloidal Au has been traced in almost every instance to the K_2CO_3 soln. No carbonate soln. over 24 hrs. old should be used.

H. G.

Action of proteins on gold sols. W. REINDERS. *Chem. Weekblad* 22, 481-4 (1925) — The variations in the protective effect of proteins in sols. of different degrees of acidity and alkyl. have been followed by measurements of the Au numbers and the migration velocities for different values of pH and different concns. of protein. The results are in accordance with the known amphoteric character of the proteins.

B. C. A.

The change with time of the double refraction of streaming sols containing non-spherical particles. I. The behavior of vanadium pentoxide sols. H. FREUNDLICH and H. DANNENBERG. *Z. physik. Chem.* 119, 87-95 (1926) — The rapidity with which the double refraction of a V_2O_5 sol increases with the age of the sol has been studied quantitatively. H_3PO_4 and electrolytes like NaCl have no effect, while H_2AsO_4 decreases the rate of this so-called aging of the sol. Coagulation does not account for the observations since the coagulating action of H_2AsO_4 is negligible in comparison with that of NaCl. It is possible, however, that the aging of the sol is due to the disappearance of the smaller V_2O_5 particles with consequent increase in size of the larger ones, a process

which will be greatly influenced by the H_2AsO_4 on account of the well-known fact that foreign material is adsorbed on the surface of crystals with consequent decrease in rate of crystn. The relation between rate of aging and concn. of H_2AsO_4 can be calcd. approx. from the adsorption isotherm. The aging follows an equation of the second order, as Marc has shown to be true for the process of crystn. The high thermal coeff. also supports the crystn. theory. II. The behavior of benzopurpurin sols. *Ibid* 96-103.—The increase in double refraction, or aging, of a benzopurpurin sol is caused by coagulation, contrary to the case of the V_2O_5 sol. A similarity exists, however, between the two processes of aging, in that the final result in both cases is the formation of fiber-shaped secondary particles arranged parallel to each other in the streaming sols.

PER K. FRÖLICH

Hygroscopicity of gels of ferric oxide, alumina and silica. B. AARNIO. *Geol. Komm. Finland Geotekn. Meddel.* 1920 [25], 12 pp.— $Fe(OH)_3$ pptd. by NH_3 retains 10% of water at 100°, 1.5% at 200° and 1% at 300°, and the corresponding hygroscopicities of the products are 34%, 42% and 29.6%, resp. At 700° no water is retained, and the oxide is no longer hygroscopic. The hygroscopicity of $Al(OH)_3$, similarly pptd. is 24% after heating at 100°, 45% at 400°, 44% at 800°, 17% at 1000° and 0.53% at 1200°, at which temp. the oxide still retains 0.2% of water. The hygroscopicity of silica gel is 41% at 100°, 56% at 200°, 45% at 400°, 50% at 500°, 0.62% at 1000° and 0.5% at 1100°. Its water is completely removed by heating at 1000°.

B. C. A.

The elasticity of jellies of cellulose acetate in relation to their physical structure and chemical equilibria. H. J. POOLE. *Trans. Faraday Soc.* 1926 (advance proof, Feb. 22); cf. C. A. 19, 2153.—The elasticity of jellies of cellulose acetate in various concns. of benzyl alc. and H_2O followed approx. the square of the concn., indicating the rigid phase to result from a dynamic solvation equil. between the cellulose acetate and solvent. The load-strain curves bent continuously towards the load axis, indicating the existence of a rigid fibrillary structure in the jelly. Heating or cooling does not cause a permanent deformation of temporarily deformed specimens. Equil. in elastic properties is only slowly regained after cooling or warming. The attraction of the cellulose acetate mols. is considered to be of a local character and to extend to a distance less than the size of the mols. themselves. The coeff. of inner resistance is proposed to denote the force normal to a face which is required to produce unit velocity of "creep" in a unit cube of jelly in the absence of all elastic controlling forces. Its values run parallel with the viscosity of the parent sols. The effect of variations in its concn. showed benzyl alc. as a solvent for cellulose acetate to be deficient in OH groups. Its partial replacement by H_2O causes a decrease in elasticity and an increase in solvation. Replacement by xylene gives the reversed effects.

ARTHUR GROLLMAN

Temperature of swelling of starch granules. W. ARZICHOVSKI. *Bull. acad. sci. russie* 1918 [6], 349-68.—The swelling of starch granules was studied microscopically, a statistical method being used. Swelling begins at 55°; at 67.5° it is practically complete. The mean temp. of complete swelling of individual granules is $60.97 \pm 0.10^\circ$. The distribution about this mean value only follows Gauss' law of error as a first approximation. The frequency curve is asymmetrical, but there is no indication of the occurrence of 2 kinds of granules.

B. C. A.

Colloid chemistry of humus and peat. WO. OSTWALD AND A. STEINER. *Kolloid-chem. Beihefte* 21, 97-170 (1925).—Humus prepn. made from peat was purified by dialysis; diffusion, ultrafiltration, electrophoresis, surface tension, sedimentation ability and viscosity were studied. Particular attention was paid to viscosity, which showed itself particularly fitted for the study of flocculation. The humus sols prepd. are neg. charged, moderately hydrated systems behaving in many respects, particularly in flocculation, like neg. hydroxide sols such as MoO_4 and V_2O_5 . Flocculation with salts gives essentially the same sort of values. The same flocculation relations are also found in peat suspensions. Flocculation is characterized by either increase in viscosity or increase in filtration time. Increase in viscosity depends on formation of "larger secondary particles" just as does increase in filtration time. These can further combine to aggregates of higher order as is shown by the great influence of previous mech. treatment on the viscosity of flocculated humus sols or of peat suspensions. Addn. of small amts. of alkali causes reprecipitation of humus preps. After flocculation by iron or other heavy metals, org. bases, e. g., pyridine, must be used as peptizing agents. Free Cl_2 (in Cl_2 water) is an especially effective flocculating agent. Neutral, strongly acid, and alk. (particularly) humus preps. show the same surface tension as water, which is remarkable since all preps. foam very readily. The addn. of flocculating agents (particularly Cl_2) in the drying of peat enables one to obtain harder and denser dried prod-

ucts if the drying process is slowed down temporarily at the beginning. Quant. values are given in tables and figures. M. BEBER

The separation of crystalloids from one another by dialysis. LOUIS KAHLBERG. *Phil. Mag.* [7] 1, 385-94(1926).—K. describes expts. in selective dialysis. For non-aqueous solns. a rubber membrane, the ordinary dental rubber dam, was employed by stretching it over a thistle tube. Pyridine proved to be the most suitable solvent; water gave no action; alc. but little; hydrocarbons softened the rubber. Esters, ketones, aldehydes and nitriles proved unsuitable. Substances which are sol. in water were non-dialyzable when dissolved in pyridine, while substances not sol. in water but sol. in org. solvents like hydrocarbons when dissolved in pyridine were dialyzed. Consequently, substances in these two classes could be sepd. by dialyzing the pyridine soln., for example, S from sugar, naphthalene from sugar, S from AgNO_3 , camphor from sugar, etc. For aq. solns. copper ferrocyanide membrane allowed urea to pass but retarded sugar. Lanolin (wool fat) when absorbed in fine China silk or in parchment paper produced a good membrane. Lanolin in collodion membranes was not practical, but by dipping silk into CHCl_3 soln. of lanolin gave good membrane. Substances readily dialyzable through this membrane are boric acid, borax, NaCl , urea; less so Na_2SO_4 ; not at all cane sugar, dextrose, lactose; very difficult egg albumin, litmus and fuchsin. Not only could crystalloids be sepd. from colloids but certain crystalloids could be sepd. from each other. The addn. of a third substance may aid the sepn. It was proved that cholesterol is the effective constituent of lanolin and since cholesterol is contained in all living animal cells, it is suggested that delicate films of cholesterol give to those cells their selective osmotic properties. S. C. LIND

Studies on the coagulation of clay. RENÉ GALLAY. *Kolloidchem. Beihefte* 21, 431-89(1926).—The coagulation of clay has been studied experimentally in an effort to correlate previous data on coagulation phenomena and to subject opposing theories to a critical test. The investigation involves the effect on coagulation of the following variables: degree of dispersion, base interchange, nature of clay, and nature of the coagulating electrolyte. It is found that in a polydisperse system, as exemplified by a clay suspension, the coarser particles tend to facilitate coagulation of the finer ones. The min. concn. of electrolyte necessary for flocculation increases with decreasing particle size. A coarse suspension is more affected by an increase in electrolyte concn. than a fine suspension, a phenomenon which accounts for the step-wise change in viscosity during the coagulation process. The coarser particles may have settled completely even before the finer ones have commenced to agglomerate. By mutual interference particles of different size fall at the same rate, and hence the individual layers which may be formed during the coagulation do not consist of uniformly sized particles. When the clay carries univalent bases, salts of bivalent metals lose part of their efficiency as coagulating agents on account of base interchange, which also accounts for the increase in the pptg. action of K and Na salts for clays carrying bases of bivalent metals. Clay treated with CaCl_2 is more sensitive to a univalent salt than clay treated with NH_4 , K or Na salts. The coagulating action of uni- and bivalent cations increases in the series Li, Na, NH_4 , K, Rb, Cs and Mg, Ca, Ba. The viscosity of the coagulum, and consequently the degree of hydration of the flocculated particles, decreases with decreasing degree of hydration of the adsorbed particles and with increasing degree of hydration of the ions in the external liquid. Na-treated clay gives a more viscous flocculation than clays subjected to pre-treatment with K or NH_4 salts. It is concluded that the hydration theory does account for the effect of certain salts (as introduced, for instance, by fertilizers) on the phys. structure of the soil. PER K. FRÖLICH

Physical chemical properties of solutions of germanium dioxide (and arsenic trioxide). W. A. ROTH AND O. SCHWARTZ. *Ber.* 56, 338-48(1926).— GeO_2 gives neg. charged colloidal solns., as well as weakly acid true solns. On the latter, kept from contact with glass whenever possible, the following properties were detd.: Sp. gr., refraction, cond., f. p. lowering. The cond. of solns. satd. in the cold gives a dissocn. const. of 1.2×10^{-7} ; solns. satd. hot do not give a good const. The at. refraction is calcd. as 8.9, which value is compared with those of the other elements of the same group. The highest concns. obtained are $1/25$ N at 18° , $1/50$ at 0° ; the mol. f. p. lowering, 1.83 to 1.85, shows normal behavior. As_2O_3 on the other hand, is still assocd. to a certain extent in dil. solns. G. CALINGAERT

The growth and solution of crystals. G. FRIEDEL. *Bull. soc. franç. mineral.* 48, 12-69(1925); cf. *C. A.* 18, 1407; 19, 773.—A math. formulation of the phys. laws of growth and soln. Growth or soln. of a surface is detd. by the pos. or neg. character of a single equation in which the surface vector is a const. and the concn. and rate of diffusion are variables. The rate of diffusion is a function of the character of the soln.

(*per se*), and of the crystal, because the angle between 2 surfaces detcs. the "diffusion region" of each surface.

C. B. SLAWSON

The theory of concentrated solutions. II. JEAN LINARD. *Bull. soc. chim. Belg.* **34**, 363-98(1925); cf. *C. A.* **16**, 3021.—A no. of f. p. curves for binary org. mixts. have been studied in order to det. the applicability of Mortimer's modified form (*C. A.* **17**, 2216) of LeChatelier's equation for calcg. each branch of such curves, *viz.*, $\ln C = (Qf/R) - (1/T - 1/T')$, where C is the concn. of the substance which crystallizes out on the branch of the curve in question (mol. %), Q is the mol. heat of fusion of the substance (cal.), R is the gas const. (2.0), T the abs. fusion temp. of the solvent, T' the temp. at which crystn. of the given soln. begins, and f is a correction factor for non-ideal solns. which may be calcd. from π , the relative internal pressure of the component in question referred to $C_{10}H_8$ (as tabulated by Mortimer, *loc. cit.*). The systems $PhNO_2-PhNH_2$, $C_6H_6-CCl_4$, and $PhNO_2-CCl_4$ are complex in consequence of the formation of addn. compds. and do not give curves agreeing with those calcd. by the formula. The systems $PhNH_2$ -cyclohexane and $PhNO_2$ -cyclohexane, forming or tending to form systems contg. 2 liquid phases, likewise do not conform. Systems which present no such complications and to which the formula applies with considerable accuracy, are $C_6H_6-PhNH_2$, $C_{10}H_8$ -cyclohexane, $PhNO_2-C_6H_6$, *m*- $MeC_6H_4NH_2-PhNH_2$, $PhNH_2-CHCl_3$ and *o*- $MeC_6H_4Cl-PhCl$. Other systems described are *p*- $MeC_6H_4NH_2$ -cyclohexane, $CH_2BrCH_2Br-PhCl$, $CH_2BrCH_2Br-CCl_4$, $PhNH_2-C_6H_6$ and *p*- $MeC_6H_4NH_2-C_6H_6$. Curves and data are given for all systems above noted. Although, in general, systems in which the equation does not hold are those in which f as calcd. from π has a value of 1.8-2.2 this cannot be taken as a general criterion of applicability of the equation, since exceptions have been noted. The formula does, however, present a useful method of detg. Q for a given substance by detg. its f. p. curves with several substances of known Q and T , it being obvious from the form of the cooling curves obtained if the system is a complex one (because of addn. compds., etc.), to which the equation does not apply.

W. B. PLUMMER

Condition of ferric salts in solution. N. A. TANANAEV. *Mitt. weiss. techn. Arb. Rep.* (Russia) **13**, 74-5(1924).—Ferric salt solns. contain a small part of the Fe as colloidal $Fe(OH)_3$ owing to hydrolysis, and this part is not detd. in the iodometric method of detg. ferric salts; the difference between the gravimetric and iodometric results is, therefore, a measure of the colloidal $Fe(OH)_3$ present.

B. C. A.

The law of neutral salt action in concentrated solutions. I. The neutral salt action in the acid hydrolysis of cyanamide. G. GRUBE AND G. SCHMID. *Z. physik. Chem.* **119**, 19-45(1926).—The hydrolysis of cyanamide to urea is catalyzed by HNO_3 with marked increase, up to 36 times, by neutral nitrates. Designating the velocity const. in salt-free soln. of a given acidity by v_0 , and that in soln. of the same acidity and salt concn. c by v , $[1/c] \log(v/v_0) = \tau$, in which τ is a const. depending on the salt. The velocity in salt-free soln. increases more rapidly than the HNO_3 concn., and this extra catalytic action of the acid follows the same equation as the neutral salts. The same relation holds for numerous cases in the literature for which $c \geq 1$, with some exceptions at lower concns.; illustrations are sugar inversion, $EtOAc$ saponification, potential of H_2 , quinhydrone and Cu electrodes.

B. H. CARROLL

Some considerations of the reaction-constant equation, and a simple method of determining the end point. R. C. SMITH. *Phil. Mag.* [7] **1**, 496-9(1926).—A method is given of calcg. the end point (time T_∞) of first-order reactions from any 2 measurements having the relation $2t_n = t_{n+1}$, that is, the second interval (from t_0) is twice as long as the first. The expression is $T = T_n^2/(2T_n - t_{n+1})$. Its use and limitations are discussed. A similar method may be applied to second-order reactions but the expression is much more complicated.

S. C. LIND

The calculation of velocity constants. GERHARD SCHMID. *Z. physik. Chem.* **119**, 8-18(1926).—The velocity const., k , of a reaction may be calcd. from ν observations of c and t by the following formula, in which $l = \log c$ for a monomol reaction, or $-1/c^{n-1}$ for a reaction of the n th order. $k = \{l_1 + l_2 + l_3 + \dots + l_{\nu/2} - (l_{(\nu/2+1)} + l_{(\nu/2+2)} + \dots + l_\nu) / [l_{(\nu/2+1)} + l_{(\nu/2+2)} + \dots + l_\nu - (l_1 + l_2 + \dots + l_{\nu/2})]\}$. S. proves that this is equal in accuracy to the method of least squares, and free from the errors of ordinary methods of calcn. of k ; it is adapted to the weighting of observations, but in this case the numerator and denominator must be divided into groups of equal wt. instead of equal no.

B. H. CARROLL

Critical potentials of hydrogen in the presence of catalytic nickel and copper. J. H. WOLFENDEN. *Proc. Roy. Soc. (London)* **110A**, 464-76(1926).—The following criticisms of Gauger's work (*C. A.* **13**, 1226) are made: (1) The specimen curve of G's paper is of unusual form and shows certain breaks, which are not supported by the work of other investigators of the crit. potentials of mol. or at. H, and hence may be fictitious.

(2) The total correction for initial electron velocity and contact potentials seem to have been applied wrongly. (3) The magnitude of this correction seems to be incorrect for 2 reasons: (a) The method of application assumes that the relative sensitivities of the app. for detecting radiation and primary electrons are the same, and (b) the overall contact potential corrected for, is that between the filament (W) and the plate (Pt) connected to the electrometer, whereas the contact potential involved in the main expts. is that between the filament and the target of catalytic Ni. (4) A final uncertainty arises as to the origin of the radiation measured. None of G's expts. detd. whether the effects observed originated in the body of the gas or at the catalyst surface. A modified app. is described in which measurements of ionization from H_2 in the presence of catalytic Ni, plain Ni and catalytic Cu were made. By comparison of these results with those obtained when mol. H_2 was the principal source of ionization, it is concluded that substantial quantities of at H_2 are present at the metal surface in each of the above cases. It is shown that a similarity exists between the effect upon the form of the ionization curve of the presence of the catalyst metal and that of an incandescent grid. The results are of significance in connection with the mechanism of catalytic hydrogenation.

J H PERRY

Remark on the theory of two-phase catalyzers. H CASSEL. *Naturwissenschaften* **14**, 103-4 (1926).—According to Langmuir this type of catalysis takes place at those points where 3 phases meet. In order to account for the reaction speed, however, it is necessary to assume with Volmer (*C. A.* **19**, 1982) that the mols. of gas adsorbed on the gas-solid interface, have a 2-dimensional heat motion, or that of 2 reacting gaseous components each is preferentially adsorbed on one of the two phases of the solid catalyst.

B. J. C. VAN DER HOEVEN

Regions of reaction. I. W. P. JORISSEN. *Chem. Weekblad* **23**, 79-82; *Chem. News* **132**, 149-52 (1926).—The reaction regions of systems of 3 components are presented graphically, by means of triangles, each angle representing 100% of the corresponding component. By suitably varying the conditions a mixt. may be arrived at in which the reaction no more progresses. The instances treated are mainly the explosion regions of: (I) Mixts. of 3 gases, of which one acts only as a diluent, or where any of 2 gases may react with the third: O, H, N; air, CO, N, H, C_2H_4 , O; H, C_2H_4 , air; CO-air mixts. with CCl_4 , $CHCl_3$, CH_2Cl_2 , CH_3Cl , H, NH_3 , O, H, NH_3 , air, CH_4 -air with non-combustible gases such as CCl_4 , C_2HCl_3 , $C_2H_2Cl_2$, C_2Cl_4 , $C_2H_2Cl_4$, C_2HCl_5 . One % of CCl_4 is sufficient to prevent explosion. Practically important cases in which one gas is endothermic are: C_2H_2 , acetone, air, C_2H_2 -saturated hydrocarbons, CS_2 , NO, N; CS_2 , NO, CO_2 ; H, O, S. (II) Gas-solid systems. CH_4 , air, coal dust, and the extinction of mine gas explosions by an inert gas or by mineral dust. (III) Liquid-liquid, and liquid-solid systems (various explosives). (IV) Solid-solid systems (fuses and thermite compds.).

MARY JACOBSEN

Immobile groups of atoms with strong specific external fields as the cause of catalytic activity. F. H. CONSTABLE. *Proc. Roy. Soc. (London)* **110A**, 283-301 (1926).—Surfaces obtained by electrodeposition, reduction of ammoniacal solns. of Cu, and by hammering and polishing were inactive as catalysts. Surfaces produced by the rapid condensation of Cu vapor, or by violent agitation of the atoms in an inactive surface at 820° , or by the thermal decompn. of Cu salts in a stream of inert gas, were active. The inactive forms presented a bright metallic appearance and the surface under the microscope was quite smooth, the surface activity per unit area being probably less than $1/5000$ that of reduced Cu. It has been shown that the activities of preps. of Cu from cuprous and cupric oxides are almost equal, in opposition to Palmer's theory (*C. A.* **14**, 3183) that the inactivity of electrolytic Cu was due to its being composed of cupric Cu. Adkin's theory (*C. A.* **16**, 4116) that Cu atoms when discharged at the electrode will be closely packed, and that there will be a weak field of force at the surface, is confirmed. The metal produced by the decompn. of NH_3 at 820° was deeply pitted. Its activity was const. for some hours, yet on reexamin. the metallic appearance was almost entirely regained. Microscopic examn. showed that the larger pits had been filled up but that the smaller irregularities on the surface had persisted. This is direct evidence that the surface activity is due to the irregular arrangement of the surface atoms. The structure of the surface is fixed at the instant of formation. Catalysts obtained by chem. reaction all showed nearly the same activity and the same temp. coeff. of activity. Variations among the different catalysts were found in the heat of adsorption of H_2 from 9600 to 20,000 cal. per g. mol. which shows that the effective mean field strengths vary considerably with the state of the surface. When active Cu is formed by chem. change, the Cu atoms are suddenly liberated and crystd., there are still remaining atom groups which are frozen in a strained state. The fixation of such

groups of atoms fixes sp. fields of force sufficiently intense to cause such internal strain in the adsorbed mols. that chem. reaction occurs at a measurable rate. The evidence obtained by C. supports the theory of Pease and Taylor that catalytic activity is due to highly unsatd. atoms in the surface, but C. prefers to attribute activity to the electrostatic and magnetic fields of force on the strained atom groups which make up the centers of the surface activity. The rapid condensation of Cu from vapor freezes highly strained arrangements of atoms in the surface and is, therefore, active. As the kinetic energy of the atoms of the catalyst increases with temp., the active configurations slowly change back to the cryst. form, which shows that annealing reduces catalytic activity. The essential feature necessary for the production of active Cu is the sudden liberation of free Cu atoms under conditions in which the kinetic energy of the atoms of the structure is insufficient to cause collapse of the active centers. Thus, methods of prepn. of Cu under the same phys. conditions should give Cu with the same surface activity and showing the same temp. coeff. of activity. This is proven by the prepn. of Cu from Cu formate and valerate. There is apparently some limit to the distortion of the adsorbed mol. produced by the centers of activity of one particular substance. Since the surface fields vary with the nature as well as the arrangement of the surface atoms, the nature and magnitude of the mol. distortion will vary with the chem. nature and the physical state of the surface. This explains the specific action of catalysts. Very small amts. of added material could cause wide variation in the nature and distribution of the activity centers which tentatively account for promoter action. When the reactants form intermediate compds. with the catalyst, the form of the surface is destroyed and any theory of centers of activity as given by C. is invalid. J. H. P.

The influence of minute traces of water on solubility equilibrium. II. ERNST COHEN AND SABURO MIYAKE. *Z. physik. Chem.* 119, 247-53(1926).—See C. A. 20, 1164. E. J. C.

Equilibria in systems with phases which are separated by a semipermeable membrane. XII. Systems in which a substance other than water diffuses. F. A. H. SCHREINEMAKERS. *Verslag Akad. Wetenschappen Amsterdam* 34, 886-95(1925); cf. C. A. 20, 1020.—The series of papers is continued, the "membrane phase rule" applied.

B. J. C. VAN DER HOEVEN

Valency problems. E. MÜLLER. *Z. Elektrochem.* 31, 143-57(1925).—M. develops a scheme for the graphic representation of chem. compds. by an extension of the theory that atoms have a tendency to form an outer shell having the "inert gas number" of electrons, namely, 8. The no. of electrons in the outer shell is denoted by strokes attached to the at. symbol in a manner similar to the representation of ordinary valency. To simplify the formulas, a thick stroke may be used to denote 2 electrons and a thin stroke 1 electron. Compds. may be either "heteropolar," in which electrons are given up by 1 component to "satisfy" the outer shell of the other, resulting in 2 oppositely charged ions, or may be "homopolar," in which the electrons are shared by the components. Application of the scheme serves to throw light on problems presented by the following: aliphatic and aromatic double bonds; the benzene ring and other single ring systems; naphthalene and other condensed ring systems; conjugated double bonds; bivalent C; quadrivalent O; vinyl alc.; nitro and *pseudo*-nitro compds.; ClO₂; the oxides of N; NH₄ salts; triphenylmethyl; the change from propyl to isopropyl alc.; the formation of alc. and CO₂ from sucrose; the hydration of ions; polymerization. Reference is made to the views of Knorr (C. A. 17, 3264). B. C. A.

Action of sulfur monochloride on silica. P. P. BUDNIKOV AND E. A. SHILOV. *Mitt. wiss.-tech. Arb. Rep.* (Russia) 13, 64-5(1924).—By the action of 40 g. of S₂Cl₂ on 5 g. of silica at 1000°, 40% of the silica was converted into SiCl₄ in 1 hr. B. C. A.

Constitution of the system sodium stearate-water. A. VON BUZÁGH. *Chem. Rund. Mitteleuropa u. Balkan* 2, 52-4, 72-3(1925).—With falling temp., the elec. cond. of Na stearate solns. approaches a limiting value at a rate inversely proportional to the concn. It would appear that water in soap gels is only mechanically bound, since the compn. of the liquid phase expressed from gels several weeks old is never the same, and the quantity of stearate dissolved diminishes with the increase of solid phase. Moreover, the cond. of the ultrafiltrate is lower than that of the original system, a behavior attributed to adsorption of stearate mols. by stearic acid set free by hydrolysis. Such conclusions are in agreement with the fact that the basicity of the system increases with the proportion of solid phase. B. C. A.

Thermal analysis of the system boron trifluoride-hydrogen sulfide. A. F. O. GERMANN AND H. S. BOOTH. *J. Phys. Chem.* 30, 369-77(1926).—BF₃ was prepd. from B₂O₃, H₂SO₄ and CaF₂ and was purified by fractional distn. H₂S was similarly purified

and the f. ps. of a series of BF_3 , H_2S mixts. were measured. The compositions of the mixts. were detd. by measuring the vols. of BF_3 and H_2S gas admitted to the f. p. app. Temps. were measured by a liquid-propane thermometer with an accuracy of 1° or 2° . The f. p. curve is compared with the existing curves for H_2S -HI; H_2S -HBr; H_2S -HCl; H_2S - CH_3OH and H_2S - $(\text{CH}_3)_2\text{O}$ mixts. The system H_2S - BF_3 presents a max. at -137° , with a soln. contg. equimol. quantities of the 2 gases, showing the existence of the compd. $\text{BF}_3 \cdot \text{H}_2\text{S}$. Judging from the flatness of the curve at the max., the compd. $\text{BF}_3 \cdot \text{H}_2\text{S}$ is considerably dissocd., so that there should be little difficulty in sepg. H_2S as an impurity from BF_3 by fractional distn. The curve also shows 2 eutectics, one at -148° with 22 mol.-% H_2S and the other at -140° with 53 mol.-% H_2S . The form of the curve at -99° with $87\frac{1}{2}$ mol.-% H_2S indicates that this is the transition point of a cryst. addn. compd., whose formula seems to be $\text{BF}_3 \cdot 7\text{H}_2\text{S}$. The compds. are discussed in the light of the Lewis valence theory.

R. L. DODGE

The accurate measurement of heats of vaporization of liquids. J. H. MATHEWS. *J. Am. Chem. Soc.* 48, 562-76 (1926).—The heats of vaporization of 59 liquids were measured in a new elec. heated evaporator. This evaporator was suspended in the vapor to be evapd., the loss of weight being measured directly. The following data were obtained, the first value being the boiling temp., the second the heat of vaporization in cal. per g. PhH 80.20, 94.35; PhEt 135.17, 81.08; C_7H_{16} 97.23, 76.35; Pr_2CHMe 117.20, 70.86; cyclohexane 80.00, 85.62; methylcyclohexane 99.90, 76.92; cyclohexene 81.60, 88.70; PhMe 109.66, 86.50; $o\text{-C}_6\text{H}_4\text{Me}_2$ 141.41, 82.89; $m\text{-C}_6\text{H}_4\text{Me}_2$ 138.30, 81.85; $p\text{-C}_6\text{H}_4\text{Me}_2$ 137.12, 81.03; CH_2Cl_2 40.48, 78.74; $\text{C}_2\text{H}_4\text{Cl}_2$ 82.21, 77.34; $\text{C}_2\text{H}_4\text{Br}_2$ 130.80, 46.24; EtI 71.16, 45.62; BuI 129.50, 45.93; $\text{ClHC} \cdot \text{CCl}_2$ 85.69, 57.24; $\text{Cl}_2\text{C} \cdot \text{CCl}_2$ 120.69, 50.04; $\text{HCCl}_2\text{HCCl}_2$ 145.03, 55.02; $\text{H}_2\text{CClCH}_2\text{OH}$ 126.55, 122.97; PhCl 130.56, 77.61; PhBr 154.79, 57.63; $o\text{-C}_6\text{H}_4\text{ClMe}$ 158.07, 72.61; $p\text{-C}_6\text{H}_4\text{ClMe}$ 160.38, 73.14; CHCl_3 60.14, 58.80; CCl_4 75.40, 46.55; CS_2 45.29, 84.07; CH_3NO_2 99.90, 134.94; $\text{C}_6\text{H}_5\text{N}$ 114.13, 107.38; MeOH 63.81, 263.31; EtOH 77.42, 201.88; Me_2CHOH 81.25, 159.23; BuOH 116.78, 141.31; $\text{Me}_2\text{CHCH}_2\text{OH}$ 106.84, 138.25; EtCH(OH) CH_3 98.13, 134.41; $\text{Me}_2\text{CHCH}_2\text{CH}_2\text{OH}$ 130.17, 119.84; PhCH $_2$ OH 204.25, 111.58; Me_2CO 56.00, 122.09; MeCOEt 78.20, 105.95; furfural 160.55, 107.51; Et $_2\text{O}$ 33.99, 86.08; EtCOOH 139.30, 98.83; HCO_2Me 31.32, 112.38; HCO_2Et 53.33, 97.21; HCO_2Pr 80.01, 88.15; HCO_2Bu 105.12, 86.76; $\text{HCO}_2\text{CH}_2\text{CHMe}_2$ 97.03, 78.51; AcOMe 56.34, 98.11; AcOEt 76.00, 87.63; AcOPr 100.42, 80.29; AcOCH $_2$ CHMe $_2$ 115.47, 73.76; EtCO $_2$ Me 79.00, 87.59; EtCO $_2$ Et 97.64, 80.07; EtCO $_2$ Pr 120.62, 73.18; EtCO $_2$ Bu 144.87, 71.75; MeCHCO $_2$ Et 91.05, 78.15; PrCO $_2$ Et 118.90, 74.72; $\text{Me}_2\text{CHCO}_2\text{Et}$ 109.22, 72.08; AcOCH $_2$ CH $_2$ Cl 141.50, 80.84. Accuracy claimed ± 0.1 cal. No special precautions are mentioned to avoid spray. Vapor pressure and sp. vols. of Me_2CO , PhH C_7H_{16} were detd. Heats of vaporization calcd. from these data agree with those directly detd. ± 1.0 cal.

F. R. B.

The heats of combustion of homologous and isomeric dicarboxylic acids and their anhydrides. H. HARTMAN. *Tech. Hoogeschool Delft, Dissertation* 1925, 126 pp.—Methods of prepn. of satd. normal aliphatic dicarboxylic acids and of alkyl-substituted succinic acids are discussed. Dissocn. const. of Et- and some Ph-substituted succinic acids were detd. at 25° . On adaptation of the $\text{NCCl}_2\text{CO}_2\text{Et}$ synthesis of Bone and Sprankling to $\text{Et}_2\text{CBrCO}_2\text{Et}$ the product is $\text{HO}_2\text{CCH}_2\text{CHMeCHEtCO}_2\text{H}$ instead of the expected $\text{HO}_2\text{CCH}_2\text{C(Et)}_2\text{CO}_2\text{H}$. The latter, as well as $\text{HO}_2\text{CCH(Et)C(Et)}_2\text{CO}_2\text{H}$, may be prepd. by the method of Higson and Thorpe (*C. A.* 1, 175). *Trichylsuccinic acid*, m. 118° was prepd. by sapon. of ethyl α,β -dicyano- α,β,β -triethylpropionate, b_p 184° , b_p 138° , obtained by ethylation of Et $_2\text{C(CN)CH(CN)CO}_2\text{Et}$. Heats of combustion were detd. for (1) acids of the oxalic series from C_2 to C_{13} , (2) Me- Et- and Ph-substituted succinic acids, (3) anhydrides of the latter. In acids of the oxalic series, 2 thermally homologous series are distinguishable, viz., acids with even or uneven no. of C atoms. The explanation of this alternation probably lies in the differences in crystal structure. Oxalic and malonic acids occupy anomalous positions with respect to their homologs. Normal dicarboxylic acids have a lower heat of combustion than their isomeric alkylsuccinic acids. Of the latter, the *anti* acid has the highest, and the *sym.* acid the lowest heat of combustion. In the dialkylsuccinic anhydrides the heat of combustion is greater when the alkyl groups are in closer proximity. All of the heats of combustion, except that of racemic $(\text{CH}_3\text{EtCO}_2\text{H})_2$, follow Stohmann's rule, according to which the acid with the greatest dissociation const. has also the greatest heat of combustion. Bethmann's views furnish no satisfactory explanation of the relation between constitution and dissociation const. in the alkylsuccinic acids. The heat of hydration of $(\text{CH}_3\text{CO})_2\text{O}$ decreases regularly with successive introduction of Me groups. Those of the Me and the *unsym.* di-Et derivs. show little change, that of the *sym.* di-Me deriv. is 4 cal. lower, of the tri-Me deriv. 6 cal., and of the tetra-Me deriv. 9 cal. lower. The

liquid Et derivs. follow the same order as the solid Me derivs. The solid $(\text{C}_6\text{Et}_3\text{CO})_2\text{O}$ has practically the same heat of hydration as the tetra-Me deriv. For the mono-Ph anhydride the heat of hydration is 12 cal., for the racemic $(\text{CHPhCO})_2\text{O}$, 8 cal..

A. W. DOX

Heats of formation of quinonechloroimines and quinonedichlorodiimines. (MLLE.) S. BALSZKOVSKA. *Bull. Inter. Acad. Polonaise* 9-10A, 409-28(1924).—In an extension of previous work by Swientoslawski (C. A. 5, 1414) the thermal values of the processes whereby the hydrochlorides of aromatic diamines and aminophenols react in aq. soln with Cl water or bleaching powder to ppt. quinonechloroimines have been evaluated. The following results have been obtained: benzidine: $\text{C}_{12}\text{H}_8(\text{NH}_2)_2 \cdot 2\text{HCl} + 3\text{Cl}_2 = \text{C}_{12}\text{H}_8\text{N}_2\text{Cl}_2 + 6\text{HCl} + 58.40 \text{ Cal.}$; $\text{C}_{12}\text{H}_8(\text{NH}_2)_2 \cdot 2\text{HCl} + 3/2\text{Ca}(\text{OCl})_2 = \text{C}_{12}\text{H}_8\text{N}_2\text{Cl}_2 + 3/2\text{CaCl}_2 + 3\text{H}_2\text{O} + 80.21 \text{ Cal.}$; dianisidine: $\text{C}_{12}\text{H}_6(\text{OMe})_2(\text{NH}_2)_2 \cdot 2\text{HCl} + 3/2\text{Ca}(\text{OCl})_2 = \text{C}_{12}\text{H}_6(\text{OMe})_2\text{N}_2\text{Cl}_2 + 3/2\text{CaCl}_2 + 3\text{H}_2\text{O} + 89.72 \text{ Cal.}$; *p*-aminophenol $\text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2 \cdot \text{HCl} + 2\text{Cl}_2 = \text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{NCl} + 4\text{HCl} + 39.92 \text{ Cal.}$; *p*-amino-*p'*-hydroxydiphenyl: $\text{OH} \cdot \text{C}_{12}\text{H}_8 \cdot \text{NH}_2 \cdot \text{HCl} + 2\text{Cl}_2 = \text{O} \cdot \text{C}_{12}\text{H}_8 \cdot \text{NCl} + 4\text{HCl} + 30.99 \text{ Cal.}$ The formation of small quantities of decompn. products renders the thermal data obtained for picramic acid untrustworthy. It is not possible to det. the heats of formation of the corresponding Br derivs., the main reaction being always accompanied by a bromination of the nucleus. From the present data and those of Swientoslawski (*loc. cit.*) on *p*-phenylene- and *p*-naphthylenediamines a mean value of 21.92 cal. is obtained for the difference between the heats of reaction using bleaching powder and Cl water. Replacement of the benzene nucleus by diphenyl causes a mean decrease of 9.47 cal. in the heat of reaction. Comparison of the thermal data for benzidine and dianisidine shows that the introduction of electropositive methoxy groups into the nucleus results in an increased thermal effect. 3,3'-Dimethoxydiphenoquinone-4,4'-dichlorodiimine is formed as a reddish brown, amorphous, unstable ppt. on treating solns. of dianisidine dihydrochloride with bleaching-powder soln. 4,6-Dinitro-*o*-benzoquinone-2-chloroimine is formed as a yellow ppt. on treating a soln. of picramic acid in presence of HCl with Cl water in the cold. The substance, which has not yet been obtained pure, is very sol. in acetone, AcOH and alc.

B. C. A

Thermochemical researches on diazo compounds. W. SWIENTOSLAWSKI. *Roczniki Chem.* 5, 214-31(1925).—The methods employed by S. (cf. C. A. 12, 1640) for the thermochem. investigation of diazo compds. are described and illustrated by the cases of aniline and *p*-bromoaniline. From these, and from previously published results (*loc. cit.*), the following conclusions are reached. Substitution in the benzene ring of electronegative groups has not a const. effect on the heats of various reactions of substituted anilines. Thus, where q_{am} , q_{dz} , q_n , and q_{is} , are, resp., the heats of formation of amine hydrochloride, of diazonium chloride and of *n*- and *iso*-diazohydrate Na salt, i_n and i_{is} , the heats of isomerization of the diazonium into the *n*- and *iso*-diazohydrate forms, and *A* and *B* the heats of diazotization of amine and of coupling of *n*-diazohydrate with solid β -naphthol, the effect of electronegative substituents is to diminish q_{am} , q_{is} and *A*, and to enhance q_{is} , q_n and *B*, while i_n and i_{is} remain unchanged. These differences may be considerable, q_{am} varying from 7.60 to 1.81 cal., *A* from 19.97 to 12.47 cal., q_n from 3.77 to 5.65 cal. and q_{is} from 8.80 to 11.00 cal. *B* increases inversely with *A*, so that $A + B + i_n = 50 \text{ cal.}$ is const., and independent of substitution, the derivs. of *o*- and *p*-aminobenzoic and of sulfanilic acids deviating, however, from this rule. The mean values of i_n and i_{is} are +0.5 and -2.3 cal., and in all cases $q_n < q_{is}$, the difference being from 5 to 6 cal. Contrary to Hantzsch's statement, $i_{is} - i_n$ gives a negative mean value of about 3 cal., although in the isomerization of salts heat is evolved, since $q_n < q_{is}$, so that $(q_{is} + i_{is}) - (q_n + i_n) = +3 \text{ cal.}$, the salt of *p*-sulfodiazobenzene being, however, an exception to this rule.

B. C. A

Thermochemical researches on the diazo derivatives of aminophenols. W. SWIENTOSLAWSKI AND (MLLE.) Z. BLASZKOVSKA. *Roczniki Chem.* 5, 233-51(1925). cf. preceding abstr.—Certain reactions of picramic acid and of *p*-amino-*p'*-hydroxydiphenyl are examd. thermochemically. The heats of formation of the hydrochlorides are, resp., 0.746 and 6.0 cal., of formation of Na salts 10.20 and 6.41 cal., of diazotization 25.56 and 19.91 cal. The product of diazotization of picramic acid is a quinone diazide which yields with NaOH a normal diazohydrate salt, 9.34 cal. being evolved. The heat of coupling of the quinone diazide with β -naphthol is about 41 cal. With the aminohydroxydiphenyl, the heat of formation of the Na salt of the diazohydrate is 24.13 cal., and of coupling with β -naphthol about 27 cal. Picramic acid exhibits greater divergences from the properties of other amines than the aminohydroxydiphenyl.

The data of thermochemistry. F. RUSSELL BICHOWSKY. *Ind. Eng. Chem.* 18,

417-8(1926).—The unsatisfactory state of existing tabulations of thermochem. data is pointed out and a plea made for new investigations. F. R. BICHOWSKY

The electrical conductivity of crystalline, molten and dissolved $\text{AgTi}(\text{NO}_3)_2$. A. I. RABINOVICH. *J. Russ. Phys.-Chem. Soc.*, Phys. Part, **56**, 555-9(1924); *Trans. Karpov Inst. Chem.* **1925**, No. 4, 41-55.—The comparison of elec. cond. of the double salt $\text{AgTi}(\text{NO}_3)_2$ in cryst. and supercooled state has shown that the degree of breaking down of the crystal space lattice equal to 1.30 at the m. p. of the salt (82.5°) falls rapidly to 1:130,000 at 65°. The elec. cond. and viscosity of various systems from dil. soln. to pure molten salt have been studied at 100°. R. PIROOMOV

The hydrolysis of aluminum sulfate—an application of the quinhydrone electrodes. A. J. PELLING. *J. Chem. Met. Soc. S. Africa* **26**, 88-95(1925).—The degree of hydrolysis of $\text{Al}_2(\text{SO}_4)_3$ is calcd. at 15° and six concns. from the H-ion concn. as detd. by measuring, to a precision of 0.0001 v., the e. m. f. of the cell $\text{H}_2 | \text{Al}(\text{SO}_4)_3 \text{ aq} | \text{satd. KCl} | \text{Hg}_2\text{Cl}_2$. Corresponding measurements, to a precision of 0.0005 v., were made with the cell $\text{Pt} | \text{quinhydrone} + \text{Al}_2(\text{SO}_4)_3 \text{ aq} | \text{satd. KCl} | \text{Hg}_2\text{Cl}_2$, but were not used in the calcn. The first stage in the hydrolysis is represented by either (1) $\text{Al}(\text{SO}_4)_3 + 2\text{H}_2\text{O} = \text{Al}_2(\text{SO}_4)_2(\text{OH})_2 + \text{H}_2\text{SO}_4$ or (2) $\text{Al}_2(\text{SO}_4)_3 + 2\text{H}_2\text{O} = 2\text{Al}(\text{SO}_4)(\text{OH}) + \text{H}_2\text{SO}_4$, for which the respective hydrolysis consts. are $K_1 = x^3/(1-x)^2V$ and $K_2 = x^2/(1-x)V$, where x is the degree of hydrolysis and V is the diln. K_2 is a better const. than K_1 in contrast with the result at 25° of Denham (cf. *C. A.* **2**, 1089). The results are tabulated. P. believes the Clark shaking H electrode is better for this work than the ordinary bubbling electrode used by Denham. The differences between the H-ion values as detd. by the two electrodes are supposed to be due partly to exptl. error and partly to "salt effect". E. R. SMITH

The direct oxidation of the manganous ion to permanganate. A. N. CAMPBELL. *Trans. Faraday Soc.*, Feb. 22, 1926 (advance proof). Manganous ion can be anodically oxidized to permanganate. The optimum conditions are: c. d., 17 amp. per square decimeter; anolyte, a satd. soln. of K_2SO_4 in H_2SO_4 containing 198 g. per l.; time, 3 hrs.; Mn content, 0.7767 g. per l. of electrolyte; temp. about 0°. The catholyte consists of the Mn in a satd. soln. of K_2SO_4 and is placed in a porous pot. The anode is a smooth Pt foil; the cathode a Pt crucible. Neither NO_3^- nor Cl^- may be present. Spectrographic studies show MnO_4^{2-} to be the only oxidation product formed. A. G.

Presence of divi-manganese (atomic number 75) in manganese salts. V. DOLEJŠEK AND J. HEVROVSKÝ. *Chem. Listy* **20**, 4-12(1926).—In electrolysis of MnSO_4 solns. with a dropping Hg cathode, registered by means of Hevrovsky's polarograph, an impurity present in proportion of $1/10,000$, and sepg. at a potential of 1.00 v. with respect to the normal calomel electrode is detected. To collect a large quantity of this impurity a Pt foil, placed in elec. contact with Mn amalgam was immersed in a concd. soln. of MnSO_4 , to collect a deposit of any metal more noble than Mn present in the soln. The deposit was dissolved in HCl, and pptd. by H_2S . The filtrate yields a residue, which, when examd. X-spectroscopically, shows lines of element at no. 75 ($L_{\alpha_1} = 1430 \times 10^8 \text{ U}$, $L_{\beta_1} = 1253.3 \times 10^8 \text{ U}$, $L_{\beta_2} = 1204.3 \times 10^8 \text{ U}$ and $L_{\gamma_1} = 1059 \times 10^8 \text{ U}$). The authors criticize the work of Noddack and coworkers as inconclusive. Their X lines, when subjected to analysis, appear to be due to Tl and Zn. Because of this, it is doubtful whether they really discovered this element, so that their name rhenium can be superseded by the old Mendelyev name divi-manganese. F. C. KRACEK

Conductivity measurements in mixtures of methanol and ethanol. HEINRICH GOLDSCHMIDT AND HARALD ARFLOT. *Z. physik. Chem.* **119**, 1-7(1926).—Cond. of HCl and NaBr at various dilns. in mixts. of MeOH and EtOH. The cond. of the acid and the salt vary in like manner with change in composition of the solvent, in contrast with the marked difference in their behavior on addn. of H_2O to alc. solns. Cf. *C. A.* **18**, 1603. B. H. CARROLL

Electric conductivity in monocrystals and crystalline aggregates. A. JOFFÉ AND E. ZECINOWITZER. *Physica* **6**, 36-9(1926) (in German).—The cond. of NaCl monocrystals, obtained artificially from molten salt, was measured. The same crystals were then subjected to compression at high temps. (600°) and thus plastically deformed (d. changing from 2.9 to 2.0 mm) into a cryst. aggregate. It was found that as long as no free crystal faces appear, no change in cond. occurs; it was 1.13 and 1.09×10^{-7} before and after compression at 530°; 3.90 and 3.93×10^{-7} at 597°. It is plausible to explain the cond. solely by normal dissoen. of the lattice, not by local "Auflockerung". Also in *Z. Physik* **35**, 446-8(1925). B. J. C. VAN DER HOEVEN

Refractive index of organic substances and atomic structure. K. FAJANS AND C. A. KNORR. *Ber.* **59**, 249-65(1926). The concept of at. refraction is insufficient to account for the observed indices. F. and K. using the Lewis-Langmuir octet theory

Metastationary atomic and molecular states. ADOLF SMEKAL. *Z. Physik* **34**, 81-93(1926).—It is suggested that atoms and mols. may exist in stationary states of very short life period which are not fixed or are only partially fixed by the quantum conditions and that these states differ from those which are quantized only in their *a priori* probability. The existence of dispersion is given a phys. interpretation in this way.

H. C. UREY

Theory of rotatory polarization. R. DE MALLEMANN. *Ann. phys.* [10] **4**, 456-8 (1925); cf. *C. A.* **19**, 3059.—Theoretical. Mistakes in earlier papers are pointed out and corrected. The rotatory power is independent of the choice of axes used to describe the symmetry of the mol., but in anisotropic liquids or gases a structural rotatory power exists which is absent in ordinary liquids or gases.

The chemical action of α -particles on acetylene. W. MUND AND W. KOCH. *J. Phys. Chem.* **30**, 289-93(1926); cf. *C. A.* **20**, 540.—The ratio of the no. of reacting mols. to the no. of ions produced for polymerization of C_2H_2 is not influenced by the amt. of air, change of pressure or change of temp. The mean value of 11 measurements is 20.2.

L. D. R.

Atom disintegration by α -rays. III. The disintegration of carbon. HANS PETTERSSON. *Anz. Akad. Wiss. Wien* **61**, 130-1(1924).—Under the influence of α -rays C yields H and α -particles. The latter have a range of 10.5 cm. The H-particles have been observed in the direction of, as well as perpendicular to the direction of the α -rays and found to have ranges of 8 and 16 cm., resp. Atom fragments of range 1.5 cm. have been observed. The results with C as well as those with Be and Si are in agreement with P.'s explosion theory of atom decompn. **IV. Decomposition of nitrogen and oxygen—helium as a product of disintegration.** GERHARD KIRSCH. *Ibid* 131.—When N and O are subjected to rapid α -rays H, He and secondary α -rays result. The dependence of the no. and the range of the secondary rays upon exptl. conditions makes it improbable that they come from the primary radioactive substance. The energy of the bombarding α -particles is transferred to that of the H.

E. R. SCHIERZ

The chemical action of radium emanation. XVI. The action on potassium dichromate, potassium chromate and potassium permanganate. ANTON KAILAN. *Anz. Akad. Wiss. Wien* **61**, 161-2(1924).—Aq. solns. of $K_2Cr_2O_7$ (I), K_2CrO_4 (II) and $KMnO_4$ (III) contained in glass vessels with walls 1 mm. thick have been subjected to the action of Rn from a prepn. contg. 110 mg Ra for a period of 2 mos. I was reduced at the rate of 3×10^{14} mol./sec.; III in neutral and N/80 acid soln. at the rate of 1.5×10^{12} mol. sec., and in N/18 alk. soln. approx. 5×10^{12} mol./sec. The rate of II, though appreciable, is less than that of I.

E. R. SCHIERZ

The alteration of benzene vapor under the influence of α -particles. W. MUND

AND E. BOGAERT. *Bull. soc. chim. Belg* **34**, 410-5(1925).—In 2 expts in an approx. 175-cc. vessel, contg. C_6H_6 vapor at 100° and 0.041 curies of radon, the pressure decreased 1.04 cm. Hg in 25.7 hrs and 0.75 cm in 17 hrs. From these the no. of C_6H_6 mols. disappearing per α -particle emitted is calcd. resp. as 2.19×10^6 and 2.01×10^6 , which is the same numerically as the value (2.10×10^6) calcd. by Bragg for the no. of ion pairs formed in C_6H_6 vapor by an α -particle. W. B. PLUMMER

The half period of ionium. O. KOBLIC. *Chem. Listy* **19**, 380-91(1925).—Io sep'd from 20.00 g. Joachimstal pitchblende ($63.65 \pm 0.5\%$ U) yields the same satn. current as 0.300 mg. (Io, Th) O_2 obtained from the same source. The Honigschmidt and Horowitz (*C. A.* **11**, 1581, 1598) value of the at. wt. of Io from Joachimstal pitchblende is 231.51, which places the Io/Th ratio = 3.7. Soddy and Hitchins (*C. A.* **18**, 2463) obtained 10/9 for the same ratio by an indirect method based on 1.1×10^4 yrs. for the half period of Io. K. uses the Honigschmidt value, and accordingly, 0.079 mg. Io has the same activity as Io obtained from, and in equil. with, 12,730 mg. U $_1$. The radioactive const. of Io, calcd. on the assumption of $\lambda_{Io} = 1.54 \times 10^{-10}$ is equal to $\lambda_{Io} = 2.40 \times 10^{-6}$ which corresponds to the av. life of 4.17×10^4 yrs., or a half period of 2.90×10^4 yrs. F. C. KRACEK

Scintillations in zinc sulfide. J. STALONY-DARBOVSKI. *Roczniki Chem.* **5**, 193-214 (1925).—The luminescence produced by thorium in thin layers of ZnS is investigated. It is found that each scintillation, on examn. through a lens magnifying up to 40 times, consists of a small bright spot of light surrounded by a diffuse aureole, the shape of which depends on the location of the Th atom in the layer, and the diam. of which varies from 0.1 to 0.3 mm. The duration of the scintillations is det'd. in 3 ways, the first method being that of Wood (*Phil. Mag.* **10**, 427-30(1905)), depending on the measurement of the length of the arcs of light appearing on the screen during its rapid rotation. In this way, the duration of the scintillations is shown to be of the order of $1/200$ sec. and not, as Wood found, $1/20,000$ sec., the greater part of the arc being invisible at the high speeds of revolution used by him. In the second method, the no. N of scintillations appearing per min. on a fixed screen of 1 sq. mm. surface are det'd. Before this screen is placed a revolving opaque glass disk, possessing a window in the form of an arc of angle α , and the no. of scintillations per min., $N_{\alpha\beta}$, is again counted, being less than N but greater than $N\alpha/2\pi$, the no. which would appear if the scintillations were of infinitely short duration. The duration of the scintillations, t , is given by the formula $t = (N_{\alpha\beta} - N\alpha/2\pi)/Nn$, where n is the no. of revolutions per second of the disk. The minimal value of t found was $1/29$ sec. The third method is more convenient than the preceding ones, and gives more accurate results. A streak of radioactive matter is disposed radially on a glass disk, and is covered on the other side by a large sector of black paper. This disk is placed before a screen of ZnS, of area 0.5 sq. cm., and revolved, the speed being reduced until the sparks cease to be visible, when $t = \beta/2\pi n$, where β is the angle between the streak of radioactive matter and the edge of the sector. In this way, t was found to be $1/6$ sec., results of the same order being obtained with various samples of ZnS. A disk phosphoroscope is also described, in which half the revolving disk is within a box contg. the source of illumination, the other half showing bands of phosphorescence strikingly similar to those obtained with thorium as the excitant, i. e., a bright band followed by a larger diffuse region; this suggests that the mechanism of luminescence is the same in both cases. B. C. A.

Diamagnetism and the anomalous Zeeman effect. P. TARTAKOVSKII. *Z. Physik* **34**, 216-26(1925).—In the anomalous Zeeman effect it is necessary to multiply the precessional frequency of the electrons by the Landé g factor in order to secure the proper additional energy of the electrons in the magnetic fields. Therefore, this factor must also be used in calcg. the diamagnetic susceptibility. T. does this and calcs. the susceptibility of He, Li, Na, K, Cs assuming that the orbits are elliptical but that the effective quantum no. and effective at. nos. are to be used. The exptl. data on the ionic susceptibilities are used in calcg. the values for the neutral atoms. H. C. UREY

The influence of degassing a metal plate bombarded with cathode rays on the liberated electron rays. CARL TINGWALDT. *Z. Physik* **34**, 280-4(1925).—It is found that degassing the reflector and applying a compensating potential for the elec. double layer on the plate causes the reflection of electrons to be independent of the angle of incidence for electrons of 4 to 500 v. velocity. H. C. UREY

The ionization of hydrogen by slow electrons. HARTMUT KALLMANN AND MAX BREDIG. *Z. Physik* **34**, 736-50(1925), cf. *C. A.* **20**, 332. The ions produced in H by 15-30 v. electrons were identified by magnetic deflection. H^+ , H_2^+ , and H_3^+ appear at very nearly the same potential. H^+ is observed at higher potentials than the others and is due to dissociation of H_2^+ after falling through the elec. field and before entering

the magnetic field. H_2^+ is the most abundant and is the primary product. The disappearance curves of the ions with decreasing exciting potential and the effect of pressure on the relative intensities indicate that H^+ and H_3 are produced by secondary reactions. The H_3^+ may result from a tertiary reaction but the evidence is not conclusive. H. C. UREY

The action of an external metal mantle on a glow discharge. SR. PROCOPIU. *Physik. Z.* 27, 57-8(1926).—A glow discharge (420-550 v., 10^{-5} to 10^{-3} amps.) can be interrupted by connecting a metal ring, which surrounds the tube on the outside with the cathode. The ring has to be near the dark space or the first two or three layers of the positive column; nearer the anode the current only decreases, near the cathodic glow it increases somewhat. With potentials above 550 v. the effects are less marked. The tube was 45 cm. long and had 0.3 mm. Hg pressure. (Cf. Dunoyer and Toulon, C. A. 19, 602.) B. J. C. VAN DER HOEVEN

Why are the stability conditions for an electric arc the reverse of those for a triode? H. BARKHAUSEN. *Physik. Z.* 27, 43-6(1926).—In an elec. arc a current change causes a potential change (de/di negative, labile for $-de/di > R_a$, the external resistance); in a triode the potential change is primary and causes the current fluctuation (de/di also negative, labile for $-de/di < R_a$). Mathematically the relations can be derived if a positive inductance is assigned to the arc, a positive capacity to the triode. B. J. C. VAN DER HOEVEN

Production of ultra-violet light by the impact of low-speed electrons on a metal surface. PIERRE BRICOUT. *Compt. rend.* 182, 213-5(1926).—A cylindrical quartz high-vacuum tube is described, contg. a straight filament (Pt covered with alk. earths) in the axis, a flat Pt anode near to the filament and in one plane with it (no direct radiation can hit the anode) and a cylindrical Mo plate surrounding both elements. The anode is brought to a potential of some volts, the Mo plate on a potential of several thousand volts, a magnetic field parallel to the filament causes the electrons to deflect and bombard the anode. The radiation produced is, after concn. by a fluorite lens, analyzed in a spectrograph. For an electron current of 1 ma., anode of 10 sq. mm. at a potential of 6 v. radiation of between 2300 and 2100 Å. U. was emitted by the metal. B. J. C. VAN DER HOEVEN

Model gratings to illustrate the diffraction of X-rays by crystals. W. L. BRAGG. *Mem. Proc. Manchester Lit. & Phil. Soc.* 69, 35-8(1925).—A half-tone printing process plate, ruled with 400 lines to the in., is laid with its ruled side in contact with a fine-grained photographic plate and exposed to light. Several exposures are taken on the same plate, the original grating being moved a fraction of $1/400$ in. between each exposure. By varying the time of exposure and length of movement of the original grating, any type of group of lines may be obtained on the photographic plate. When these plates are developed and used as gratings with a monochromatic source of light, the intensities of the different orders depend upon the arrangement of the lines, just as the intensities of diffracted X-rays depend upon the arrangement of at. planes. Spectra of the rock-salt (111) and diamond (111) types were reproduced. R. J. HAVIGHURST

Some studies of the Stark effect. C. E. DEPPERMAN. *Astrophys. J.* 63, 33-47 (1926).—The Stark effect for the Zn triplet $1s - 1p$ was studied under fields from 30,000 to 40,000 v. per cm., and with dispersions ranging from 10 to 4 Å per mm. The Stark effect, if any, was found to be negligible. Nagaoka's positive results are apparently due to the pole effect. Preliminary results for the similar $1s - 1p$ triplet of Cd and the Tl line $1\pi - 1\sigma$ (5350.5 Å. U.) also show no appreciable Stark effect. W. F. MEGGERS

Electro-optical investigations in sodium-vapor. (Anomalous electrical double refraction; Stark effect of the resonance radiation.) H. KOPFERMANN AND R. LADENBURG. *Ann. Physik* 78, 659-79(1925).—A positive elec. double refraction of Na vapor in the immediate vicinity of the D_2 line is exptly. established, but at the D_1 line it is not seen and is certainly less than $1/10$ as large as at D_2 . This effect has nothing to do with the usual cause of elec. double refraction, viz., the orientation of asymmetrical atoms in the field; it rests rather on the elec. displacement of the D_2 line (the quadratic Stark effect), since for D_2 the π - and σ -components are displaced toward red by different amts., but for D_1 both components are equally displaced. W. F. M.

A relation between the chemical elements in the effect of an electric field upon their series lines. J. STARK. *Ann. Physik* 78, 425-33(1925).—The Balmer series of H is represented by $\nu = 2w - mw$ and it is pointed out that so far as our knowledge goes all other elements are characterized by several series, i. e., instead of a single series of terms mw as in H there are at least 5 series of terms, ms , mp , md , mf_1 and mf_2 . It is recognized that the type and magnitude of the Stark effect of a series line of an element

is detd. by its term, and the effects for the different elements may be compared in relation to their terms. For purposes of this comparison the difference of the term for a series line of an element as compared with the term of the H-series line of the same no. is called the *H-difference* of the series line first mentioned. In 3 tables the available observational data are compiled for *ms*, *mp* and *md* series lines; the element, wave length, series notation, H-difference and $\Delta\lambda$ effect in a field strength of 28,000 v. \times cm.⁻¹ being given for each line. The following law or regularity is formulated: For lines of the *ms*-, *mp*- and *md*-series of heavy elements the $\Delta\lambda$ -effect of an elec. field has the same algebraic sign as the H-difference of the terms, and for a given type of series in different elements the magnitude is smaller the larger the corresponding H-difference is. It is seen also that for every element the H-difference in any type of series decreases with increasing member no. *m* and in fulfilment of the above law the corresponding $\Delta\lambda$ -effect increases with higher members of series. Reduced to the same H-difference the $\Delta\gamma$ -effects are largest for *ms*-series and decrease in the order *ms*, *mp*, *md*. Some general considerations of electron displacement and imposed elec. field are outlined.

W. F. MEGGERS

The quenching of resonance radiation and the breadths of absorption-lines. R. W. DITCHBURN. *Proc. Cambridge Phil. Soc.* 23, 78 84(1926). C. C. KIESS

Polarization of radiation scattered by an electronic system in a magnetic field. G. BREIT. *J. Optical Soc. Am.* 12, 195-205(1926); cf. *C. A.* 20, 542.—The classical theory of the polarization of radiation scattered by an electronic system leads to results which cannot well be harmonized with exptl. facts. A quantum hypothesis is made which appears to account for the phenomena more satisfactorily. C. C. KIESS

Arc spectrum of phosphorus. N. K. SUR. *Nature* 116, 542(1925).—Series relations arising from Saltmarsh's observations (*C. A.* 18, 2286) are pointed out.

B. C. A.

Ultra-violet absorption spectra of mono- and di-derivatives of benzene. F. W. KLINGSTEDT. *Acta Acad. Aboensis Math. Phys.* 3, 1-82(1924); cf. *C. A.* 17, 686.—The absorption of ultra-violet radiations up to 1944 Å. U., has been examd. quantitatively for toluene, phenol, aniline, the xylenes, cresols, toluidines and dihydroxybenzenes. All compds. which show narrow absorption bands in the vapor state give also in indifferent solvents spectra with narrow (10-30 Å U.) bands similar to the spectra of their vapors. The characteristics of the absorption spectra of the compds. mentioned are described. Substitution in the benzene nucleus by Me, hydroxyl, or amino groups results in a displacement of the selective absorption towards the red, an increased total absorption in the inner ultra-violet, an increase in the mol. absorption coeff. of the strongest inner bands, and a change in the no., form and distribution of the different bands. Similar effects are observed in substituted toluene derivs. The selective absorption of *p*-derivs. is distinguished, apart from the nature of the substituent, by a large no. of sharply defined narrow bands, begins at longer wave lengths, and is more marked in the extreme ultra-violet than is the case with the other isomerides. *o*- and *m*-Derivs. are similar in the middle ultra-violet and to a certain extent in the outer ultra-violet. The absorption spectra of the hydrocarbons examd. have no definite benzene character. The absorption spectra of the phenols, apart from those parts of the spectra of *p*-derivs. which contain numerous bands, are generally similar. The amines are generally similar in their absorption spectra up to the outer ultra-violet, except that aniline and *p*-toluidine have narrow bands in the inner ultra-violet.

B. C. A. •

The effect of pressure on the absorption of hydrogen chloride in the infra-red. GORTHOLO BECKER. *Z. Physik* 34, 255-72(1925).—The effect of pressure on the absorption of the 3.4 μ vibration-rotation band of HCl was studied. The absorption was increased by increased pressure due to air and also due to increasing the pressure of HCl, keeping the product of density and thickness of layer const. It is found that this is due to the broadening of the lines but that the broadening does not depend on the no. of collisions alone.

H. C. UREY

Measurements of the rotation spectrum of HCl in the long-wave-length infra-red. M. CZERNY. *Z. Physik* 34, 227-44(1925).—Measurements have been made for the first time on a pure rotation spectrum of a diatomic mol. The lines were sepd. by a diffraction grating. A water-free chamber was used for the expts. and the necessary windows consisted of Japanese lacquer which was shown to transmit 99% of the light. Seven absorption maxima were observed in the region from 42 to 100 μ which had nearly const. frequency differences. It is necessary to use half quantum nos. in order to calc. the frequencies from the usual theory of band spectra. The data agree with the data on the vibration-rotation spectrum except for a small const. differenc. H. C. U.

A second spark spectrum of neon. LÉON BLOCH, EUGÈNE BLOCH AND GEORGES

DÉJARDIN. *Compt. rend.* **182**, 451-2(1926).—The method of oscillating discharge in electrodeless tubes has permitted recognition of 3 successive ionizations for A, Kr, Xe (cf. *C. A.* **19**, 1988). Similar expts. have produced a new spectrum of Ne which it appears reasonable to consider as the second spark spectrum, Ne III. A table of about 100 lines (2263.17 to 3786.29 A. U.) is given to describe this spectrum. W. F. M.

Spark spectrum of lithium. S. WERNER. *Nature* **116**, 574(1925).—With an app. including a very intense source of light, and so arranged that fluorite windows are not introduced in the path of light, the classification of the spectrum denoted by Schüller as the doublet system of the Li II spectrum has been extended, and the conclusions already reached (*C. A.* **19**, 1375) have been confirmed. B. C. A.

The interpretation of the alkaline earth spectra by models. GREGOR WENTZEL. *Z. Physik* **34**, 730-35(1925).—A discussion of the structure of the alk. earth spectra on the basis of theories of others and the assignment of the spark X-ray levels to the general scheme of multiplet levels. H. C. URKY

The vacuum spark spectra of some of the heavier elements, and series classification in the spectra of ionized atoms homologous with copper, silver and gold. J. A. CARROLL. *Trans. Roy. Soc. London* **225A**, 357-420(1925).—With the vacuum grating spectrograph the spark spectra of the following elements were photographed in the extreme ultra-violet: Hg, Ga, In, Tl, Ge, Sn and Pb. The wave lengths derived from measurement of the plates are tabulated. The lines of Tl have been detd. within a few hundredths A. U. and are, therefore, recommended as standards of reference for wave-length measurements in the extreme ultra-violet down to 1000 A. U. From these data lines have been selected as representative of the doublet series systems of Hg II, Ga III, In III, Tl III, Ge IV, Sn IV and Pb IV. In each spectrum pairs of lines representing the combination $1s - 2p_{1,2}$ have been found. Additional pairs give combinations between other p , d , f and g terms. The justification for the given classifications is based on the agreement of the observed $\Delta\nu$'s and term values with the theoretical results of Sommerfeld, Landé and Hartree. An approx. relation for a sequence of d -terms is homologous spectra is $\Delta\nu(d)/C^2 = \text{const}$, where C is the charge on the core of the atom. C. C. KIESS

Arc spectrum regularities for ruthenium. W. F. MEGGERS AND OTTO LAPORTE. *J. Wash. Acad. Sci.* **16**, 143-54(1926).—In a preliminary note (cf. *C. A.* **19**, 2601) the identification of the term with lowest energy in the arc spectrum of Ru as a result of under-water spark absorption observations was announced. Zeeman effect measurements show that this is a quintet-F term. Eighteen multiplets contg. about 160 lines are given as representative of quintet, triplet and inter-system term combinations. A table of relative term values is given and the electron configurations which are responsible for these terms are discussed. W. F. MEGGERS

Excitation of the second spectrum of neon by electronic impact. GEORGES DÉJARDIN. *Compt. rend.* **182**, 452-4(1926).—Spectroscopic examn. of luminous discharge in electrodeless tubes revealed a second spectrum of Ne (*C. A.* **19**, 1988), and the conditions for the excitation of this spectrum are now investigated by the method of electron impact. Using a 3-electrode tube contg. Ne at 0.01 to 0.1 mm. Hg pressure, lines appeared at 52 v. and this spectrum was completely developed at 60 v. applied potential. With gas at a pressure of 1.6 mm. Hg, lines appear between 28 and 30 v. and evidence is obtained of 2 crit. potentials, viz., 28 v. and 49 v. for the second spectrum of Ne, the difference, 21 v., being the ionization potential of the gas. The ratio of the higher crit. potential to that of ionization is 2.28 while for A this ratio has been found to be 2.24 and for Kr and Xe 2.22. The theoretical interpretation of these phenomena is still uncertain. W. F. MEGGERS

The spark between carbon rods impregnated with a mixture of oxides of molybdenum, titanium and vanadium as the source of a closely spaced line spectrum in the visible region. MARION EPPLEY. *J. Frank. Inst.* **201**, 333-5(1926).—Directions are given for coating the extremities of C electrodes with V_2O_5 , MoO_3 and TiO_2 for the purpose of securing a spectrum with closely spaced lines of nearly uniform intensity between 6678 A. U. and 3990 A. U. C. C. KIESS

The spectrum of ionized oxygen (O II). A. FOWLER. *Proc. Roy. Soc. (London)* **110A**, 476-501(1926).—New measurements of the spectrum of ionized O have been made between 6721 A. U. in the red and 1956 A. U. in the ultra-violet. About 160 of these lines have been classified as members of the doublet and quartet systems. The lowest level thus far found in each system is a p term above which come other s , p' , d , d' and f terms. If the lowest level is 1^2s the sequence of 2^2p terms suggests for it a value of approx. 240,000 cm^{-1} , which would give an ionization potential of about 30 v., in good agreement with that deduced from astrophysical data. Comparison of the O II spectrum with

N I shows close similarity between the two, the wave-nos. of several groups of O II lines being closely double those of the corresponding groups of N I. C. C. KIRKS.

A band spectrum of tin monochloride exhibiting isotope effects. W. JEVONS. *Proc. Roy. Soc. (London)* 110A, 365-90(1926).—Measurements are given on the heads of two new groups of ultra-violet emission bands due to a chloride of Sn. One group consists of two very similar systems, to which vibrational quantum nos. are assigned; the two systems have a common initial electronic state, but two distinct but evidently closely related final electronic states. The bands of both systems are degraded toward the violet. If these two systems are attributed to SnCl^{35} , certain additional nearby weaker bands fall in exactly the theoretical positions for SnCl^{37} . That the bands are due to a diatomic mol., which must be SnCl , is shown also by the structure of the systems. There is some evidence of the Sn isotope effect. In the second group of bands, which are degraded toward the red, little is known as yet about assignment into systems, or as to the nature of the emitting mol. R. S. MULLIKEN.

The magnesium hydride band spectrum. W. M. WATSON AND PHILIP RUDNICK. *Astrophys. J.* 63, 20-32(1926).—New wave length detns. of the lines in the $\lambda\lambda$ 5622, 5211 and 4845 bands have been made, and the several P , Q and R branches, all terms of which are doublets, assigned. A correlation between abnormal septis and unequal intensities in the doublets near the origins of the bands is noted. The various combination relations are tested, and is shown that the combination involving the Q branch does not hold in any one band. Rotational and vibrational quantum assignments are made, and the form of the approx. final term is found to be given empirically by $\Delta f(m) = 12.0 m - 0.06 m^2$. The predicted isotope effect for a diatomic MgH mol. exists in all the bands, namely, the occurrence of two faint companions to each band line, and with the displacements as given by the theory. Reasons for considering the carrier to be MgH are presented. A possible identification of the electronic frequency with an electron transition in the Mg atom is made. The moment of inertia of a dipolar carrier is computed to be $4.6 \times 10^{-40} \text{ gm cm}^2$, and the internuclear distance $1.7 \times 10^{-8} \text{ cm}$. W. F. MEGGERS.

The band spectrum of aluminum. G. ERIKSSON AND E. HULTHÉN. *Z. Physik* 34, 775-87(1925).—The band spectra of an Al are burning in air and H_2 are studied. The wave lengths of the heads of the Al oxide bands and of the individual lines of the Al hydride bands were measured. The oxide bands form a band group in which transitions between 8 initial vibration states and 10 final vibration states are observed. The bands for which the change in vibration quantum no. is zero fall off in intensity more rapidly than other bands. Three Al hydride bands are described which arise from transitions between two initial and two final vibration steady states. The lower states are double. H. C. UREY.

Systematic relations between electronic structure and band-spectrum structure in diatomic molecules. I. R. S. MULLIKEN. *Proc. Nat. Acad. Sci.* 12, 144-51(1926).—Recent developments in the theory of electronic band spectra are reviewed and the following simple postulates are constructed from a consideration of the structure of known band spectra, taking into account the occurrence of apparent nearly integral and half-integral rotational quantum nos., the "missing lines" near the band origins, the occurrence of P , Q and R branches, and the nature of the electronic multiplicity. (1) The electronic state of every mol. can be characterized by a term designation, e. g., 1S or 2P ; this is associated with an electronic quantum no. j_e identical with Sommerfeld's at. inner quantum no. j for the given term type. (Or in some cases (e. g., CH) each atom may have its own individual j_e , uncombined with that of the other atom.) (2) The vector or vectors j_e set themselves parallel (ϵ components) or perpendicular (σ components), or nearly so, to the nuclear angular momentum vector m , and the rotational energy term is given by the formula $E^m = Bm^2 + \frac{1}{2} = B(\sqrt{j_e^2 - \sigma^2} + \epsilon)^2 +$ (3) The mol. j has integral values for odd mols., half integral values for even mols. and is subject to the selection principle $\Delta j = 0, \pm 1$; the occurrence of P , Q and R branches being detd. in accordance with the correspondence principle. These postulates are elucidated by some supplementary remarks and conclusions. A detailed account of their application to individual band spectra, and discussion of the problems of mol. structure, and of "rotational doubling" in band spectra will be given in sep. papers. W. F. MEGGERS.

Systematic relations between electronic structure and band spectrum structure in diatomic molecules. II. The ZnH , CdH and HgH molecules and their spectra. ROBERT S. MULLIKEN. *Proc. Nat. Acad. Sci.* 12, 151-8(1926).—The band spectra of ZnH , CdH , HgH are interpreted in accordance with the general postulates given in I (cf. preceding abstract). The evidence that the emitters are those named seems

conclusive. For each mol. there are two closely related band systems having a common final limit; these are believed to parallel the transitions ${}^2P_{1,2} - {}^2S$ of the respective metal atoms, Cu, Ag and Au. Further details concerning molecular stability, the "missing lines," and the existence of double rotational terms are given. W. F. MEGGERS

Photographic spectra of tribo-luminescence. D. M. NELSON. *J. Optical Soc. Am.* 12, 207-15(1926).—Various natural and artificial substances were examined for tribo-luminescence, and of these the following three were selected for examn. with a spectrograph: sphalerite, chlorophane and artificial zinc sulfide. Disks of each, mounted on the shaft of a motor, were excited to luminescence by being rotated against brushes of various kinds. The emitted light was found to consist in each case of a narrow band of continuous radiation extending from the green into the orange with max. in the greenish yellow. C. C. KIESS

The excitation of gas spectra by chemical reactions. HANS FRÄNZ AND HARTMUT KALLMANN. *Z. Physik* 34, 924-50(1925); cf. *C. A.* 19, 2452.—In this work the excitation of the Na and Hg lines by reactions between Na and the halogens and between Hg and the halogens has been studied. Possible intermediate reactions for the reaction of Na with the halogens are presented and the energy available for the excitation of spectra for these reactions is calcd. From the calcs. it would seem that the Na lines could be excited but that the Hg lines could not. It is found exptly. that both the Na and Hg lines are excited and that the intensities are about the same for the reaction of Na and Cl_2 but that only Na lines appear for the reaction of Na and Br_2 . Only band spectra of the Hg halides appear in the Hg and halogen flames. The distribution of the intensity of these bands when excited by discharges and chem. reactions is discussed. H. C. UREY

Measurement of the coefficients of the absorption of light by fluorescent substances. S. PIENKOVSKI AND A. JABLONSKI. *J. phys. radium* [6] 6, 177-81(1925).—The fall of intensity of the fluorescence formed by a beam of parallel monochromatic rays passing through the liquid is measured photographically. From this the coeff. of absorption of light can be calcd. The method is applicable both to visible and to ultra-violet light if it is monochromatic. Results obtained for fluorescein were found to be in good agreement with those obtained by other methods. B. C. A.

Permanent modifications in fluorescent liquids. (MLLE.) M. ASTERBLUM. *Bull. inter. acad. polonaise* 7-8A, 297-318(1924).—Exposure of glycerol solns. of fluorescein to ultra-violet light results in a change in the color of the fluorescence from green to blue. The intensity of fluorescence diminishes and after prolonged exposure the soln. no longer gives out light. The soln. does not recover its initial properties on long keeping. Indication of the formation of modifications on illumination is afforded by the appearance of a new band between 4900 and 4470 Å. U. in the fluorescence spectrum and the diminution in intensity of the band at 5500 Å. U. characteristic of normal fluorescence. On prolonging the action of the exciting light the new band in turn disappears. The absorption spectrum of the modified solns. shows a decreased absorption in the region 4900 Å. U. and an increased absorption in the region below 4600 Å. U. Purely chem. processes, e. g., oxidation by the air, action of alk. impurities, etc., may bring about similar changes. The max. wave length of the light capable of producing this modified fluorescence is about 2540 Å. U. Glycerol solns. of methylene violet, corallin, crocein, esculin, erythrosin, eosin and rhodamine lose their fluorescent properties on exposure to the action of ultra-violet light. The rate at which these modifications are formed depends on the concn., in general the rate being greater the more dil. the soln. Solns. of erythrosin, eosin and rhodamine in benzyl alc. are much more sensitive to the action of light than are the corresponding glycerol solns. B. B. A.

Fluorescence and channeled absorption spectra of bismuth vapor at high temperatures. A. L. NARAYAN AND K. RANGADHAMA. RAO. *Nature* 114, 645(1924); *J. Inst. Metals* 33, 401.—At 1300° Bi vapor exhibits an absorption spectrum composed of a great no. of bands presenting a fine structure and extending from 6500 to 4500 Å. U. In this region 400 bands have been photographed, and these all shade off toward the red. The vapor emits an orange-yellow fluorescent radiation, the spectrum of which contains 24 bands between 6600 and 5050 Å. U. H. G.

Determination of the life period of the activated state of fluorescent molecules. FRANCIS PERRIN. *Compt. rend.* 182, 219-21(1926).—The value $1/4$ for max. polarization of a circular oscillator has to be changed into $1/2$; it appears from this (cf. Vavilov and Levshin, *C. A.* 17, 3838) that this form of oscillator has to be abandoned. The equation $p = p_0\eta/(\eta + s)$ ($s = (1 - 1/2p_0)RT\tau/V$), however, remains generally valid for p as a function of η (p is polarization, p_0 polarization for zero Brownian rotational motion, η viscosity, $V = N \cdot 1/\tau r^3$ the actual vol. of fluorescent substance, τ the av. life. From

this equation is found for erythrosin $t = 0.16 \times 10^{-8}$ sec., bengal rose 0.14×10^{-8} sec. in alc. soln. The p_0 and τ are generally independent of η but depend upon the dielec. const. of the solvent. If $\tau/\tau_0 = k$ a const. equal to the quantum efficiency of fluorescence, the theoretical period τ_0 can be evaluated from an equation of Einstein, it depends upon the absorptive power of the substance; its value for fluorescein in alk. aq. soln. is $\tau_0 = 0.6 \times 10^{-8}$ sec., in good agreement with $\tau = 0.4 \times 10^{-8}$ sec. for the same substance in water/glycerol mixts.

B. J. C. VAN DER HOEVEN

The decomposition of hydriodic acid in light: independence of the decomposition of hydriodic acid in light of the state of aggregation and temperature, and inquiry into the meaning of the mechanism of the process. MAX BODENSTEIN AND FRITZ LIENEWEG. *Z. physik. Chem.* 119, 123-38(1926) —The dissociation of HI in the gas phase by radiation from a Hg arc was followed by titration for I_2 and acid; the rate at 150° and 175° under otherwise identical conditions was found to be the same. In aq. soln., 1.84 mols. were found to be dissoc. per quantum of radiation of $300m\mu$ wave-length absorbed, agreeing within the limits of error with the work of Warburg in the gas phase, and fulfilling the prediction from the Einstein relation that the yield per quantum should be independent of temp. or state of aggregation. The reaction in aq. soln. was followed colorimetrically by the I formed. The reaction in the gas phase is unaffected by din with N_2 , and is not sensitized for long wave lengths by I_2 vapor, but it is still impossible on the available evidence to det. whether the primary reaction is dissoen into atomic H and I, or formation of activated HI mols. This can be done when it is found by expts. with monochromatic radiation whether I_2 vapor retards the reaction. B H C.

Evidence for the existence of activated molecules in a chemical reaction. O. R. WULF. *Proc. Nat. Acad. Sci.* 12, 129-32(1926) —On the assumption that the radiation emitted in the rapid decompn. of O_3 involves 2 mols., its wave length according to the quantum theory should be 4120 \AA . U. Actually it corresponds to an energy of twice this value, which is considered as proof of the existence of activated mols. as postulated by Arrhenius.

ARTHUR GROLLMAN

Excitation of resonance in neon by lines of the visible neon spectrum. W. DE GROOT. *Naturwissenschaften* 14, 104(1926).—If an image of the light of a Geissler tube with Ne filling is formed inside a Ne discharge tube resonance light (6402, 6334, 6143 and 6506) is observed. The same effect is found, the intensity varying with the place, owing to difference in concn. of metastable atoms, in a tube with striated discharge. If the same expt. is performed on a tube in which Ne is being excited by electron impact and the voltage so regulated that only 2s atoms are present, the red resonance light appears in a previously dark space as soon as the Geissler tube is ignited. Also in *Physica* 6, 53-6(1926).

B. J. C. VAN DER HOEVEN

The collision damping of the mercury resonance line. WILHELM ORTHMANN. *Ann. Physik* 78, 601-40(1925).—For the width of a spectral line 5 causes have been suggested: (1) Doppler effect, (2) radiation damping, (3) collision damping, (4) intermol. fields and (5) perturbations of the stationary orbits. The first 2 causes are always present, the last 3 only when the gas is investigated at high d. or mixed with other gases. In this paper it is shown that the collision damping can be studied apart from the other line-widening causes and that in the widening of the Hg resonance line 2536.7 \AA . U. by the addn. of foreign gases it plays the principal role next to Doppler effect.

COLIN G. FINK

Chrome-nickel electric ingots. J. H. HRUSKA. *Iron Age* **116**, 1801, 1845-6 (1925).—The detn. of the principal factors influencing the chem. and mech. properties of steel are most conveniently ascertained from empirical logs of various heats, chem. analyses and heat balance sheets. H. includes one of these complete records to show satisfactory practice for the manuf. of high-grade Ni-Cr steel for an approx. 5-ton ingot. Characteristics of the furnace, specifications for the metal, record of the heat, analyses, etc., are given. The heat distribution per ton of Ni-Cr steel melted in a 7-ton Heroult furnace is summarized as: steel 51.9%, slag 7.0%, cooling rings 2.8%, transformer 1.1%, radiation 37.2%, the total heat distribution being 648,100 cal. The design of molds, correct pouring temp. and segregation are discussed briefly. A. D. S.

Electrothermic manufacture of zinc. FRIDTJOF ANDERSEN. *Mödd. Sveriges Kem. Ind.* **1923**, 67-78; *J. Inst. Metals* **33**, 471-2.—A. gives an account of the electrothermic production of Zn, dealing especially with the methods used at Trollhättans Elektrotermiska Aktiebolag, Sweden. The production costs of electrothermic and electrolytic Zn are discussed. H. G.

An electric resistance furnace for high temperatures. BO KALLING. *Teknisk Tids.* **1922**, 146-7; *J. Inst. Metals* **33**, 546.—An elec. resistance furnace is described whose resistance element consists of a graphite cylinder cut up zigzag shape. With such furnaces temps. above 2000° have been attained and maintained for long periods of time. H. G.

Rating of heating elements for electric furnaces. A. D. KEENE AND G. E. LUKE. *J. Am. Inst. Elec. Eng.* **45**, 222-6 (1926).—The authors describe the method of calcg. the operating temp. and the factors of safety of furnace resistor elements for reasonable service. Problems are worked out for Ni-Cr resistors of the rod type (single banked and double banked) and of the ribbon type (single banked) to illustrate the difference in the factors of safety at a dissipation of 15 w. per sq. in. and in the cost of metal per kw. radiated at a const. factor of safety. It is pointed out that the shape of the element does not necessarily insure lower cost of metal if consideration is given to the factor of safety and the life of the element. A. D. S.

Electrolytic separation of alkali and alkaline-earth metals. R. SAXON. *Chem Trade J.* **77**, 236 (1925).—With an anode of Meldrum's acid-resisting metal and a porous cathode compartment contg. Hg, electrolysis of a paste of NaOH and water yields an amalgam contg. 3.4% of Na. The Hg is preferably covered with a little petroleum. Li, Rb, Ba and Ca have been obtained by a similar method; for the last a mixt. of the chloride, nitrate and iodide is used. B. C. A.

The electrodeposition of copper from solutions containing cuprous chloride. GUENTHER HAENSEL. *Wiss. Veröffentl. Siemens-Konzern* **4**, No. 2, 111-57 (1925).—A long series of expts. was carried out. The cuprous ion content of the solns. was detd. by means of a new rapid, analytical method employing KBrO_3 : $6\text{CuCl} + \text{KBrO}_3 + 7\text{HCl} = \text{KCl} + \text{HBr} + 3\text{H}_2\text{O} + 6\text{CuCl}_2$. The electrolyte was 3 N Cl^- , 0.25 N HCl, 0.33 A CuCl. Electrolysis proceeded smoothly when precautions were taken to exclude the air. The soly. of CuCl in various alkali and alk. earth chlorides was detd.: CuCl is most sol. in KCl and NH_4Cl solns. In all cases the cathode deposit was nodular; addn. of gelatin improved the structure. It was not possible to bring about a refining of the Cu anode such as obtains in sulfate solns. On the other hand it was comparatively simple to carry out a refining process for Bi and Sb with chloride baths. Attempt to refine Ag in a chloride bath failed. C. G. F.

The parting plant of the U. S. S. Lead Refinery, Inc. F. F. COLCORD. *Trans. Am. Electrochem. Soc.* **49** (preprint) (1926).—An electrolytic process of refining doré or impure Ag is described. The electrolyte consists of Ag and Cu nitrates, a typical compn. of which is Ag, 50 g. and Cu, 60 g./l., and in some cases a small amt. of free HNO_3 . Horizontal graphite or C plates are used as cathodes in the bottom of the cell and the doré or impure Ag is placed in a basket lined with cotton duck and mushn and immersed in the top of the soln. The Ag deposits on the cathode in cryst. form and is periodically scraped from the cathode and removed from the cell. The anodic Au residue is also removed at intervals and is purified by boiling with H_2SO_4 before being cast into bars. The cells are operated in series at 160 amp., corresponding to an anode c. d. of 40 amp./sq. ft. (4.3 amp./sq. dm.), and the cell voltage is 3 v. Details of the plant construction and operation are given. G. DUBERNELL.

The conductivity of electrolytes used in the electrolytic separation of silver and gold.

F. F. COLCORD, E. F. KERN AND J. J. MULLIGAN. *Trans. Am. Inst. Mining Met. Eng.* 1926, No. 1574-D, 9 pp.—The sp. cond. of pure and mixed solns. of AgNO_3 and $\text{Cu}(\text{NO}_3)_2$ up to 80 g./l. are given. $\text{Cu}(\text{NO}_3)_2$ increases the cond. about twice as much as AgNO_3 . It was found that HNO_3 was reduced and NH_4NO_3 formed in the refining electrolyte, which was dil. in HNO_3 and concd. in metal. This accounted for the "aging" of the electrolyte. Sp. cond. curves are given showing the increase due to NH_4NO_3 , which was comparable to that with $\text{Cu}(\text{NO}_3)_2$. Increasing AgNO_3 and $\text{Cu}(\text{NO}_3)_2$ concns. gives coarser Ag crystals at the cathode; less than 40 g./l. of AgNO_3 tended to give fine crystals. The presence of NH_4NO_3 is considered beneficial if both the Cu and the Ag concns. are above 50 g./l.; it tends to give more compact and finer Ag crystals. G. DUBPERNELL.

Refining of silver by electrolysis. A. A. BULAKH. *J. Russ. Met. Soc.* 1925, Pt. 1, 289-96.—This is a discussion of a modified improved bath for the electrolytic refining of silver. Several diagrams of the bath are given. J. S. JOFFE.

Studies on electroplating. VI. Barrel plating. A. Preparation of the work. W. E. HUGHES. *Metal Ind.* (London) 28, 101-3(1926); cf. *C. A.* 19, 3223, 20, 713.—Various methods of cleaning objects preparatory to barrel plating are considered, tumbling barrels, sand blasting, pickling, electrolytic cleaning in boiling NaOH and the bright dipping of brass and Cu. The compns. of 4 representative bright dips taken from the literature are given and discussed and their use and maintenance are reviewed. G. DUBPERNELL.

"Bugs" increase profits in plating practice. W. S. BARROWS. *Can. Foundryman* 15, 24-5(1924); *J. Inst. Metals* 33, 474.—If alk. solns. are used to remove grease or oil from polished castings before plating, the soln. should be heated to a temp. at least as high as the m. p. of the grease to be removed. If paraffin is used in the grinding, it is particularly important to use a very hot cleaning soln., but if tallow is used instead of paraffin, a cooler cleaning bath will serve. In Ni-plating, with a simple double sulfate soln., $5\frac{1}{2}^\circ \text{Bé.}$ should not be exceeded. The addn. of 2 oz. H_3BO_3 per gallon will assist in the production of fine, tough, white deposits which will "color" easily, while the addn. of 1 oz. NH_4Cl per gallon gives a deposit that is more mat and a dull white in color. H. G.

Chromium plating on printing plates. H. E. HARING. *Metal Ind.* (N. Y.) 24, 68-9(1926); cf. *C. A.* 20, 552. G. DUBPERNELL.

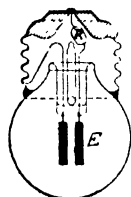

Chemical analysis and the electroplater. JOSEPH HAAS AND E. R. UNRUH. *Metal Ind.* (N. Y.) 24, 16-7, 70-2; *Metal Ind.* (London) 28, 225-6, 243, 267(1926). A general article considering the application of chem. analysis and scientific control to electroplating processes. Scientific control in electroplating includes (1) chem. analysis of plating chemicals and solns.; (2) regulation of elec. conditions; (3) records of results; (4) experimentation with solns. under varying conditions; (5) proper interpretation of 1, 2, 3 and 4 collectively. These topics are discussed and their application is considered. Sample forms are shown for recording analyses and other data on Ag and Ni solns. G. DUBPERNELL.

Control storage batteries. Their characteristics, methods of operation and charging equipment. E. A. HOXIE. *Gen. Elec. Rev.* 29, 232-42(1926). A consideration of the important points to be considered in selecting a battery best adapted to a definite case and in maintaining it so as best to realize the advantages derived from its use. General battery characteristics, types, methods of operation and detn. of battery capacity are discussed, also low-voltage control, floating and charging app. and motor generator sets. A scheme of connection when 140 v. generators are used is indicated. Advantages claimed for the use of 60-cell batteries include maintenance of the battery in a fully charged condition, a longer useful life, economy and simplicity. Each advantage is discussed. The requirements of a floating and charging source for control batteries are summarized. Selection of a motor-generator set for a 60-cell battery is aided by reference to a table that indicates the size of a 140 v. generator set for floating and charging. W. H. BOYNTON.

The Edison accumulator. CLAUDE DE ALBERTIS. *Bull. assoc. ing. éléc. Montebore* [7] 1, 160-70(1923); *J. Inst. Metals* 33, 468.—The manuf. of Edison accumulators at the Edison Works in Orange, New Jersey, is described. The most important operation is the prepn. of the positive plates, which consist of a no. of Ni-plated steel tubes packed with $\text{Ni}(\text{OH})_2$. The tubes are made of steel ribbon, which is perforated and then plated with Ni in a bath of NiSO_4 . After plating, the strips are heated to a high temp., so as just to melt the Ni. A sound coating which will not flake off is thus ensured. In order to assist the oxidation of the $\text{Ni}(\text{OH})_2$, which takes place during charging, the

NiO is packed in the tubes in layers, with pure Ni separators between them. These Ni separators are only $1/1000$ mm. thick, and are made by depositing thin layers of Ni and Cu alternately on a revolving Cu cylinder. When 125 layers of each have been deposited, they are removed from the cylinder and cut up into squares. The Cu is then dissolved, leaving a no. of thin leaves of Ni. The advantages and uses of the Edison accumulator are described, and an account of the chem. reactions during charging and discharging is given. H. G.

Recent developments of Moore gaseous conductor lamps. (Neon.) D. McFARLAN MOORE AND L. C. PORTER. *Trans. Illum. Eng. Soc.*, Feb., 1926; *Elec. World* 87, 822(1926).—For some years past the smallest-wattage 110-volt incandescent lamp

ordinarily used has been the 10-watt size. The gap between this size and zero can be filled in with gaseous conductor lamps, of which a new form is described. Some of these require only 0.01 watt. One type is shown in the figure. The glow is due to corona, the electrodes becoming luminous alternately in successive half cycles of the a. c. In this particular case the bulb is spherical, 3.2 cm. in diam., and is provided with a medium screw base. The 2 straight wire electrodes *E* are of pure Mg, 2.3 mm. diam. and 11 mm. long. They are welded to the Ni lead-in wires, the parallel gap between them being about 0.8 mm. After the bulb is thoroughly exhausted it is charged to 30 mm. with a gas prepd. from com. Ne and composed principally of Ne and He. Because the resistance decreases with increasing current, a series resistance, *R*, of 15,000 ohms is used, placed in the base. On a c., as the potential is gradually increased the first faint luminosity appears at 80 volts, with 0.00002 amp. flowing. At 90 volts, with 0.00018 amp., there is full corona. Above this the current increase is proportional to the voltage, and at 142 volts the current is 0.0033 amp. A number of other types have been developed. The behavior on d. c. is interesting. If one of these corona lamps is connected in series with a resistance of several hundred thousand ohms and in parallel with a condenser, bright flashes occur at definite intervals, the frequency of which may be varied from many thousands per sec. to one flash in about five min. This property has been used in the transmission of photographs. Since there is nothing corresponding to the time lag of the incandescent lamp, due to the heating or cooling of the filament, the response to the application or cutting off of voltage is instantaneous. Various applications are suggested. C. G. F.

Electrical resistance units with large temperature coefficients. (Nitric oxides.) H. GRUSS. *Wiss. Veröffentl. Siemens Konzern* 4, No. 2, 105–11(1925).—The problem was to increase the normal temp. coeff. of Fe or Ni (which is approx. 5% per 10°) to an enlarged coeff. of about 20% per 10° . Iron wire 0.04 mm. diam. was mounted as a filament into a bulb filled with $\text{NO}_2 + \text{N}_2\text{O}_4$ mixts. of predetd. pressure. N_2O_4 was prepared by the As + fuming HNO_3 method and dried over P_2O_5 . The gas was cooled and oxidized to N_2O_4 by means of dry O_2 . The N_2O_4 was purified by fractional distn. To avoid formation of HNO_3 , last traces of moisture were carefully eliminated. Upon analysis the N_2O_4 gas was found to contain only about 0.001% impurities. The bulbs were sealed and consequently high temp. of filament and of gas corresponded to high pressures of the nitric oxide gas. Accordingly, the temp. coeff.-temp. curves show a very sudden and sharp rise which accounts for the inapplicability of these bulbs as general temp. measuring devices. Upon diluting the nitric oxide gas with an indifferent gas the curves approach a right line but the sensitiveness of the bulbs decreases to 0.8% rise in resistance per 1° . In one expt. the bulb was filled with a large excess of N_2O_4 , part of it liquefying in the bulb. A negative temp. coeff. was obtained. With a mixture of CCl_4 and H_2 the proportion of H_2 is a function of the temp. and a very large negative temp. coeff. is possible. C. G. F.

A high power laboratory for testing oil circuit breakers and other apparatus. W. R. WOODWARD. *Elec. J.* 23, 102–6(1926).—W. discusses a lab. method of testing oil circuit breakers under controlled and observed conditions. Details are given of the testing equipment including 2 generators [rated at 20,000 k. v. a. (13,200 v.) and capable of testing a 25,000 v. circuit breaker], motors, switches for voltage control, reactances, etc. A. D. S.

Ionization studies in paper-insulated cables. C. I. DAWES AND P. L. HOOVER. *J. Am. Inst. Elec. Eng.* 45, 337–47(1926).—A statement of some preliminary results, some tentative conclusions, and a description of the method developed for making measurements of the ionization phenomena occurring in paper-insulated, high-voltage power cables. A new type of bridge was devised for very accurate measurement of dielectric losses at extremely low power factors. The investigation is being conducted at the

Harvard Eng. School under the auspices of the Impregnated Paper-Insulated Cable Research Committee.

New uses for electric gas purification. EMIL ZOFF. *Chem.-Ztg.* **50**, 81-2(1926); cf. *C. A.* **20**, 1520.—This is a review of recent applications of the Cottrell-Moller method of removing dust from smoke and gas by elec. pptn. Diagrams and photographs are shown. Wide application has been possible in the briquet industry, resulting in an increase of 7.5% in output. The method is also being used in coke ovens, illuminating gas plants, gas producers, oil shale distn., H_2SO_4 plants, smelting furnaces, cellulose industry, etc. In S burners and smelting furnaces generally, the gases can be purified from a content of 0.1 g. of solids per cu. m. to 0.003 g. per cu. m. Numerous applications are also found in the cement, gypsum, lime and chem. industries generally.

Electric dust precipitation in brown coal briquet factories. F. FISCHER. *Z. Ver. deut. Ing.* **70**, 253-60(1926).—A description and diagrammatic sketch of the elec. installation are given, the high tension e. m. f. being about 55,000 v., an Al disk rectifier being used. In *briquet* manuf. the dust is produced in the drier to which the raw coal is fed. This coal contains about 58% H_2O , and is dried to a content of 14%. The amt. of dust produced depends upon the pressure at the end of the drier, the H_2O content of the raw coal, the no. of tubes in the drier, etc., but is usually about 6-8% of the raw coal handled. In the old method of dust pptn., depending chiefly upon the mech. action of baffle plates and H_2O sprays, the dust recovered contained 45% H_2O , while in the elec. process, the dust recovered contained only 8-15% H_2O . Freedom from explosion in the dust pptn. chamber is insured by maintaining the proper humidity conditions, and curves are shown giving the relation between relative humidity, rate of feed to drier, temp. of dust, etc. A crit. point in the relative humidity of the dust is found, below which the vapors are apt to ignite, particularly if there is arcing at the electrodes. This is at about 22% relative humidity. Safety devices which operate warning signals are installed to insure further against arcing and sparking. An app. for detg. the amt. of dust recovered is described, and it is found that under proper operating conditions the loss is only about 0.25% of the coal fed to the drier, while in the older methods the loss is about 1.42%. Cost figures are given for the 2 methods for installations of 1500 tons of briquets daily, and show an operating cost for the elec. method only about $\frac{1}{3}$ as great as for the old method.

5—PHOTOGRAPHY

C. E. K. MEES

Standard light source for plate testing. S. E. SHEPPARD. *Brit. J. Phot.* 72, 518-20(1925); *Phot. Ind.* 23, 924-6(1925).—Report of a committee of 8 members of the Optical Society of America presented to the 1925 International Congress of Photography held at Paris. It is recommended that: (1) The photographic unit of intensity be defined as one visual candle power of radiation having a spectral compn. identical with that emitted by a complete radiator (black body) at a temp. of 5000°K . (2) In the detn. of speed, the illumination incident on the photographic material shall be not less than 1.0, nor greater than 10.0, meter candles. (3) The exposure be non-intermittent and that the variation in exposure be produced by a variation of the time factor of exposure. G. E. M.

Determination of silver in photographic preparations. W. MEIDINGER. *Z. weiss Phot.* 23, 282-5(1925).—Practically identical results are obtainable, in the estn. of Ag in a photographic emulsion, by the 3 similar titration methods of Liebig, Eggert and Marasco. Eggert's procedure has, however, an advantage in rapidity over the 2 others. Misapprehensions in Marasco's article (*C. A.* 18, 3018) as to the soly. of AgCN in NH_3 , and the identity of Eggert's method with the earlier ones of Rebière and Dénigès, are pointed out. C. E. K. M.

Neutral salts and dyes as desensitizers of silver bromide and of bleach-out dyes. G. KÖGEL and A. STEIGMANN. *Phot. Ind.* 23, 1387-9(1925).—The investigations of Sheppard with thiocarbamide lead K. and S. to allude to a certain identity between bleach-out and AgBr sensitizers, and they show that this identity is easily comprehended on the basis of their photochem. dehydration-hydration theory. They describe a preliminary investigation of the Casolari reaction, according to which an aq. soln. of $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO}$ and NaCNS turns blue in the light of a Hg quartz lamp. $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO}$ is also a strong photographic desensitizer. The same reaction was observed with $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO}$ and either semicarbazide or thiosemicarbazide (Kögel's bleach-out sensitizers and, in the case of the latter, Sheppard's AgBr sensitizer). The Casolari reaction is very markedly inhibited by NH_3 , which also represses the desensitizing power of $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO}$. K. and S. suggest that the action of the desensitizers formed during the natural ripening of an emulsion is prevented by NH_3 . They mention similarities in the action of nitro compds. in desensitizing photographic plates and the bleaching of dyes. A. P. H. TRIVELLI

History of the toning and intensification of silver images by means of ferricyanides. J. M. EDER. *Phot. Ind.* 23, 1355-6(1925).—Priority is accorded to Selle (1865) for the use of $\text{K}_3\text{Fe}(\text{CN})_6$ with $\text{UO}_2(\text{NO}_3)_2$ for the intensifying and toning of a (collodion) Ag image. The chemistry of the reaction between Ag, $\text{K}_3\text{Fe}(\text{CN})_6$ and $\text{Ph}(\text{NO}_2)_3$ (or similar salt) was first elucidated by E. in 1876. E. remarks the importance of the reaction

between Ag and $K_3Fe(CN)_6$ in the theory of the bromoil, kodachrome and certain dye-mordanting processes.

Desensitization with basic scarlet N. R. MAUGE. *Bull. soc. franç. phot.* **12**, 127-9(1925).—A description is given of the properties and method of use of basic scarlet N.

A. P. H. TRIVELLI

H. ELFERINK

Color photography. J. G. ZIMMERMAN. U. S. 1,579,161, April 6. A sensitized plate is exposed beneath a suitable multicolor selective screen, and a colored positive is printed directly from the negative.

Photographic printing papers. J. HALDEN & CO., LTD AND J. H. W. RUMSEY. *Brit.* **237,777**, Nov. 11, 1924. In sensitizing paper or fabric for use in a ferrogallie process, the material is first coated with $BaSO_4$, together with an adhesive such as glue or gelatin, dried and then treated with a coating compn. contg. gelatin, tartaric acid, $Fe_2(SO_4)_3$ and $FeCl_3$. Gallic acid may be applied before or after printing.

Photographic and carbon tissue resist etching process for producing intaglio printing plates or cylinders. W. E. CROWE. U. S. 1,577,181, March 16.

Gelatin. A. JENNY and J. ANGERSTEIN. U. S. 1,577,642, March 23. An acid gelatin soln. is subjected to the action of an elec. current between diaphragms which sep. the soln. from the electrodes, and the soln. is afterward neutralized. This treatment serves to produce a product suitable for *photographic emulsions*.

Photographically sensitive composition. C. E. TEBBS and J. HELFRICH. U. S. 1,579,898, April 6. A film formed of a mixt. of dragon's blood, shellac and an alkali metal chromate, proof against electrolytic action, is used on printing plates in photo-engraving.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

The complex compounds of thorium and formic acid. Supplement: **Aluminum and manganese formate.** R. WEINLAND AND ADOLF STARK. *Ber.* **59B**, 471-9(1926). Th and $HCOOH$ form complex anions, the coordination no. of Th being 6 with NH_4 , Ba and Sr as cations while with K and pyridine it appears to be 5. By a binuclear formulation this hypothetical number can be avoided and Th is given the coordination no. 6. The methods of prepn. of the following compds. are given: NH_4 , Ba and Sr hexaformatothoriate, $[Th(form)_6]M_2$, (M being a univalent metal) the 2 latter with 2 mols. water of crystn. K and pyridine pentaformatothoriate, $[Th(form)_5]H$ M. hexaformatopentahydroxotrithorium perchlorate, nitrate, chlorate, thiocyanate and formate, $[Th_3(form)_6](OH)_6R$ (R being the univalent acid residue) with 12, 10, 16, 7 and 2

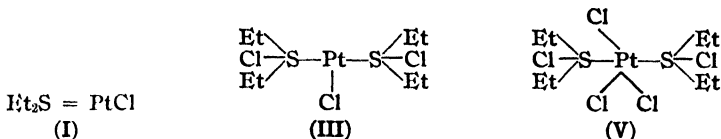

mols. of water of crystn., resp., Mn formate, $[Mn_3(form)_6]form_3 + 2H_2O$, which is decomposed by water and $EtOH$, and basic Al formate $Al(form)_2OH + H_2O$. E. K.

Oxides of iron, chromium and antimony, and the nature of the combination with oxygen. A. SIMON. *Oesterr. Chem. Ztg.* **28**, 195-6(1925).—Just as a part of the H_2O in hydrated oxides may be considered as fixed in position in the space lattice, while the rest has a certain mobility, so can a part of the O in oxides of Fe, Cr, Sb and As be fixed while the remainder is not. A similar condition is observed with higher oxides of U, which tend to change into U_3O_8 . X-ray studies on U-bearing minerals confirm this view. Studies on the isobar of the Fe_2O_3 to Fe_3O_4 transformation indicate that above 1300° a part of the O is in a mobile state. In the CrO_3 - Cr_2O_3 transformation there are indicated compds. Cr_6O_{13} and Cr_7O_{12} (the latter hitherto unknown). With CrO_3 a part of the O is mobile. In the Sb_2O_5 - Sb_2O_3 transformation at 430° there is formed Sb_5O_{13} (hitherto unknown); at 700° this decomposes into Sb_2O_3 and the latter at 910° yields Sb_2O_3 , with no intermediate oxides apparent.

W. C. EBAUGH

Varying valency of platinum with respect to mercaptanic radicals. II. PRAFULLA CHANDRA RAY AND KSHITISH CHANDRA BOSE RAY. *Quart. J. Indian Chem. Soc.* **2**, 178-90(1925); cf. *C. A.* **17**, 1470; **18**, 3558.—By interaction of Et_3S and $PtCl_4$ under various conditions the following compds. were prepd. $(Et_3S)PtCl$ (I), did not m. 250° ; $(Et_3S)_2PtCl_2$ (II) (see below); $(Et_3S)_3PtCl_3$ (III), orange-red crystals, m. 109° ; $(Et_3S)_2PtCl_2$ (IV), yellow crystals, m. 198° ; $(Et_3S)_2PtCl_2$ (V), orange crystals, m. 90° . Six isomeric modifications of II were isolated: (α) golden yellow plates, m. 108° ; (β) pale white crystals, m. 108° ; (γ) greenish yellow crystals, m. 110° ; (δ) colorless needles.

m. 104°; (e) lemon-yellow monoclinic plates, m. 96°; (f) (cf. *C. A.* 17, 1470), m. 77°
Possible structural formulas for I, III and V are as follows:

III may be considered as a mol. compd. of II and IV; on crystn. from boiling EtOH it breaks down into the component mols. Evidence is adduced for the formula $\text{H} \left[\begin{array}{c} \text{Pt} \\ \text{Cl}_6 \\ \text{OH} \end{array} \right] \cdot (\text{Et}_2\text{S})_2 \cdot \text{H}_2\text{O}$ to represent V. Ebullioscopic detn. of the mol. wt. of I in CHCl_3 indicates the formula $[(\text{Et}_2\text{S})\text{PtCl}]_3$. Disodium dithioethyleneglycol and PtCl_4 when refluxed in Et_2O soln. give a brick-red ppt. of the formula $\text{Pt}(\text{C}_2\text{H}_4\text{S}_2)_2 \cdot \text{PtCl}_2 \cdot \text{Et}_2\text{O}$; a similar procedure with MeAc as solvent gives a chocolate-colored ppt. of the formula $2\text{Pt}(\text{C}_2\text{H}_4\text{S}_2)_2 \cdot \text{C}_2\text{H}_4\text{S}_2$.

DONALD W. MACARDLE

Preparation of pure nickel monoxide (NiO). M. LE BLANC AND H. SACHSE. *Z. Elektrochem.* 32, 58-62(1926).—NiO prepd. at different temps. has different colors varying from gray-black to green, accompanied by a varying Ni_2O_3 content (detd. with KI). Heating of NiCO_3 in the air never gives pure NiO; the oxide takes up some O_2 on cooling (Ni_2O_3 up to 1.4%); cooling in dry N_2 yields a pure product with one % water; NiCO_3 in *vacuo* at temps. higher than 280° decomposes to NiO free of higher oxides with less than 0.5% water. If instead of vacuum the decompn. takes place in an indifferent gas dried by CaCl_2 the oxide contains some 5% water.

B. J. C. VAN DER HOEVEN

The constitution of nickel carbonyl and the nature of secondary valence. A. A. BLANCHARD AND WM. L. GILLILAND. *J. Am. Chem. Soc.* 48, 872-82(1926).—The reactions of $\text{Ni}(\text{CO})_4$ with Br, S, O and Grignard reagents are described and indicate that it is a loose association of Ni and CO, either constituent reacting alone with substances with which it would be expected to react were it in the free state, leaving the other constituent uncombined. This supports the claim that $\text{Ni}(\text{CO})_4$ is a compd. in which secondary valence alone is exerted, the primary valences which both Ni and CO are capable of developing remaining dormant. The authors propose a structure for carbonyls in which 4 electrons of each carbonyl group are held in the sheath of the nickel atom and 16 of the Ni sheath are shared, leaving 2 which are put in the polar axis unshared. Such electrostatically self-contained structures can account for the extreme volatility of these complex molecules. CH_2O_2 is formed in small amts. from CO and H_2O in the slow oxidation of $\text{Ni}(\text{CO})_4$.

H. STOERTZ

The transformation and oxidation of the sesquioxide of chromium. L. BLANC AND G. CHAUDRON. *Compt. rend.* 182, 386-8(1926); cf. *C. A.* 19, 1653.—B. and C. try to define the oxidation reactions whereby blue $\alpha\text{-Cr}_2\text{O}_3$ changes in air at 500° to olive-green $\beta\text{-Cr}_2\text{O}_3$. The method was by differential thermal analysis in a Saladin-LeChâtelier app. This change takes place with incandescence at different temps. depending on the atm. and pressure. Both varieties of Cr_2O_3 are oxidized to corresponding α and β -oxides of the compn. Cr_2O_5 and the transformation of the $\alpha\text{-Cr}_2\text{O}_3$ in air at 500° into the $\beta\text{-Cr}_2\text{O}_3$ is hindered by the transformation of the $\alpha\text{-Cr}_2\text{O}_3$ into $\beta\text{-Cr}_2\text{O}_3$ at about 440°. Guignet's green is evidently only finely divided $\beta\text{-Cr}_2\text{O}_3$.

P. B. P

Basic stannous sulfate. C. M. CARSON. *J. Am. Chem. Soc.* 48, 906-11(1926) NaOH soln. of varying concn. was allowed to act upon SnSO_4 in a flask suspended in boiling H_2O and shaken for 1 hr. The resulting mixt. was filtered quickly and the ppt. dried and analyzed. Sn was pptd. as sulfide and weighed as oxide. A curve is given showing variation of SO_4 content with NaOH used, from which it is seen that within 2 regions of alkali variation the ppts. remain approx. const. in compn., indicating 2 definite compds. having the probable formulas: SnSO_4 , SnO and $\text{SnSO}_4 \cdot 2\text{SnO}$ -unknown- H_2O . Methods of analysis are described, with methods of correcting the analyses of incompletely sepd. solid phases for the retained liquid phase.

H. STOERTZ

Researches on the complexes of stannous iodide. T. KARANTASSIS. *Bull. soc. chim.* 39, 43-4(1926); cf. *C. A.* 20, 1039.—The complexes $\text{SnI}_2\text{N}(\text{CH}_3)_4$, $\text{SnI}_2\text{As}(\text{CH}_3)_3$, $\text{SnI}_2\text{NH}_3\text{C}_2\text{H}_5$ and $\text{SnI}_2\text{NHC}_2\text{H}_5$ are obtained from the union of SnI_2 and org. bases contg. I. Such complexes are all of the same type; SnI_2BH and show analogy with the salts of K and NH_4 . Rb and Cs further form salts of the type $(\text{SnI}_2)_2\text{MI}$.

P. B. P

The preparation of mosaic gold. HANS HADERT. *Chem.-Ztg.* 50, 7-8(1926).—

Mosaic gold made by the wet process is of inferior quality; therefore the dry method is preferred. Mix 14 kg. Sn filings with 6.5 kg. of Hg, and heat in an enameled vessel on a sand bath, with const. stirring. An amalgam forms which hardens on cooling. Mix 8 kg. of powdered S and 6.8 kg. NH_4Cl with the amalgam (finely divided), put in glass vessels loosely stoppered with a porcelain cover, and heat gradually in a sand bath until vapors cease coming off (about 4 hrs.), after which heat the bath to redness. Then allow the fire to die down gradually. In the flask are found golden-yellow crystals of mosaic gold. They adhere easily to objects they touch. Usually two grades are sepd from a batch, those in the upper part of the container being of better quality than the others. Mosaic gold is especially adapted for gilding, as it does not tarnish readily. Different shades of mosaic gold are made by varying the proportions of components used.

W. C. EBATUGH

Preparation of disilicon hexachloride. J. B. QUIG AND J. A. WILKINSON. *J. Am. Chem. Soc.* **48**, 902-6 (1926).—The yield of *disilicon hexachloride* obtained by passing Cl over ferro-silicon at 200° was greatly increased by passing the Cl first through SiCl_4 so that vapors of the tetrachloride were present in the gas. A yield of 34.9%, calcd on the basis of the wt. of Si used from the 50% Fe-Si added, was obtained when SiCl_4 was aspirated at the rate of 0.5152 g. per min. If the SiCl_4 is increased beyond this point, the yield is reduced, indicating that the first increase in yield is due to a hastening of the final chlorination and not to a reduction of SiCl_4 by Si. App. and methods of analysis are described.

H. STOERTZ

The action of red phosphorus on iodine in organic solvents. R. N. TRANLER AND F. E. E. GERMANN. *J. Am. Pharm. Assoc.* **14**, 476-7 (1925); cf. *C. A.* **19**, 3440. Red P reacts with I in CS_2 to form PI_3 . The reaction is complete provided sufficient red P is present. If moisture is present the iodide formed reacts with the H_2O yielding HI and P acid, both of which can later be removed from the remaining red P by washing with H_2O . The error in the work of the former experimenters rests in their failure to recognize that a chem. reaction, not adsorption, was the main factor in the removal of free I by red P from the solns. used.

L. E. WARREN

The oxidation of hydrazine. I. Potassium azo-disulfonate. E. KONRAD AND L. PELLENS. *Ber.* **59B**, 135-8 (1926).—The mechanism of oxidation of hydrazine must be studied first on some of its stable derivs. Potassium hydrazine disulfonate is very stable in acid solns. It was oxidized in alk. soln. by KOC with evolution of N_2 . At temps. below 0° the soln. turns yellow and the salting out with KCl ppts. K azo disulfonate $\text{KO}_2\text{SN}=\text{NSO}_2\text{K}$, insol. in H_2O and org. solvents, easily hydrolyzed to $\text{N}_2 + \text{K}_2\text{HSO}_3 + \text{KHSO}_4$. The sym. formula $\text{HSO}_2\text{IINNHSO}_2\text{H}$ should be adopted for hydrazinedisulfonic acid.

G. CALINGAERT

The reaction between hydroxylamine and ferric chloride. A. D. MITCHELL. *J. Chem. Soc.* **1926**, 336-50.—“The rate of reaction after the early stages is directly proportional to the concn. of NH_2OH and to the square of that of FeCl_3 , and inversely proportional to the concn. of ferrous salt and to the square of the H^+ concn. The most probable interpretation is that reaction proceeds by way of an intermediate equil. involving a complex of the type shown: $2\text{Fe}^{+++} + \text{NH}_2\text{OH}^+ \rightleftharpoons \text{Fe}^{++} + 2\text{H}^+ + (\text{NOH, Fe, H})^{+++} \rightarrow \text{N}_2\text{O}$, etc. The abnormal temp. coeff. of 6.5 for a 10° rise would thus be partly due to a more favorable displacement of the equil. ‘Salt effect’ is negative—reaction velocity is depressed by the addn. of indifferent salts.”

F. L. BROWNE

Bismuth compounds. I. B. HEHNER AND A. LIKIERNIK. *Arch. Pharm.* **264, 46-55 (1926).—Constitution of bismuth nitrate and tartrate.** The behavior of $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ in a desiccator over H_2SO_4 of varying concn. was observed *via* van Bencelen, and the resulting data were tabulated. Substituent compds. of Bi nitrate with mannitol,

glycerol and sorbitol were studied analytically, viz.: $\left[\text{Bi} \begin{smallmatrix} \text{ } \\ \text{NO}_3 \end{smallmatrix} \right]^{1/2} \text{mannitol} \left[\text{NO}_3 \right]_2$,

$\left[\text{Bi} \begin{smallmatrix} \text{glycerol} \\ \text{NO}_3 \end{smallmatrix} \right] (\text{NO}_3)_2$ and $\left[\text{Bi} \begin{smallmatrix} \text{sorbitol} \\ \text{NO}_3 \end{smallmatrix} \right] (\text{NO}_3)_2$, likewise solns. of the nitrate in neutral

salts, viz.: $\left[\text{Bi} \begin{smallmatrix} (\text{NO}_3\text{NH}_4)_3 \\ \text{NO}_3 \end{smallmatrix} \right] (\text{NO}_3)_2$, BiONO_3 dulcitol and BiONO_3 mannitol. Of the

tartrates, the following were prepd.: $\left[\text{Bi} \begin{smallmatrix} (\text{OH})_2 \\ \text{NO}_3 \end{smallmatrix} \right] \text{O} \cdot \text{OCCH}(\text{OH}) \text{H}_2\text{O} \left[\text{Bi} \begin{smallmatrix} (\text{OH})_2 \\ \text{C}_4\text{H}_5\text{O}_6 \end{smallmatrix} \right] \text{C}_4\text{H}_4\text{O}_6$

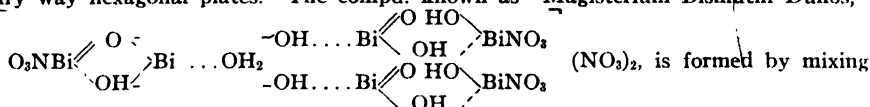

$\text{BiO} \cdot \text{OCHCHOH} \dots \text{BiO} \cdot \text{OH}$
and

$\text{NaOOCCHOH} \dots \text{BiO} \cdot \text{OH}$
basic bismuth nitrate. The first decompn. product of Bi nitrate with H_2O has the for-

II. B. HEPNER. *Ibid.* 55-65.—*Constitution of*

mula $\text{Bi} \begin{array}{c} \diagup \text{O} \\ \diagdown \text{NO}_2 \\ \diagdown \text{OH}_2 \end{array}$ and consists of characteristic scales (very thin striped microscopic plates), which on 8 hrs.' dehydration in a desiccator had rather uniformly the compn. $(\text{Bi}_2\text{O}_3) \cdot (\text{N}_2\text{O}_5)(\text{H}_2\text{O})_{1.9}$. The H_2O loss was unaccompanied by any loss of HNO_3 , the ratio of $\text{Bi}:\text{HNO}_3$ remaining 1:1. The compd. $\left[\text{O}_2\text{NBi} \begin{array}{c} \diagup \text{O} \\ \diagdown \text{OH} \end{array} \right] \text{BiOH} \left| \text{NO}_3 \right.$ was obtained by

heating equal parts of Bi nitrate and H_2O on the H_2O bath until the scales change into heavy crystals, or on protracted standing of the scales with the mother liquor (1 part of nitrate to 11 parts of H_2O), or finally by continued action of HNO_3 contg. less than 6% N_2O_5 . Prepd. in the wet way the crystals are microscopically monoclinic, in the dry way hexagonal plates. The compd. known as "Magisterium Bismuthi Duflos,"

1 part of Bi nitrate with 24 parts of H_2O , and dissolving this mixt. in 120 parts of H_2O , or by heating 1 part of the nitrate with 24 parts of H_2O at 75° until the ppt becomes cryst. It is also formed by allowing the scales to stand for about a year covered by H_2O . When formed slowly at the ordinary temp. large rhombs are obtained, at higher temp. small rectangular crystals. On drying over H_2SO_4 , the salt loses neither H_2O nor HNO_3 . The final degradation product by the action of H_2O on Bi nitrate is

$\text{O}_2\text{NBi} \begin{array}{c} \diagup \text{O} \\ \diagdown \text{OH} \end{array} \text{BiO}$, formed by digesting 1 part of Bi nitrate with 24 parts of H_2O on the H_2O bath in 2-hr. periods, rejecting the H_2O at the end of each period. It is a cryst powder of hexagonal aggregates. W. O. F.

Ammonium carbonates. C. BONNIER. *Ann. chim.* 5, 37-94 (1926).—The equilibria were studied by disson. tension of dry NH_4HCO_3 (a), and the tension of its aq solns. (b), both by static methods. (a) Equilibria were reached in 2.5 hrs. at 60° and 6 days at 25° . $\log p = 27.5 - (7680/T)$. The heat of formation, L , of NH_4HCO_3 from CO_2 , NH_3 and H_2O was calcd. as 38.3, agreeing fairly well with the value, 40.5, from other data. By using the latter value $\log K = 70.98 (20250/T)$, where $K = p_1 p_2 p_3$, the product of the partial pressures of the components. From this formula $K_{20} = 6.5$, $K_{25} = 20.7$, $K_{30} = 63.5$ (b) The effects of concn., temp., and vol. of the gas phase were studied. With increasing H_2O the pressure rises rapidly to 4.5 parts (satn. at 20°) and then decreases gradually. At 25° , 1 g. dissolves in 3.9 g. H_2O ; and at 30° in 3.5 g. With increasing gas space the pressure decreases slightly. With excess of NH_3 at 20° the pressure decreases to 3.3 cm. at 0.215 part $\text{NH}_3(\text{NH}_4)_2\text{CO}_3$, and then increases, the curve being parallel to but slightly below that for NH_3 in H_2O . The combination to $(\text{NH}_4)_2\text{CO}_3$ is not complete, since the minimum is higher than the pressure of H_2O , 1.7 cm.; and CO_2 exists in the gas phase even with excess NH_3 , since the pressure varies slightly with the vol. of the gas phase. From theoretical consideration for which the original must be consulted, the formula $P = 1.7 + w\sqrt{aK}/\sqrt{q(V + bq)}$ was derived, in which P is the total pressure, w is the wt. of NH_4HCO_3 dissolved, q is the wt. of H_2O in the soln., V is the vol. of the gas phase, K is the equil. const., and a and b are functions of the solubilities of CO_2 and NH_3 , resp., in the soln. The observed pressures agreed well with those calcd. by this formula. It is shown that H_2O does not act upon NH_4HCO_3 merely as a solvent, but as a reagent with high affinity for NH_3 . liberating CO_2 . A. W. FRANCIS

The action of hydrogen and water on phosphorus at high temperatures and under pressure. (Preliminary paper.) V. IPATIEV AND V. NIKOLAIEV. *Ber.* 59B, 595 (1926).—When white P is heated with H in a closed tube under 360° , PH_3 forms. In the presence of water also H_3PO_4 is obtained, while with water alone in the absence of H, H_3PO_4 and PH_3 are obtained. The formation of the latter from P and H_2O starts at about 290° and 40-50 atm. and is indicated by a break in the temp.-pressure diagram. A *cryst. purple modification of P* is obtained in the presence of water when the temp. is raised to 248° under a pressure of 48 atm. and then allowed to drop quickly. The purple P is sol. in CS_2 . Over 216° and 89 atm. the *black crystalline P* forms, which is insol. in CS_2 . EMIL KLARMANN

Optically active tripyrocatechol-arsenic acid. ARTHUR ROSENHEIM AND WILLIAM PLATO. *Ber.* 58B, 2000-9 (1925).—The constitution suggested by Reihlen (*C. A.* 19,

2307) for tripyrocatechol-arsenic acid indicated the possibility of splitting the ordinary acid into optically active isomers. For the *l*-form, sepd. as the cinchonine salt, an av. mol. rotation of about -2400 was found for several compds. of the active anion. Corresponding values were found for the *d*-form, sepd. as the quinine or the cinchonidine salt. Optical activity could be explained only by the assumption that the pyrocatechol was bivalent in the complex anion. Observed values for optical rotation of the free *d*-acid, the free *l*-acid, and about a dozen salts of the *d*-, *l*- and *dl*-acids are given. A slow racemization of the active anion was noted in neutral soln; this was greatly favored by H^+ and repressed by OH^- .

Nitrosiselenic acid. JULIUS MAYER AND WALTER GULBINS. *Ber.* 59B, 456 (1926).—The purpose of the paper is the prepn. of a Se analog of nitrosulfuric acid $(HO)ON \cdot SO_3H$. When nitrosyl-selenic acid $SeO_2(O \cdot NO)(OH)$ is dissolved in $H_2SeO_4 + H_2O$ and a droplet of Hg is added, the soln. becomes blue. It is decolorized by the addn. of oxidizing agents or water with formation of NO. The blue color is intensified by the addn. of a Cu-selenate soln. The agreement in the behavior of the S and Se compds. suggests the formula $(HO)ON \cdot SeO_2H$ for nitrosiselenic acid. The same compd. forms, when a soln. of $NaNO_2$ in strong H_2SeO_4 is shaken with metallic Hg.

Caro's reagent. REECE H. VALLANCE. *J. Soc. Chem. Ind.* 45, 66T (1926).—Twenty g. of $K_2S_2O_8$ were triturated with 13 cc. concd. H_2SO_4 in the cold, dild. in ice- H_2O , and neutralized at 0° with K_2CO_3 soln. The resulting soln. was evapd. in vacuum at 50° , yielding nearly *N* solns. of $KHSO_5$.

Volumetric determination of calcium in mineral substances containing phosphoric acid, magnesium, iron and aluminum. R. MELLET. *Schweiz. Apoth. Ztg.* 63, 377-80 (1925); cf. *C. A.* 19, 2180; Canals, *Ibid.*—Reply to criticism by Canals. An inadvertent omission caused the apparent error. The sepn. of Ca and Mg oxalates by boiling H_2O as recommended by Canals (cf. *C. A.* 16, 1615, 3044) ignores the soly. of CaC_2O_4 in H_2O at $95^\circ = 0.0014\%$ (Richards, 1901); still, the washing of the Cu ppt. with hot H_2O may lead to correct results by compensation of errors.

S. WALDBOTT

Modification of Knop's method for the titration of iron. O. ROTHE AND A. P. SOBRINHO. *O. Brasil Tech.* 2, 79-90(1925).—A discussion of the $K_2Cr_2O_7$ titration of Fe^{++} with diphenylamine as indicator. W. T. H.

Determination of chromium in chromite. E. DITTLER. *Z. angew. Chem.* 39, 279(1926).—In the $KMnO_4$ method for the detn. of Cr it is often recommended to use an empirical value for the value of 1 cc. of $KMnO_4$ in terms of Cr. A careful comparison of values obtained in some 19 analyses with values obtained by the iodometric method shows that the true stoichiometric ratio is practically correct. Possibly increasing the $KMnO_4$ value 0.3 of 1% is justifiable but certainly the 5% increase recommended by some is altogether wrong. W. T. H.

Volumetric determination of nickel in alloys. OSKAR VON GROSSMANN. *Metall u. Erz* 22, 157-9(1925).—Dissolve 1 g. of alloy in 20 cc. of 7.5 N HNO_3 . Dil. to 150 cc. and remove Cu and Pb by electrolysis. Dil. to 500 cc. in a measuring flask and mix. To an aliquot part, add 5 cc. of 25% NH_4 tartrate and 25 cc. of NH_4OH . Add enough 0.5% KCN to destroy the green color and 10-15 cc. of NaOH to keep Zn in soln. Add 2 drops of 20% K_2S_8 soln. as indicator and titrate with KCN until the red color changes to yellow. C. G. KING

Phenylarsonic acid as a reagent for the determination of zirconium and thorium. A. C. RICE, H. C. FOGG AND C. JAMES. *J. Am. Chem. Soc.* 48, 895-901(1926).—Phenylarsonic acid, $C_6H_5AsO(OH)_2$, forms a very insol. compd. with Zr and pptn. results in the presence of considerable mineral acid. The corresponding Th salt is insol. in fairly strong AcOH solns. Detailed directions are given for the detn. of Zr in the presence of Fe, Al, Ti, Th, elements of the cerite group, U, Bi, Co, Mn, Co, Ni, Co, Zn, alkalies and H_3PO_4 , as well as for the detn. of Th in the presence of rare earths, e. g., in monazite sand. W. T. H.

The separation of germanium. I. WADA AND S. KATO. *Sci. Papers Inst. Phys. Chem. Research* 3, 243-61(1925).—Detailed directions are given for the detection of Ge in the presence of other elements which are likely to interfere. By means of H_2S first in acid soln. and later in ammoniacal soln. it is possible to remove most other elements that are likely to interfere with the Ge test. Small quantities of Se and As are likely to escape pptn. by H_2S . Distn. with HBr and Br_2 causes complete volatilization of $GeBr_4$ but Se and As also distil. From the aq. soln. of the distillate, Se can be pptd. by SO_2 . Then, by adding HNO_3 and evapg. to dryness, a residue is obtained which yields volatile GeF_4 when heated with HI and Cl_2 and, under these conditions, no As is distd. The Ge in the aq. soln. of the distillate will give a white ppt. of GeS_2 , after the Cl_2 is driven off by a stream of air and H_2S is introduced. The ppt. on ignition yields GeO_2 . W. T. H.

Volumetric determination of uranium, vanadium, copper and iron in uranium ores. A. S. RUSSELL. *J. Soc. Chem. Ind.* 45, 57-60T(1926).—(I) To the soln. contg. these elements, add H_2SO_4 enough to make the concn. of acid about 6 N. Shake with 3% Zn amalgam until the lavender color due to bivalent V is not further changed in intensity, decant the reduced soln. into a flask, wash the amalgam and allow 30 sec. for the oxidation of tervalent U to the quadrivalent uranous condition. Pour the soln. into an excess of 0.1 N $KMnO_4$, heat to 80° and titrate the excess permanganate with standard uranous soln. Assume the oxidation by $KMnO_4$ to be of V^{II} to VV , U^{IV} to UVI and of Fe^{II} to Fe^{III} . (IIa) To the hot soln. which has just been titrated with uranous soln., add NH_4OH until a permanent ppt. just fails to form. Cool to room temp., add 5 g. KI and a suspension of some freshly pptd. Cu_2I_2 to act as catalyzer. After 3 mins. titrate the liberated I_2 with $Na_2S_2O_3$. This gives the Fe and V, each being reduced 1 valence. (IIb) To the original soln. which has been fully oxidized but not treated with Zn-Hg, add KI and continue as in (IIa). This gives the Fe, V and Cu, each element experiencing 1 valence change. (III) Acidify and oxidize another portion of the original soln. as in (I), add H_3PO_4 and a few drops of a satd. soln. of diphenylamine in concd. H_2SO_4 and titrate with standard $FeSO_4$ soln. to the disappearance of the blue. This gives the V, reduced from a valence of 6 to 5. In the absence of V, the analysis is simpler. By the first procedure, the U and Fe are detd., by IIa the Fe alone and by IIb the Cu and Fe. Procedure III is unnecessary in this case. To test a ppt. of UO_2 to see if $1/2$ of the U is in the quadrivalent condition, add 0.6 g. of the oxide to 150 cc. of 6 N H_2SO_4 at 80° and an excess of $KMnO_4$ over that needed to oxidize the quadrivalent U to the hexavalent condition. When the oxide has all dissolved, titrate the excess $KMnO_4$ with standard $FeSO_4$ soln. W. T. H.

Determination of gold dissolved in mercury. G. TAMMANN AND K. KOLLMAN. *Z. anorg. allgem. Chem.* 151, 269-70(1926).—When Zn is deposited electrolytically on Hg contg. Au, the e. m. f. of the Hg electrode is changed but slightly until enough Zn

has been added to form AuZn, then there is a sudden change in cathode potential. For quantities of Au up to 0.005%, this furnishes a means of detn. W. T. H.

Spectroscopic detection of minute quantities of mercury. J. J. MANLEY. *Proc. Phys. Soc. London* 38, 127-8(1926).—Necessity arose for testing spectroscopically for traces of Hg in vertically placed U-tubes forming parts of permanent app. To accomplish this, external electrodes were provided by partially immersing the tubes in water contained in insulated beakers and wires from the high potential terminals of an induction coil activated by a 6-volt accumulator were lead into each beaker. When the coil was activated, the evacuated U-tubes, in one of which the test was to be made, were brought to a bright glow, like an ordinary spectrum tube. An end-on view of the glow within the excited tube could be obtained with the aid of a totally reflecting prism formed upon one of the limbs of the U-tube. The light was thus reflected horizontally and received in the usual way by a Hilger wave-length spectrometer.

W. T. H.

Microchemical estimation of very small amounts of mercury. E. J. HARTUNG. *Sci. Australian* 29, 509(1924); *J. Inst. Metals* 33, 427.—The Hg is deposited from a suitable soln. on a clean Cu strip. This is then heated in a tube fitted with a capillary extension, which is cooled by a wet thread. The condensed globules are measured under a microscope and their total mass is calcd. In this way as little as 0.001 mg. can be estd.

H. C.

Electrolytic separation of copper and cadmium. A. JILEK AND J. LUKAS. *Chem. Listy* 20, 18-21(1926); cf. *C. A.* 19, 3231.—Cu free from Cd can be deposited by a current of 1 amp. at 4 v. in a soln. contg. 15 cc. concd. HNO_3 , 6 g. tartaric acid and 15 g. 40% HF per 100 cc.

F. C. KRACEK

Silver determination in retort ash (zinc distillation). H. HASSREIDTER. *Metall u. Erz.* 22, 403-4(1925).—A suitable Pb button can be obtained by melting 5 g. of the ash with 25 g. of mixed borax and soda and enough KNO_3 to give a 20-30 g. button. Or, 15 g. of ash can be fluxed with 75 g. of PbO_2 , 10 g. of sand and 45 g. of soda, in which case the button will weigh about 60 g. Cupel and finish the assay as usual. C. G. K.

Electrolytic determination of moderate amounts of arsenic. J. MOIR AND J. S. JAMIESON. *J. South African Chem. Inst.* 8, 16-8(1925).—The app. is a modification of Thorpe's electrolytic app. with substitution of the generator cell by a narrow cylinder, and of the porous pot by an alundum crucible. A Cd electrode is used (activated by reversal of the current and subsequent deposition of porous Cd on restoring the normal direction) and Pt anode. The pressure of the anode liquid (1.5- H_2SO_4) prevents outward diffusion of the arsenical liquid. The cross tube is filled with Pb acetate cotton wool, and the gas exit connected with AgNO_3 tubes; the contents of these are titrated with dil. I soln. after addn. of a large excess of KI.

B. C. A.

Determination of small amounts of selenium in sulfide ores. MAX SCHMIDT. *Metall u. Erz.* 22, 511(1925).—Treat 10-20 g. of ore with aqua regia. Heat 10 mm., add 10 g. of NaOH and evap. to dryness. To the residue add enough concd. HCl to decompose the nitrates. (If a red residue remains repeat the treatment.) Dil., filter off the siliceous residue and in the filtrate remove Pb as PbSO_4 . To the filtrate from the PbSO_4 , add HCl and sat. with H_2S . Filter and digest the sulfides with $(\text{NH}_4)_2\text{CO}_3$ soln. to remove As. Dissolve the residual ppt. in aqua regia and ppt. Se with 10% SnCl_2 in concd. HCl. The method serves for the detn. of as little as 0.0001% Se.

C. G. KING.

The analysis of antimony pentasulfide. LOTHAR HOCK. *Kautschuk* Dec., 1925, 11-3.—In analyzing com. Sb_2S_5 it will be found advantageous to convert the substance to black Sb_2S_3 *in vacuo* rather than in a current of CO_2 . Place the Gooch crucible contg. the Sb_2S_5 (extd. with CS_2) at the bottom of a glass tube which fits loosely in an outer slightly longer tube (25 cm. long, 45 mm. internal diam.). Close both tubes at the bottom and immerse to about 0.5 their depth in an elec. oven at 300°, or in a bath of boiling BzOH . The outer tube has a ground-glass stopper from which a tube leads to a vacuum pump. On gradually heating, the sulfide decomps. and the S liberated sublimes in the cold upper portion of the inner tube. The Sb_2S_3 usually becomes of const. wt. in about 35-40 min. The approx. compn. of the original material ($\text{Sb}_2\text{S}_5 + \text{S}$) can be calcd. from the wt. of S extd. by CS_2 from the original material, the final wt. of Sb_2S_3 and the loss of wt. by decompn. It can be shown in this way that there must exist a compd. Sb_2S_5 and that contrary to Kirchhof (*C. A.* 15, 1469) Sb_2S_4 is not the only sulfide above Sb_2S_3 .

C. G. DAVIS

Report of sub-committee on determination of water. W. H. FULWEILER. *Proc. Am. Soc. Testing Materials* 25, Pt. I, 416-23(1925).—A discussion of the detn. of H_2O in different materials, bringing out the advantages of the method consisting in distn.

in the presence of a solvent (Method D 95-24), suggesting the possibility and advisability of extending its use to other classes of materials than those for which it is used at present. A bibliography of 56 references is given in connection with the method. A. P.-C.

Rapid method for the determination of moisture content. J. TAUSZ AND H. RUMM. *Z. angew. Chem.* 39, 155-6 (1926).—This ingenious method is suitable for the detn. of moisture in all sorts of materials, such as wheat flour, rye flour, white bread, yeast, butter and petroleum. It is based upon the principle of distg. with a less volatile liquid which has been used by others but the liquid used and the app. recommended represent improvements. The substance is mixed with considerable $C_2H_2Cl_4$ and heated in a dry flask. The distillate passes through a fractionating tower, which serves at first to condense all the $C_2H_2Cl_4$, and the steam is caused to condense and pass through a capillary into a gas buret contg. $C_2H_2Cl_4$ as confining liquid. The water, being of less d., floats upon this liquid. The distn. is continued, with gradually increased temp., until clear $C_2H_2Cl_4$ is obtained as distillate, the lack of turbidity showing that all water has been removed. Then the water is pushed up, by the leveling device, into a narrow measuring tube. The results of numerous analyses indicate that the method is very suitable for the analysis of substances which are easily decompd. and partially burned when heated directly. W. T. H.

New method of silicate analysis. ROBERT SCHWARZ AND ADOLF SCHINZINGER. *Z. anorg. allgem. Chem.* 151, 214-20 (1926).—It is proposed to substitute Li_2CO_3 for Na_2CO_3 or $NaKCO_3$ in the analysis and after such a fusion, even the alkalis can be detd. in a single sample. The analysis proceeds in the conventional way up to the detn. of Mg. Owing to the slight soly. of Li_3PO_4 it is not advisable to attempt pptn. of $Mg-NH_4PO_4$ in the presence of Li. Pptn. of $MgNH_4AsO_4$ and subsequent iodometric detn. of the As proved satisfactory. For the detn. of alkali it is necessary to remove the Li which is best accomplished by adding $(NH_4)_2HPO_4$ and then, since $LiPO_4$ is appreciably sol. in NH_4 salts., evap. down to dryness and gently ignite. After this treatment the $LiPO_4$ is insol. in alc. After filtering it off, the phosphate can be removed by adding $FeCl_3$ and carrying out the basic acetate sepn. The alkalis can then be detd. as usual. The results obtained in the analysis of an Al silicate showed good agreement for SiO_2 , Al_2O_3 , MgO , Na_2O and K_2O with analyses carried out after Na_2CO_3 fusion and by the J. L. Smith method. W. T. H.

Confining liquids for gas analysis. F. G. HOFFMANN. *Feuerungstechnik* 14, 98-101 (1926).—Soln. of the gases, especially CO_2 , is an important source of error in gas analysis. Satg. the liquid with the gas is not satisfactory, since the gas compn. changes during the analysis. Of 19 liquids examd., a 22% soln. of pure NaCl dissolved the least CO_2 ($1/3$ as much as pure water). Acidified water is no better than pure water. ERNEST W. THIELE.

Sampling and examination of mine gases and natural gas. G. A. BURRELL, F. M. SEIBERT AND G. W. JONES. *Bur. Mines, Bull.* 197, 108 pp. (1925).—A revision of *Bull.* 42 of like title (cf. *C. A.* 8, 1671). Minor changes have been made in the construction and operation of various app. for the exact analysis of mine gases, the detn. of CH_4 in mine air, etc., and in the *Bur.* of Mines standard Orsat app. (known by the trade name of "Burrell gas app.," cf. *C. A.* 20, 846). Detailed working sketches of all parts of these app. and exact directions for their use are given. The section on sampling has been considerably revised, that on analysis by means of the gas interferometer has been enlarged, sections on the I_2O_5 and pyrotannic methods for CO have been added and numerous other addns. and revisions have been made. W. B. PLUMMER.

Determination of carbon monoxide in hydrogen. P. SCHUPTAN. *Z. anorg. Chem.* 39, 276-8 (1926).—CO present in H_2 can, in the absence of O_2 , be detd. in quantities up to 10% by measuring the contraction that results on passing the gas over $Ni-Al_2O_3$ catalyzer heated to 200-300°. CO unites with $3H_2$ to form CH_4 and 3 mol. of H_2O so that the contraction is 3 times the vol. of the original CO. The preparation of the catalyzer is described in detail. The reaction does not take place satisfactorily if the temp. is too high or the CO content greater than 10%. W. T. H.

Analysis of a mixture of unsaturated gases. A. F. DOBRYANSKII. *Petroleum. Domain* 1925, 565-73.—The gases with a double bond contained in the products of pyro-genetic decompn. of petroleum consist chiefly of ethylene, propylene, isobutylene and erythrene. The method of analysis of these gases devised by D. is based on the selective soly. of unsatd. hydrocarbons in H_2SO_4 of different concns. The easiest to dissolve is isobutylene, next come erythrene, propylene and ethylene in this order. The acid contg. 83-84% of the monohydrate practically ceases to dissolve ethylene in the absence of strong agitation; for propylene the limiting concn. of the acid is 63.61% of H_2SO_4 , for isobutylene 45%. α - and β -Butylenes are sparingly sol. and in this

spect resemble propylene; almost the same holds true for erythrene. The app. used is Hempel's buret and pipets. Three pipets are filled, resp., with H_2SO_4 of 63–64%, 83–84 and 100% monohydrate (the latter may contain 2–1% of SO_3 in soln.). It is also necessary to have 1 pipet with alkali soln. for absorption of vapors of SO_3 and 1 pipet with Br water (200 cc. water, 10 g. KBr and 5 g. Br) to det. the general contents of unsatd. hydrocarbons. The dry gas is introduced into the pipet contg. the weakest acid and kept in contact with the acid until the absorption ceases. The change of vol. is noted and the residual gas is introduced into the next pipet. If the original vol. is V , that after treatment with 64% acid a , after treatment with 84% acid b , and after treatment with 100% acid and with alkali is c , the vol. of isobutylene will be $V-a$, the vol. of propylene $a-b$, the vol. of ethylene $b-c$, the vol. of satd. hydrocarbons and air c . The results obtained differ from the true values by only 0.2–0.4 cc. B. N.

Quantitative determination of erythrene. A. F. DOBRYANSKII. *Petroleum Domain* 1925, 574–7; cf. preceding abstr.—When using the method described in the previous abstract erythrene will be partly dissolved in the acid of the same concn. that dissolves isobutylene. The inconvenience caused thereby is not very great, as erythrene is seldom contained in petroleum gases in amts. greater than 2–1%. For the determination of erythrene D. proposes the following method based on its transformation into the dibromide. The gas is introduced into an air-tight app. contg. a soln. of KBr and H_2SO_4 in water; then a weighed quantity of KBrO_3 is made to react with the liquid: $\text{KBrO}_3 + 6\text{KBr} + 3\text{H}_2\text{SO}_4 = 3\text{K}_2\text{SO}_4 + 3\text{H}_2\text{O} + \text{KBr} + 3\text{Br}_2$. Br is evolved and combines with the unsatd. gases forming dibromides with ethylenes and tetra bromides with diethylenes. A sufficient quantity of KI is introduced in order to bind the excess of Br, and the I set at liberty is titrated by means of a standard thiosulfate soln. Knowing the total quantity of the unsatd. hydrocarbons by the method given in the preceding abstract it is easy to calc. the amt. of the ethylenic hydrocarbons. Examples of calcs. and a figure of the app. are given together with a detailed description of the operating method. About 2½ hrs. are required for the analysis and the precision attained is 0.9% of the theoretical. BERNARD NELSON

Determination of small quantities of alcohol and ether vapors in the presence of one another. E. v. SOMOGYI. *Z. angew. Chem.* 39, 280–1 (1926).—The vapors are passed first through a tube contg. 100 cc. of 9 N H_2SO_4 , which absorbs the alc. but not the ether. The gas is then passed through a mixt. of 50 cc. N $\text{K}_2\text{Cr}_2\text{O}_7$ and 50 cc. of concd. H_2SO_4 , which at once oxidizes the ether to acetic acid. The excess of $\text{K}_2\text{Cr}_2\text{O}_7$ can be detd. iodometrically. For the alc. detn. take 25 cc. of the contents of the first tube, 50 cc. of 0.1 N $\text{K}_2\text{Cr}_2\text{O}_7$ and enough 18 N H_2SO_4 to make exactly 100 cc. After 6 hrs. det. the excess dichromate iodometrically. Or, after heating 2 hrs. at 60° in a closed flask, the oxidation of the alc. can be regarded as complete. W. T. H.

D. E. SHARP

Experimental investigation of the mixing of potassium and sodium feldspars. E. DITTLER AND A. KÖHLER. *Anz. Akad. Wiss. Wien* 61, 101-2(1924).—D. and K. subjected 0.02 mm. sections of perthite, micropertthite, granulite, cryptopertthite and antipertthite on Pt to a temp. of $1000 \pm 25^\circ$ for 500 hrs. or more in an elec. resistance furnace. Before heating the orthoclase and albite lamellas of a section of micropertthite showed extinction angles of 4.5° and 19° . After heating, the extinction became almost uniform, 6° and 8° . The original micropertthite has the properties of an anorthoclase. The other feldspars reacted similarly. Antipertthite contg. 15-20% anorthite showed only slight changes at the edges of the orthoclase inclusions. The fact that albite and orthoclase form mixed crystals probably has a bearing on the ease of diffusion.

E. R. SCHIERZ

Behavior of feldspars at high temperatures. E. DITTLER AND A. KÖHLER. *Anz. Akad. Wiss. Wien* 61, 153-4(1924).—A section || (010) of perthite, of which the microcline contained 7% albite, the plagioclase about 7.6% K feldspar and 2.9% anorthite, showed an extinction angle of microcline lamellas with respect to cleavage cracks = 6.5° ; to the albite lamellas, $20 \pm 1^\circ$. After having been heated to 1000° (cf. preceding abstract) the extinction angle for both was the same as that of the K feldspar, 6° . In some areas where the reaction was not quite complete readings of $11-13^\circ$ were obtained. In sections (001) the characteristic grating structure had disappeared. Sections || (001) of microcline and amazon-stone showed a similar loss of grating structure. This is the result of a rearrangement of the twin lamellas, thereby approaching the higher degree of symmetry exhibited by the orthoclase. In the case of the plagioclase of zonal structure with anorthite content of 20-70% no diffusion is evident even after the high temp. is maintained for 1000 hrs.

E. R. SCHIERZ

Crystallographic investigation of diopside from Saulera, Val d'Ala. M. LUCIANO. *Mem. accad. Lincei* [v] 14, 886-98(1924).—Measurements of crystals of diopside from Saulera give: $a:b:c = 1.0931:1:0.5892$, $\beta = 105^\circ 47.5'$, $d = 3.289$. Contrary to Striiver's statement, these crystals differ distinctly from those of Testa Ciarva.

B. C. A.

Structure of kaolin. Theory of the structure of silicates. M. DOMINIKIEWICZ. *Roczniki Chem.* 5, 252-90(1925).—The space configuration of quartz is, on the basis of its crystal form, of its property of rotating the plane of polarized light, and of the tendency of oxy-Si compds., e. g., silicoformaldehyde, to form rings contg. 6 Si atoms, assumed to consist of spirally disposed rings each contg. alternately 6 Si and 6 O atoms. On this assumption, the structural formulas of various silicic acid derivs. are deduced. The difference between ortho- and meta-silicates depends only on different quant. relationships between the metal and silicic acid, with the probability that for salts of bivalent metals 2 silicic acid nuclei are joined by the metal. For the aluminosilicates only this type of formula can be considered, and the structure of semi-hydrated kaolin, $\text{H}_{24}\text{Al}_2\text{Si}_2\text{O}_{36}$, contg. 4 silicic acid nuclei joined by $-\text{O}-\text{Al}-\text{O}-$ groups is given. From this follows directly, by hydration, the structure of kaolin. This hydration is an ionic reaction, taking place at the 8 $-\text{Si}-\text{O}-\text{Al}-$ groups of the 2 inner satd. rings, and at the 4 free $-\text{Si}-\text{O}$ groups in the 2 outer unsatd. rings. At these 8 inner hydration points various other addn. processes may occur, giving rise to other minerals connected genetically with kaolin, such as margarite, prismatine, nephelite, etc.

Platinum: Its uses and production. E. M. WESTON. *S. African Mining Eng. J.* 34 [II], 179-80(1923); *J. Inst. Metals* 33, 500.—Statistics of production and brief notes of the use of Pt in industry. H. G.

The absorption of gases by silver and the spurt and the homogeneity of solid silver. W. STAHL. *Chem.-Ztg.* 49, 675-6(1925).— O_2 alone is sol in Ag. To prevent the spurt and obtain a homogeneous ingot, S suggests the addn. of a few hundredths of 1% of Al. This removes O_2 and leaves only minute traces of Al in the Ag ingot. G. C.

Studies in slag formation. HERBERT LANG. *Eng. Mining J. Press* 121, 485-90 (1926).—All other bases than Fe have to be satisfied fully before any Fe whatever becomes scorified and enters the pyritic slag. In converter slags as much as 30% magnetite has been found. Al_2O_3 is thought to act either as an acid or base. It should be avoided in fluxes as it has a bad influence in making the slags less fusible and requiring more fuel. Neglect of this principle has caused many failures in smelting. H. C. P

Leaching copper mat and speiss with nitric acid. SIXT. *Chem.-Ztg.* 49, 943 (1926).—Mat contg. Cu 35, Pb 45, Sb 1.5, Sn 1, S 14% and traces of Fe was pulverized and treated with a little more HNO_3 than required for soln. of the metals. The insol. residue contained practically all the Pb, Sn and Sb, but Cu in very small amounts. From the filtrate, with HNO_3 to the extent of 50 g. per liter, Cu was deposited on the Pt cathode, Pb sepg. on the anode as PbO_2 . Magnetite anodes were not suitable. Speiss contg. Sb 18, Sn 8, As 37, Cu 20 and Pb 51% also appears suitable for treatment as above. The Pb is sepd. by H_2SO_4 or by fractional crystn. of the nitrates. Upon electrolyzing the nitrate soln. in HNO_3 , Cu is pptd. practically free from As. If the concn. of H_3AsO_4 becomes too great, pptn. by lime is indicated. W. C. EBAUGH

The roasting of copper concentrate. A. T. FRV. *Chem. Eng. Mining Rev.* 18, 141-4(1926).—Two of the chief requirements in the roasted Cu concentrate are high soly. of Cu and low soly. of Fe. The temp. should not be allowed to rise above $900^\circ F$. It is during the burning stage; otherwise an insol. CuFe forms to a serious extent. It is probable that in the part of the furnace occupied by the burning stage the clearance between arch and hearth should be at least double, and perhaps more, that of the finishing stage. Another suggestion is to make the charge and gases pass through the furnace in the same direction. H. C. PARISH

Combustion in the open-hearth furnace with special reference to automatic control. K. HUSSENER. *Trans. Am. Inst. Mining Met. Eng.* Feb., 1926, No. 1568-C, 32 pp.; *Blast Furnace & Steel Plant* 14, 162-8(1926).—As results with the thermocouple for

low range temps. and with optical or radiation pyrometers for high temps. are not strictly accurate in drawing up heat balances, this investigation was conducted with a radiation-protected pyrometer. A large no. of exact heat balance sheets under varying conditions are necessary. Preheating temps. for the present type of checker chambers are naturally low, and on new construction particular care should be taken to increase the size of the chamber and to obtain equal distribution. Open-hearth furnace results depend upon the amt. of gas completely burned for a given period and on as low an excess of air as is possible. Forced-draft and induced-draft fans and equipment with automatic combustion control are necessary.

W. H. BOYNTON

Manufacture of iron and steel in Sweden. L. NORDENFELT. *J. Chem. Met. Soc. S. Africa* 25, 315-28(1925).—The height of Swedish charcoal blast furnaces is 50-60 ft. and the max. internal diam. is 10 ft. Coke blast furnaces are 65 to 95 ft. high and 20 to 30 ft. internal diam. The 24-hr. pig-Fe output for charcoal furnaces is 18 to 20 tons and in exceptional cases 45 to 50. For coke furnaces it is 350 to 800. The use of charcoal as blast-furnace fuel is characteristic of the Swedish Fe industry. This has an important bearing on the quality of the pig Fe. The small amt. of ash that comes from charcoal only contains 0.004% S, 0.003% P and about 10% H₂O. The CO₂-reducing capacity of coke is at the best only 1/2 that of charcoal. The wt. of coke is 27 lbs. per cu. ft. as against 9 lbs. for charcoal. Fe dropping down in front of the tuyères in a coke furnace and collected in the hearth contains more O than Fe made in a charcoal furnace. Swedish Bessemer steel is made entirely by the acid process. Blowing is stopped at 0.65% C which assists in splitting up FeO at the high temp. from oxidation of Mn and Si. In the Siemens-Martin open-hearth process as used in Sweden, wood gas is used as fuel rather than coal gas, thus minimizing S contamination from the fuel. **Discussion.** *Ibid* 26, 65-6(1926).—The CO₂ varied from 0.76 to 1.7% and the CO was found to be about 36% in samples of gas drawn off at 5-day intervals from a tuyère from which the blast had been shut off and the nose of the tuyère closed with clay. These figures refute the statement that an oxidizing layer exists. It is suggested that instead the presence of FeO in pig Fe may be due to particles of refractory oxide which have been present in the charge and have resisted reduction in their passage through the furnace.

Pig iron mixers. E. LEPEVRE. *Rev. métal.* 23, 82-91(1926).—An address reviewing standard present-day practice.

A. PAPINEAU-COUTURE

The production of iron from silicates and pyrite. G. TAMMANN AND G. BÄTZ. *Z. anorg. allgem. Chem.* 151, 129-39(1926).—By heating a mixt. of finely powd. hornblende (6.5% Fe) and powd. charcoal directly to 1400°, 82.3% of the Fe is reduced to metal. This recovery can be increased to 92.5% if the mixt. is first heated for some time at 600°, in order to free the charcoal from gas. An addition of 5% lime increases the yield of metallic Fe to 95.8-99.1%. The Fe in basaltic rocks that are rich in silica is reduced to a much less extent; the reduction, however, proceeds slowly after an extended heating. Fe₂O₃, Fe₃O₄ and FeO react with quartz at about 950°. Fe₂O₃ and Fe₃O₄ apparently do not combine directly with SiO₂, but after some FeO (which, in the solid state, readily combines with SiO₂) has first formed, the Fe₂O₃ is dissolved in the silicate melt. It is shown that of six Fe silicates, prep'd. in a graphite tube, with increasing concns. of SiO₂, the orthosilicate was strongly reduced by H₂ at 850°. With increasing concns. of SiO₂, the relative amts. of reduced Fe obtained are large, which explains the permeability of quartz to H₂ at high temps. The reduction of pyrite to metallic Fe with lime and charcoal gives very low yields. In the action of lime on pyrite, only a small amt. of FeO is formed, but considerable amts. of a difficultly reducible Ca-Fe oxysulfide are formed.

J. H. PERRY

Combustion of gas in the blast furnace. JOSEPH LILOT. *Rev. universelle mines* 9 [7], 188-90(1926).—The gas from a blast furnace varies among different furnaces, but is fairly const. for any given furnace. The gas studied had the % compn.: CO₂ 8.85, O 0.51, CO 26.32, H 2.00, CH₄ 1.00, N 61.32. Calcs. show that for a mixt. of this character, its combustion either with excess or with insufficient air results in less CO₂ in the gaseous products of combustion than does the theoretical amt. of air required, i. e., in the combustion of blast furnace gas the max. proportion of CO₂ in the gaseous product is obtained by theoretically correct combustion. For this reason an automatic CO₂ registering app. is effective in controlling the combustion of blast furnace gas, in which case the ideal CO₂ content of the gas is calcd. from the av. analysis of the latter. The supply of air is then varied to maintain the CO₂ const. C. C. DAVIS

A method of determining comparable blowing practices for iron blast furnaces. J. S. FULTON. *Proc. Eng. Soc. Western Penn.* 41, 480-75(1926).—A comparison of the blowing practice of individual stacks of the same plant and by comparative per-

formance of separate works. Factors affecting delivery in any blowing-engine running to give const. wind are listed. Gas analysis for various C rates, and cold blast for various C rates are shown in curves. For fair comparison of different furnace performances the data necessary are: (1) long tons of iron produced per day (av. of 30 days), (2) net lbs. of dry C in the coke per ton of iron, (3) cu. ft. of wind per min. at intake temp., humidity, barometric pressure, and blast pressure, and (4) min. actually on blast per day. From these there may be developed: (5) cu. ft. of air at 0° at 14.7 lbs., absolute pressure and humidity. 5 divided by 3 will show % of the wind accounted for or the plant volumetric efficiency; (7) adiabatic air and horse-power hrs. for compressing and delivering the wind specified in item (3) may be developed; (8) the adiabatic h p. hrs. may be apportioned per long ton of iron or short ton of C. A table shows the results from a no. of plants. Means of comparing operating results are shown. A discussion follows.

W. H. BOYNTON

Effect of the physical properties of ore and coke on the capacity of the blast furnace. T. L. JOSEPH, P. H. ROYSTER AND S. P. KINNEY. *Proc. Eng. Soc. Western Penn.* **41**, 428-59(1926).—An effort to show the relations existing between the physical properties of coke and ore and the furnace capacity, and to correlate with blast furnace practice some of the exptl. results of the work of the U. S. Bur. of Mines. Points considered include: combustion of coke in the furnace hearth, combustibility of coke, the effect of size, and coke in relation to furnace capacity. Also the effect of combustion zones on stock travel, the relation between size of ore and furnace capacity. No marked difference is evident in combustibility of cokes. The size of the coke has a greater effect on the length and shape of the combustion zone. The flow of stock in the shaft is not uniform and is regulated by C gasification in the localized zones of combustion at the noses of the tuyères. The capacity of the furnace may be increased by changes permitting better contact between gas and solid. A bibliography and an extended discussion are appended.

W. H. BOYNTON

Some observations regarding blast furnace design. A. G. MCKEE. *Proc. Eng. Soc. Western Penn.* **41**, 391-411(1926).—An address showing the trend of blast-furnace design toward a cylinder from top to bottom. Possible future developments of this trend are indicated. A proposed arrangement of large bell, cross-sections of blast-furnace construction, possible developments and a modern type of distributor are illustrated. A discussion follows.

W. H. BOYNTON

Modern blast furnace stoves. A. E. MACCOUN. *Proc. Eng. Soc. Western Penn.* **41**, 412-27(1926).—A brief study of blast furnace stoves. The 2-pass stove of either side- or central-combustion type is generally preferred, due to simplicity of construction and upkeep. Discussion brought out the advantageous practice of having 2 sets of app., and the necessity of studying the means of introducing gas to the stoves. A central stack for a group of stoves is advisable. Pressure burners tend to increase the gas-burning efficiency. The question of stove insulation is touched upon.

Reclamation of foundry sands. Method practiced at the Ohio Brass Co. A. A. GRUBB. *Metal Ind.* (N. Y.) **24**, 143-5(1926); cf. C. A. **20**, 354. An address.

E. J. C.

Melting high-chromium alloys in acid furnace. R. S. KERNS. *Foundry* **54**, 229-31; *Iron Trade Rev.* **78**, 812-4(1926).—Some of the uses of high-Cr alloy steels are given. Results indicate a very low Cr loss when melting these in the acid elec. furnace. About 30% of the charge of ferrochrome is melted with the scrap charge and the remainder is added in small quantities at short intervals. The pouring temp. is judged by means of the skin test when Ni is used and by the fracture when Ni is not used. The stream of metal entering the mold must not be stopped. The casting is ground carefully to guard against burning, which produces hard spots.

W. H. BOYNTON

Oven design shows advance. C. A. BARNETT. *Foundry* **54**, 240-1(1926).—A general classification of ovens includes: shelf-ovens, drawer-type ovens, portable rack-type ovens, car-type ovens, and conveyor ovens. Characteristics of each type are outlined. Economic, efficient operation of any type depends upon the kind of fuel, its cost, and the combustion and ventilating system efficiency. Coke, fuel oil, gas and electricity are employed, the latter being too expensive, in general, for core and mold ovens.

W. H. BOYNTON

Crystal growth in recrystallized cold-worked metals. W. FREITKNECHT. *J. Inst. of Metals* **1926** (advance copy), 35 pp.—This investigation was made to study the causes of the formation of the very large crystals obtained by Carpenter and Elam (C. A. **14**, 3391) on heating recrystd. Al sheets. The chief material used was pure commercial Al (99.6%) supplemented by some very pure Al (99.98%) and Ag. These were

subjected to various degrees of deformation followed by thermal treatment for varying lengths of time. Changes in crystal size were followed either by counting the crystals after each heat treatment or by photographs. From the results F. concludes that for Al: (1) The rate of crystal growth increases with severity of cold work and with increasing temp. Max. crystal size is obtained in sheets with 30% reduction in thickness. There are always some small grains left unabsorbed among the large crystals, and they can be embedded entirely in a large crystal. When growth is completed, min. grain size depends only on the temp. of heating. (2) Reduction of thickness is not an exact measure of the real degree of deformation; the degree of deformation is less in cross-rolled sheets than in sheets always rolled in the same direction, and is less in sheets rolled with many drafts than in sheets rolled with few. (3) Previous heat-treatment exerts considerable effect upon subsequent growth at another temp. When the temp. of the first treatment is the higher, subsequent growth is retarded; the reverse is true when the first treatment temp. is lower. (4) After recrystn. is completed all further changes are due to the growth of existing crystals. *No relation exists between crystal size and capacity to grow.* Small grains can invade larger ones. Growth is very discontinuous. Grains which have grown in an earlier stage can decrease, then remain stable, finally disappear or even start to grow again. (5) With very pure Al the crystal size is much larger after recrystn. is completed than in pure commercial Al; subsequent growth is faster; and the final grain size is a max. at 40% reduction in thickness. Twins occur more frequently in the very pure Al. Very pure Ag differs from Al only in that max. grain size results from 50% reduction in thickness and the final size is always much finer than in Al heated to a corresponding temp. Difference of internal energy due to differences in compn. or internal strain is the main cause of crystal growth. The two necessary conditions to give large crystals are (1) a not too great amount of remaining strain due to the mutual interference of the recrystd. grains, (2) a certain amt. of resistance which is slowly removed on heating for a long period. R. H. ABORN

The interpretation of the macrostructure of cast metals. R. GENDERS. *J. Inst. of Metals* 1926 (advance copy), 21 pp.; 14 photomicrographs.—This paper deals principally with the influence of factors necessary to correlate the interpretation of the macrostructure of non-ferrous alloys with that of steel. Crystn. of metal may occur in the metastable range of undercooling usually only by inoculation, while in a lower (labile) range spontaneous solidification may occur. Of the two types of crystals in metal macrostructure, the elongated type results from successive deposition of solid in the metastable cooling range, while the equi-axed polyhedral type may occur in either range. The macrostructure of ferrous alloys is briefly reviewed, the most desirable one consisting entirely of equi-axed (free) crystals, and therefore the lowest possible casting temp. is used. Indications gained from steel can be applied to cast non-ferrous alloys only to a limited extent because of the high thermal cond. of the latter (especially Cu alloys). This fast solidification tendency introduces another factor which is relatively negligible in ferrous alloys, *i. e.*, the flow of metal within the mold. To investigate these factors, G. prepd. ingots from 2 alloys, similar in f. p., density and thermal cond. but differing widely in color. A 90–10 red brass and a 50–30–20 (Cu, Zn, Ni) white nickel silver were used. They were poured one after the other into an exptl. cast-iron mold in 3 different proportions 25:75, 50:50, and 75:25. Variations in casting methods employed included top and bottom pouring, and single and multiple nozzle. The castings were sectioned, polished, etched and studied for color variations. Very slow and very rapid top pouring lead to predominant columnar crystn. the former by avoiding turbulence and the latter by allowing time for it to subside, thereby permitting simple temp. gradients. A medium pouring rate retards the growth of columnar crystals and encourages equi-axed crystal formation in the central region because turbulence of the liquid is concurrent with solidification. A multiple nozzle reduces turbulence, thus increasing the proportion of columnar crystals. Bottom casting tends to equalize the temp. and thus increases the proportion of equi-axed crystals. Columnar crystn. may lead to better physical properties than equi-axed crystn., since solidification is not directional in the latter, and there will be contraction cavities between crystal boundaries, which probably do not weld during working. Thus non-ferrous sand castings are in general weaker than chill castings. The greater the temp. interval between liquidus and solidus the greater the proportion of equi-axed to columnar crystals. This method has proved valuable in studying the mode of metal flow in molds of complicated design. R. H. A.

Recrystallization [of iron, steel, and copper] after hot deformation. H. HANEMANN and F. LUCKE. *Stahl u. Eisen* 47, 1117–22 (1925).—Cylinders of soft Fe (0.06% C, 0.02% Si, 0.14% Mn, 0.01% P and 0.027% S), steel (0.49% C, 0.67% Mn, 0.34% Si, 0.031% P and 0.029% C), and electrolytic Cu were heated to various temps. in a

vacuum furnace, then given a blow with a steam hammer to reduce their height, subsequently annealed at the same temp. for a short time, and slowly cooled. The grain size of the metal was then detd. by Jeffries' method. Soft Fe showed no recrystn. at 650° after this treatment, but at 750° recrystn. ensued with a min. reduction of 6.5% in height, the new grains being very coarse with 6.5–10% reduction, and fine again after more severe work; at 850° the min. reduction was 7%, but as the temp. was raised above this, recrystn. ensued after progressively less work. Similar results were obtained with steel and Cu, the min. temps. for recrystn. of which were 800° and 500°, resp., and the corresponding reductions in height 4.2 and 3.6%. In all cases the no. of recrystn. nuclei were proportional to the degree of reduction, a large reduction resulting in a finer grain.

B. C. A.

Certain new features in the microscopy of metals with high magnification. CARL BENEDICKS AND PER SEDERHOLM. *Jernkontorets Annaler* 109, 337–57 (1925).—The effect of vibration can be eliminated by loading the microscope, moving the center of gravity of the system to the part which is the most sensitive to vibrations, and by suspending the system elastically in a plane through or nearly through the center of gravity. Better images can be obtained by using oblique illumination, producing relief in the image. Some other features regarding the design of the app. are also discussed.

C. A. RUBAK

The polymorphism of iron. H. BREDEMEIER. *Z. anorg. allgem. Chem.* 151, 109–12 (1926).—A short thermodynamic consideration of α -, β - and γ -Fe.

J. H. PERRY

The thermoelectricity of steels in relation to working and tempering. PAOLO ROSSI. *Nuovo cimento* [N. S.] 2, 399–414 (1925).—Thermocouples were made of worked steel vs. annealed steel and of tempered steel vs. annealed steel. The e. m. f. of these couples were measured at diff. temps. With increase in temp there is a slow increase in e. m. f. followed by a diminution to zero at the critical point of steel. The inversion in thermoelec. effect in the tempered steel-annealed steel couples indicates an inversion in sign of the 2 consts. a and b in Avenarius' formula. The behavior of tempered steel on heating is similar to that of cold-worked steel in that the e. m. f. falls to zero after reaching a max.

L. T. FAIRHALL

[Hardness of] chill-cast iron. P. GOERENS AND H. JUNGBLUTH. *Stahl u. Eisen* 45, 1110–7 (1925).—The Shore hardness no. of chill-cast Fe increases in direct proportion to the C content from 56 at 2.4% C to 84 at 4.2% C when the Si content is const. The thickness of the hard outer layer varies considerably with the rate of cooling, cooling temp., and Si content. In general, the thicker the walls of the mold, i. e., the greater the cooling on pouring, the thicker is the hard layer, and the larger the Si content the thinner the hard layer. With 0.3% Si the thickness is 60 mm. with 0.8% Si, 15 mm., and with 1.1–1.4% Si, 0.8–0.6 mm. Mn between 0.25 and 0.6% and S between 0.17 and 0.068% have no influence on the hardness.

B. C. A.

Alloys of iron and iron sulfide. B. BOGITCH. *Compt. rend.* 182, 217–9 (1926).—Fe-FeS mixts. did not form 2 liquid phases when melted out of contact with foreign bodies (in a refractory crucible under a layer of molten Na silicate); when melted in a graphite crucible, under molten Na silicate, at about 1600°, there was sepn. into 2 liquid phases, visible with the naked eye or under a low magnification, the upper one with about 22% (21.7–23.1%) S, and the lower one with 4.2–7.9% S and 2.4–1.3% C. At 1350–1400° no sepn. took place, even after heating 1 hr. The relative thickness of the layers varies with the S content, the thickness of the top layer decreasing with the S content. Fusion under oxidizing conditions caused no sepn. into layers, but considerable segregation of the S (extreme values found being 21.10% S in the bottom and 10.3% in the center). Addn. of low percentages of Cu causes considerable segregation; with more than 3% Cu there is formation of 2 layers, the upper one being a Cu mat. A. P.-C.

Properties of certain heat-treated nickel-chromium steels. LEON GUILLET. *Compt. rend.* 182, 249–51 (1926).—Test bars of steel contg. C 0.26, Ni 3.76, Cr 0.67, Mn 0.54, Si 0.11, S 0.037, P 0.0 and 21% were subjected to the following treatments: (A) heated 20 min. in a salt bath at 900°, quenched in oil, tempered at 650°, cooled between 650° and 410° in 35 hrs., air cooled from 410° to atm. temp., tempered a 2nd time at 650°; (B) same as A, except that the order of the 2 temperings was reversed. After A, the test bars had a resiliency of 16.4 and bending angle of 163°, while after B the values were 5.6° and 166°, resp. Comparative resiliency tests, carried out on bars treated according to B, were made at temps. of 200–650° and at atm. temp. after heating to the same temps. and air-cooling. The results show that the brittleness has been destroyed in the tests made at 200° and over, while normal resiliency is restored in the bars tested at room temp. after having been heated to about 500° or over. After heating to 500–550°

and air cooling the metal is not brittle, unless cooling was very slow. The resistance to repeated impacts of the steel with low resiliency is much lower than that of the other one, but the tensile strengths of the two were practically identical. Micrographic examn. and dilatometric and thermo-elec. measurements showed no difference between the bars treated according to A and B.

Hard spots on steel forgings. J. D. GAT. *Blast Furnace & Steel Plant* **14**, 74-8 (1926).—A summary. Some generalizations, some facts as a basis for further investigations and some means of elimination and prevention of hard spots are mentioned. Hard spots are experimentally traced to C deposits from fuel oil. Several photomicrographs of cast iron, steel and a considerable range of annealing temps. are shown.

Effect of temperature and chemical composition on the viscosity of iron. P. OBERHOFFER AND A. WIMMER. *Stahl u. Eisen* **45**, 969-79(1925).—The viscosity is measured by the logarithmic decrement of a pendulum swinging in the molten Fe. For pure Fe-C alloys a sudden increase in viscosity is observed at 1335° for 2.62% C, and 1180° for 3.43% C, which corresponds with the sepn. of solid solns. from the liquid. P increases the viscosity of the Fe, but lowers the initial solidifying point, which accounts for the apparent increase in fluidity in practice. MnS increases the viscosity considerably, and C and Si also increase it. These observations are confirmed by expts. with various kinds of pig Fe.

Phosphide in manganese steel. I. PIWOWARSKY. *Stahl u. Eisen* **45**, 1075-6 (1925).—Photomicrographs of cast Mn steel contg. 1.39% C, 14.2% Mn, and 0.13% P, and possessing unsatisfactory toughness, showed that a phosphide eutectic was present in the grain boundaries in addn. to the carbide network. Matwieff's etching process with alk. and neutral solns. of Na picrate served to indicate the presence of free phosphide and free carbide in the boundary inclusions. On heating for 15 hrs. *in vacuo* at 1050° and quenching in cold water the carbides and phosphides were dissolved. The phosphide eutectic is deposited in heterogeneous components in consequence of the incomplete diffusion of the primary mixed crystals. The carbides and phosphides are not in intimate mixt. but sep. The quenched steel contains micro-cavities in the austenite grains, but specimens which showed no phosphide segregation did not show such cavities after quenching. It is suggested that the soln. of the phosphide eutectic increases the contraction of the Fe.

Behavior of iron, brass, and bronze in saline waters at the ordinary temperature and at the temperature and pressure of a boiler. O. BAUER. *Stahl u. Eisen* **45**, 1101-9 (1925).—See C. A. 20, 1211.

The three-component system: iron-chromium-carbon. TH. MEIERLING AND W. DENECKE. *Z. anorg. allgem. Chem.* **151**, 113-20(1926).—A study of the Fe-Cr-C system, with concns. of C varying from 0.70 to 2.60% and of Cr from 0 to 20%, has confirmed the hypotheses of Fischbeck (C. A. 19, 1084). A study of the change in the Brinell hardness has yielded the following data on Brinell hardness for (a) normal and (b) very slow annealing, resp., the % of C and of Cr varying as shown: 0.74% C, 1.99% Cr, 255, —; 0.75% C, 4.96% Cr, 500, 230; 0.73% C, 8.92% Cr, 675, —; 0.76% C, 14.99% Cr, 480, 250; 0.77% C, 19.70% Cr, 410, 200. The soly. limits of the mixed crystal in the Fe corner of the 3-component diagram, as well as the location of the perlite point with different concns. of Cr, have been detd.

"Wiegold" [dental] alloy. W. ZIMM. *Deut. Zahnärztl. Wochschr.* **28**, 1-4(1925).—"Wiegold" alloy is a brass contg. Al and resembling Au in appearance. The old alloy contained 66.93% Cu, 32.79% Zn, 0.28% Al, and traces of Pb and Fe, while the latest alloy contains 67.73% Cu, 32.0% Zn and 0.27% Al. The structure of each alloy is homogeneous α , and this structure is maintained after annealing and slow cooling. "Randolf metal," on the other hand, loses its homogeneity even after a short anneal at a low temp. Neither alloy is quite homogeneous after normal cooling of a cast ingot in air, but the second becomes more so on aging. The best results are obtained by casting in a hot mold, followed by very slow cooling. Correctly worked "Wiegold" has a relatively high resistance to corrosion, and in this respect represents a considerable advance on "Chrysite" and "Randolf metal."

"Wiegold" dental alloy. E. WANNENMACHER. *Deut. Zahnärztl. Wochschr.* **28**, 54(1925).—A reply to Zimm (cf. preceding abstr.). The "Wiegold" alloy analyzed by W. contained 68.1% Cu, 31.3% Zn, 0.5% Pb and no Al; it was not metallographically homogeneous and was less resistant to corrosion than "Randolf metal." W. considers that brass alloys should not be used for dental purposes.

"Wiegold" [dental] alloy. J. BOCK. *Deut. Zahnärztl. Wochschr.* **28**, 68(1925).—B. finds 0.35% Pb in "Wiegold," approx. the same Pb content in "Randolf" and

"Goldal," and 1.39% Pb in "Chrysite," and agrees therefore with Wannenmacher's criticism of Zimm's paper (cf. preceding abstr.). B. C. A.

Alloys of high electrical resistance. S. F. ZHEMCHUZHNIK, S. A. POGODIN AND V. A. FINKELZEN. *Russ. Acad. Sci.* 1923, 3-47.—Mainly a summary of work dealing with Cu-Ni, Mn-Cu, Mn-Ni Cr-Ni and Fe-Ni alloys B. C. A.

Improving aluminum-lithium alloys. P. ASSMANN. *Z. Metallkunde* 18, 51-4 (1926).—Alloys contg. up to 12% Li were carefully prepd. and the corresponding portion of the equil. diagram was detd. by thermal and microscopic methods. The amt. of Li held in the α -solid soln. was found to decrease from a max. of 3.5% at 598° to 2.2% at room temp. A eutectic between the α - and β -phases was found to melt at 598° and contained 7.8% Li. Alloys with more than 4% Li were found to be strongly corrodible, and the oxidizing tendency of the alloys contg. more than 10% Li was sufficient to decompose water; because of this difficulty no alloys were made contg. more than 12% Li. The equil. diagram of Czochralski and Rassow (Czochralski, *Moderne Metallkunde*, page 36) was essentially confirmed. Brinell tests of annealed specimens showed rapid increase in hardness between 2 and 3.5% Li (the satn. range of the α -solid soln.), with a slower increase above 3.5%. Replacing the Li by Mg gave a similar curve lying below the former on a wt. % basis, but above on a % basis. Possible improvement by mech. and thermal treatment was investigated. A max. increase of 16% in hardness (65-76) in the α -satn. limit region was obtained by annealing cold-worked material at 500°, quenching and aging 5 days at room temp. Aging at 100° gave no noticeable difference, while at 200° the beneficial effect was entirely lost. Prolonging the annealing time (previous to quenching) from 1/2 hr. to 6 hrs. resulted in a higher Brinell value for the cast than for the worked material. The effect of Cu or Zn in Al-Li alloys also was investigated. Max. hardness (> 80) was obtained in a 0.4% Li alloy contg. either 4% Cu or 12% Zn quenched from 500° and aged at room temp. The detrimental effect of higher aging temps. was observed also in these alloys. Hardness comparable with that of duralumin can be obtained by the addition of Mn and Ni. The cause of this increased hardness was in no case evident under the microscope. Further investigations bearing on the theory of these effects will follow in a later paper. Cf. C. A. 20, 1381. R. H. ABORN

Notes on galvanizing. ANON. *Chemistry and Industry* 45, 139 (1926) —Zn coatings on impure Fe are not lasting, as the impurities (Cu, C, Si) set up local electrolytic action. T. S. CARSWELL

The chemical reaction of the rusting of iron. JOEL SCHEIBER. *Farbe u. Lack* 31, No. 11, 125 (1926).—A review of the electrochem. theory of rusting. R. J. M.

Why boiler tubes burnt out. G. C. REINHARD. *Power* 63, 513 (1926) —Corrosion of tubes in an oil-fired boiler appeared to be related to the formation of ferrous and ferric sulfates on the tubes. The fused sulfates acted as a flux for the Fe, weakening the tube enough to cause blistering and blowouts. The cleaner the tubes were, the more rapidly did corrosion occur. D. B. DILL

Peculiar examples of corrosion of boiler parts. ROBERT STUMPER. *Feuerungs-technik* 14, 97-8 (1926).—A piece of open-hearth steel in contact with Cr-Ni steel lost about twice as much by corrosion as an isolated piece in the same water. Anodic corrosion of a bronze contg. 2.4% Zn occurred in a boiler water having 0.5 g. Na₂CO₃ per l. ERNEST W. THIELE

Cutting tests with high-speed steel. R. HOHAGE AND A. GRUTZNER. *Stahl u. Eisen* 45, 1126-30 (1925).—The cutting power of a high-speed steel contg. normal amounts of C and Cr increases rapidly with the W content between 17 and 22% W, but is practically const. with 23-27% W; addn. of V to steel contg. 14-18% W increases the cutting power, but V. has no effect when the W is above 22%. The curve showing the relation between the W and V contents for max. cutting power is a straight line. Mo increases the cutting power more than W, 0.6 pt. Mo having the same effect as 1 pt. W, but the Mo steels have a coarser grain structure when annealed above 1100° for hardening. B. C. A.

Welding aluminum. E. LÜDER. *Apparatebau* 38, 57-8 (1926) —A general discussion. J. H. MOORE

Autogenous and electrically welded boilers and tanks (holders). E. HÖHN. *Z. Ver. deut. Ing.* 70, 117-22 (1926).—A comprehensive report on tests conducted for an association of steam boiler owners in Switzerland, covering welding by water gas, oxy-acetylene and elec. arc; comparisons with riveted joints and seams, etc. Illustrated by numerous detailed drawings, tables and graphs. W. C. EBAUGH

The industrial application of detonating gas and other innovations in the metal-atomizing process. M. U. SCHOOP. *Z. angew. Chem.* 39, 146-7 (1926).—New forms of

burners are described wherein a mixt. of gas and O is effected at some distance from the burner, and then mixed with more O at the burner through the use of two slit openings facing each other. Increased metal deposition and decreased gas consumption per unit of time are claimed. Particles of metal are said to be shot off larger and hotter than were obtained with the earlier types of "pistols," and produce better coatings.
W. C. EBAUGH

Roasting and burning ores, etc. (APOLD, FLEISSNER) 13. Corrosion and rusting of wrought iron and steel gas barrel (ANON.) 21. Crude coal gas for recovering scrap Cu and brass (BERTHOLET) 21. Selecting refractories for use in metallurgical furnaces (THEWS) 19. Gas producer [adapted for iron smelting] (Brit. pat. 237,883) 21.

Ore flotation separation. C. P. LEWIS. U. S. 1,577,328, March 16. An ore pulp, *e. g.*, one contg. Pb, Zn and Fe, is mixed with a flotation agent comprising a heavy hydrocarbon and a hydrocarbon of the benzene series, *e. g.*, a mixt. such as "solvent naphtha, and subjected to froth flotation. Cf. C. A. 20, 33.

Mineral flotation separation. B. M. McATEE. U. S. 1,579,722, April 6. Mech. features.

Multiple-deck thickener for ore pulps, etc. C. W. ANKENY. U. S. 1,578,625, March 30.

Metallic values from concentrates or slimes. H. FLECK and W. G. HALDANE. U. S. 1,577,217, March 16. Concentrates or slimes which may contain metallic values such as Ra compds. are treated with NH_4HF_2 or other reagent capable of converting the contained Si into a volatilizable compd., which is allowed to evap. from the mass unaccompanied by any of the values to be recovered.

Cement and metallic iron from ores. E. C. ECKEL. Brit. 237,779, Nov. 17, 1924. A mixt. of Fe ore low in SiO_2 , aluminous material such as bauxite, and CaCO_3 is fused, reduced Fe and slag are allowed to sep. and the slag is ground to form cement. Various details are given. Cf. C. A. 19, 2631.

Recovery of flaky precious metals from sand. D. H. DONEGAN. U. S. 1,576,954, March 16. Mech. features.

Blister copper from "black copper." M. H. MERRISS. U. S. 1,576,776, March 16. A mass of "black copper" or similar material is preliminarily heated until it is at least partially melted. Air is then blown through it and the quantity and temp. of the air are controlled to effect rapid oxidation of impurities. The heat produced by the oxidation is utilized for producing blister Cu from the mass.

Treating copper ores. W. E. GREENAWALT. U. S. 1,579,356, April 6. Cu ore is agitated with an acid soln. to ext. a portion of the Cu, the soln. is sepd. from the ore and the ore sands are sepd. from the ore slimes. Cu is pptd. from the soln. and the sands are treated by percolation with the barren soln. from which the Cu has been pptd. Cf. C. A. 19, 2321.

Treating ores containing copper, gold and silver. H. V. WELCH. U. S. 1,578,618, March 30. Au, Ag and Cu are extd. from ore by a cyanide soln. and the soln. is treated with a reagent such as Zn to ppt. the Au, Ag and Cu and regenerate sol. cyanide for further use in ore treatment. The cyanide content of the soln. is so adjusted that the soln. during the pptn. of the Cu contains an excess of 4 mols. of cyanide (calcd. as NaCN) for each mol. of Cu in the soln.

Refining copper-nickel mat. N. V. HYBINETTE. U. S. 1,577,422, March 16. In utilizing bessemerized Cu-Ni mat Cu is cemented on it from a Cu-Ni sulfate soln., the remaining mat and cement Cu are roasted, leached with H_2SO_4 to form a CuSO_4 soln., the leached residue is reduced, dissolved to form a Cu-Ni soln. and Cu from this soln. is cemented on a further quantity of bessemerized mat.

Separating zinc or other metals from ores, etc. L. E. WEMPLE. U. S. 1,578,694, March 30. Metalliferous material contg. a volatilizable metal such as Zn ore is mixed

with carbonaceous fuel and flux and the mixt. is blasted into a heated furnace chamber in which the temp. is maintained high enough to effect reduction and volatilization of the metal. The vaporized and fumed material is passed through a tortuous passage, while hot and under oxidizing conditions for part of the time at least, and the oxidized product is collected free from slag.

Metallurgical furnace adapted for zinc production. P. THARALDSEN. U. S. 1,579,340, April 6.

Cast-iron car wheels. J. M. KELLER. U. S. 1,579,214, April 6. Chilled tread portions of cast Fe car wheels comprise 3-4% of combined C and 0.6-3.5% Cu.

Purifying molten metals. H. G. LAPSLEY. U. S. 1,578,014, March 23. Molten metals such as Cu, Fe or steel are treated with a chem. compd. of Al and B.

Gas-fired furnace for melting metals, etc. W. H. CHENOWETH and G. C. SCHUMPE. U. S. 1,579,077, March 30.

Temperature and combustion regulation in melting iron or other metals. Y. A. DYER. U. S. 1,578,648, March 30.

Refining crude iron. F. BURGERS. U. S. 1,578,009, March 23. Fuel is introduced into a furnace through a chute and preheated by gases arising from burning fuel. Crude Fe is melted in a sep. furnace and the molten metal is conveyed to the refining furnace and introduced at a point near its vertical axis and below the upper limit of incandescence.

Aluminum alloy. V. E. HYBINETTE. U. S. 1,579,481, April 6. Light alloys are described which contain Al in excess of 90% together with Ni 0.5-3.0 and metals of the Cr group 0.25-1.50%, and which also may contain other ingredients.

Aluminum alloy. T. S. FULLER and D. BASCH. U. S. 1,578,979, March 30. An alloy which is suitable for casting comprises Al together with Zn 3-8 and Mg 0.25-1.5%.

White gold alloy. E. M. WISE. U. S. 1,577,995, March 23. An alloy contg. 30-80% Au contains also Ni, Cu and Zn in the relative proportions of Ni 33-53.1, Cu 26.4-46.5 and Zn 10.6-30.7 parts.

Plated wire. C. G. KING. U. S. 1,579,819, April 6. A seamless wire adapted for the manuf. of jewelry comprises a core of Ag and a shell of "white gold" of approx. the same color as the core.

Chill molds for casting ingots or plates for use in rolling mills. O. JUNKER. Brit. 237,622, July 26, 1924. H₂O-cooled mold sides are formed of thin sheet metal, preferably Cu.

Electric system for protecting boilers, evaporators or other metallic structures against corrosion. G. H. ELMORE and H. J. CREIGHTON. U. S. 1,576,581, March 16.

Protecting ferrous metals from corrosion. I. T. BENNETT. U. S. 1,578,254, March 30. Steel or similar metal is coated with Cr and with an overlying layer of Ni.

Cutting or welding metals by flame. R. H. BROWNLEE and R. H. UHLINGER. U. S. 1,577,171, March 16. A flame for cutting or welding is formed with O and a gas mixt. comprising H with a smaller proportion of natural gas or other hydrocarbon material. CO 10% or less may also be present.

Electrode for arc welding. E. A. E. TÖRNBLÖM. U. S. 1,577,506, March 23. Metal electrodes are coated with an alk. compn. such as K₂CO₃ mixed with gum tragacanth.

Electrodes for resistance welding. BRITISH THOMSON-HOUSTON CO., LTD. Brit. 237,902, July 30, 1924. A mixt. of finely divided W 9 and Cu 1 part is molded under pressure and heated to 1200-1600° in H.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Organic chemistry and X-rays. SUZANNE VEIL. *Rev. gen. sci.* 36, 535-41 (1925) — A popular review. DONALD W. MACARDLE

Chlorine in the organic chemical industry. J. T. CONROY. *Trans. Am. Electrochem. Soc.* 49 (preprint) (1926).—A non-technical discussion of the uses and applications of Cl in the prepn. of org. compds. Achievements are noted and new lines of investigation forecast. C. J. BROCKMAN

The hydrogenation of organic substances at a high temperature and under pressure. ANDRÉ KLING AND DANIEL FLORENTIN. *Compt. rend.* 182, 389-91 (1926).—An attempt is made to explain the mechanism of the Bergius process of hydrogenating org. substances under pressure at elevated temps. There exists for each mol. c. temp. above which dissociation or a breaking down (cracking) of the mol. begins. This temp. corresponds

in most instances to the thermic level at which hydrogenation of the new simpler mols. is possible. Insofar then as hydrogenation under pressure and at an elevated temp. is concerned, it is probable that mol. H reacts on the nascent org. mols. at the instant when the original mol. dissociates. This method should be of value in the general study of the *influence of heat on org. compds.*, for with H present to combine immediately with new mols. there is no tar formed and if conditions are suitably chosen, only satd. hydrocarbons are formed. The method also allows mols. of differing stability to be distinguished and indicates which of any no. of constitutions attributed to them is the most probable. Thus oils which can be hydrogenated only with great difficulty give almost exclusively cyclic (C_6H_6) mols., indicating that the original mols. have a cyclic structure. It can be shown in this way that oils from French schists contain besides aliphatic and naphthene compds. about 10% of derivs. with a C_6H_6 nucleus which are hydrogenated only in a 2nd phase of the process.

C. C. DAVIS

Liberation of hydrogen from carbon compounds. II. The interaction of ethyl alcohol, acetaldehyde and acetone with fused caustic alkalis. H. S. FAY AND E. L. SCHULZE. *J. Am. Chem. Soc.* **48**, 958-68(1926); cf. *C. A.* **18**, 3357.—The reactions taking place when the vapors of EtOH, AcH and Me_2CO are bubbled through an excess of an equimol. mixt. of fused caustic alkalis may be readily explained in terms of an apparently general type reaction $(M = Na \text{ or } K), R(H)_n + n MOH \rightarrow R(OM)_n + nH_2$, which involves the acidic dissociation of the alkalis, the ultimate oxidation of the C compd. to carbonate and the liberation of H. Similar type reactions explain the intermediate formation of acetates and CH_4 . The incomplete reaction of EtOH at temps. of 250° and 300° and the occurrence of several simultaneous changes made it impossible to establish exact stoichiometrical ratios but the data obtained confirmed in some measure the occurrence of the following reactions: $EtOH + NaOH \rightarrow AcONa + 2H_2$; $AcONa + NaOH \rightarrow Na_2CO_3 + CH_4$; $EtOH + 6NaOH \rightarrow Na_2CO_3 + Na_4CO_4 + 6H_2$; $EtOH \rightarrow C_2H_4 + H_2O$. AcH reacted completely with the fused alkalis at 250° according to the equation $AcH + NaOH \rightarrow AcONa + H_2$. At 300° and 350° the yields of H, CH_4 and carbonates were practically those calcd. for the reaction $AcH + 2NaOH \rightarrow H_2 + CH_4 + Na_2CO_3$. The reactions of Me_2CO were analogous to those of AcH. At 250° CH_4 and acetates were the chief products of the reaction which conformed, at least to the extent of 70% of the calcd. amts., to the reaction $Me_2CO + NaOH \rightarrow AcONa + CH_4$. At 350° the yields of CH_4 and carbonates were more than 90% of those calcd. from the equation: $Me_2CO + 2NaOH \rightarrow Na_2CO_3 + 2CH_4$. Details of runs are given.

C. J. WEST

Action of nitric-sulfuric acid on dichloro- and monochloromethyl ether. J. HOUBEN AND E. PFANKUCH. *Ber.* **59B**, 86-9(1926).—Moreschi (*C. A.* **13**, 3319) assigned to the compd. he obtained from $(ClCH_2)_2O$ with $HNO_3-H_2SO_4$ the structure $O-NCH_2OCH_2ONO_2$ (I) because, according to him, $MeNO_2$ is produced from it on hydrolysis. As a matter of fact, H. and P. find that on alk. hydrolysis it loses 0.5 of its N as nitrite and the other 0.5 as nitrate, but that I is nevertheless correct is shown by the mol. refraction. Together with I is formed a 2nd compd. (II) of considerably higher b. p., usually only in small amt. but sometimes becoming the chief product: the condition under which this occurs have not been definitely established. II seems to be a *nitro-nitroxymethylal*, $O_2NCH_2OCH_2OCH_2ONO_2$. $ClCH_2OMe$ reacts in the same way as $(ClCH_2)_2O$ with $HNO_3-H_2SO_4$. I b_p: 48°, mol. wt. in C_6H_6 147.9, d₄ 1.5005, n_D 1.43276, yield, generally about 60%. II b_p 88-9° (the distn. must be carried out with the greatest care and with only small amts. of material, as the II explodes with extreme violence), mol. wt. in C_6H_6 183-93.

C. A. R.

Organic compounds of phosphoric acid. I. Formation of primary phosphoric acid esters. F. ZETTSCHKE AND M. NACHMANN. *Helvetica Chim. Acta* **8**, 943-5(1925). The method depends on the reaction of AgH_2PO_4 in excess H_3PO_4 with the halide of 1 mol. halogen is quant. pptd., even when dihalides are used, but the yields are small, owing possibly to sapon. of the esters by the excess H_3PO_4 . 7.7 g. Ag_3PO_4 in 12 cc. 84% H_3PO_4 at 60-70°, treated with 8 cc. H_2O , cooled with ice, and shaken with 6.3 g. $PhCH_2Cl$ in 20 cc. alc., added in small portions, then shaken 1 hr. longer, gave, when extd. with Et_2O , treated with $Ba(OH)_2$, and shaken out again with Et_2O to remove a pleasant smelling by-product, 13.7% of $PhCH_2OPO_3Ba$. C_2H_5I yielded, in the aq. portion after the 1st Et_2O extn. 10% of $C_2H_5OPO_3Ba$. $HOCH(CH_2I)_2$ yielded, also in the aq. fraction, after successive treatment with H_2S , $Ba(OH)_2$, and CO_2 , the *Ba 1-iodo-2,3-propanediol-3-phosphate*, slightly brownish, friable, hygroscopic mass. $(CH_2)_3Br_2$ gave *Ba 1-bromopropanol-phosphate*, similar to the preceding salt. No ester salts could be isolated when $o-O_2NC_6H_4CH_2Cl$ and $ICH_2CH(OH)CH_2OH$ were used.

M. HEIDELBERGER

Complex salts of β, β', β'' -triaminotriethylamine with nickel and palladium. F. G. MANN AND WM. J. POPE. *J. Chem. Soc.* 1926, 482-9; cf. C. A. 20, 578.—($\text{H}_2\text{NCH}_2\text{CH}_2$)₃N.3HCl and 33% aq. NaOH are warmed until NaCl alone remains undissolved; the mixt. is then poured into a hot soln. of Ni succinimide in EtOH, the green soln. boiled 30 min. (blue), cooled, filtered and concd. when the deep blue soln. contains 2 complex ions $[\text{Ni tren}]^{++}$ and $[\text{Ni}_2 \text{tren}_2]^{++}$ [$\text{tren} = (\text{H}_2\text{NCH}_2\text{CH}_2)_3\text{N}$]. Pouring the soln. into a hot concd. soln. of KSCN gives *triaminotriethylaminenickelous thiocyanate* (I), deep blue bipyramidal orthorhombic crystals, darkens 260°, m. 285° (decompn.); with Na_2PtCl_6 there ppts. the *nickelous platinum tetrachloride dithiocyanate*, russet-brown, shrinks 211-3°, does not m. 280°. I and Ag_2SO_4 give the *nickelous sulfate heptahydrate*, deep blue; over CaCl_2 for 24 hrs. there results the *dihydrate*, reddish blue powder, which on prolonged exposure to CaCl_2 or on heating to 100° *in vacuo* gives the *anhyd. sulfate*, pale blue, does not m. 300°. Mol. wt. detns. in H_2O indicate that the sulfate has the simple formula $(\text{Ni tren})\text{SO}_4$ and that the apparent mol. wt. approaches to 150 at great diln. and increases with increasing concn. as the degree of ionization falls. The equiv. cond. at 25° is also given. Pouring the above concd. soln. into KI soln. gives the *tristriaminotriethylaminenickelous tetraiodide* (II) deep violet with 3.5H₂O; a dihydrate was obtained in 1 expt.; the anhyd. salt, pale violet, m. 307-9 (decompn.); *tetrabromide*, pale reddish blue, does not m. at 290°. Attempts to resolve the iodide were unsuccessful; the *tetra-d- α -bromocamphor- π -sulfonate*, pale violet, shrinks 180°, m. 183-5° (decompn.), was converted into the *tetrapurate*, dark yellow, with 3H₂O, m. 205-6° (decompn.) and inactive. The *tetra-d-camphor β -sulfonate*, reddish violet, m. 233-5°, likewise gave an inactive iodide. II and $\text{NH}_4\text{d-bromocamphorsulfonate}$ in H_2O gave *triaminotriethylaminenickelous d-bromocamphorsulfonate*, bluish violet plates with 2H₂O, changed to the anhyd. blue salt at 110°, m. 263-6° (decompn.); with KSCN it gives I. This degradation of the Ni complex of coordination no. 6 to that of 4 by NH_4 salts was found to be general. *Triamino triethylaminepalladium iodide*, cream-colored powder, darkens 220°, m. 221-6° (decompn.); if the soln. before pouring into KI, as above, is made acid and treated with PdCl_2 soln., a chocolate-colored ppt. is formed, which may be the palladium chloride ($\text{Pd tren})\text{PdCl}_2 \cdot \text{H}_2\text{O}$; it decomps. on crystn. from boiling H_2O . C. J. WEST

$\gamma, \gamma', \gamma''$ -Triaminotripropylamine and its complex compounds with nickel. F. G. MANN AND WM. J. POPE. *J. Chem. Soc.* 1926, 489-93.—Passing dry NH_3 through molten phthal- γ -bromopropylimide at 150° gives the *HBr salt*, m. 213-5° (crystg. from AcOH with 1 mol. of AcOH of crystn. lost at 100-5°), of *triphtalimidetripropylamine*, m. 150-1°; heating with 1.1 HCl for 7 hrs. gives $\gamma, \gamma', \gamma''$ -triaminotripropylamine-4 *HCl* (I), slightly deliquescent, crystg. with 0.5H₂O not lost *in vacuo* at 100°, m. 227-9° (decompn.); *chloroplatinate*, orange needles with 3H₂O, darkens 250°, m. 257-8°, *chloroaurate*, orange-yellow, m. 191-2° (decompn.), contains 3H₂O; *picrate*, pale yellow, softens 190°, m. 222° (decompn.); 1 g. dissolves in about 1 l. of H_2O . *Tri Bz deriv.*, m. 129-31°. I, warmed with 33% aq. NaOH, the soln. added to a hot soln. of Ni succinimide in EtOH, boiled, filtered and concd., then filtered into a concd. cold soln. of KSCN, gives *triaminotripropylaminenickelous thiocyanate*, $\text{C}_{11}\text{H}_{24}\text{N}_6\text{S}_2\text{Ni}$, pale lilac-blue, m. 260-1° (decompn.); on recrystn. from hot H_2O some decompn. occurs, the iodide, with 1.5H₂O, apple-green powder, if the concd. soln. is poured into concd. hot KI soln. (instead of the KSCN soln.), there results the *hydroxyiodide*, deep blue, with 2H₂O; while it is stable in the presence of hot H_2O , it cannot be heated at 100° *in vacuo* without slight decompn.; with KI there results a sea-green addn. product, which is decompd. by cold H_2O . Aq. solns. absorb CO_2 from the air. C. J. WEST

Anomalous course of Grignard reactions. G. STADNIKOV AND ANNA WEIZMANN. *J. prakt. Chem.* 112, 177-86 (1926).— PrMgBr and other Grignard reagents from alkyl halides react normally with BzH , forming sec. alcs.; the same Mg-org. compd. in the form of a complex with PhNMe_2 or with benzohydryl Bu ether reacts with BzH but gives little or no sec. alc., the starting materials being recovered. Several expts. are quoted. C. J. WEST

Organic lead compounds. RICHARD DANZER. *Monatsh.* 46, 241-4 (1926). *Tetrabutyllead*, b_{10} 156° (in CO_2 stream), in 7 g. yield from 32 g. PbCl_2 and BuMgCl from 20 g. BuCl ; mol. wt. in freezing C_6H_6 normal. *Dibutyllead dibromide*, pale yellow needles, results as a by-product. *Triisobutylbutyllead*, b_{10} 145-6°, from BuMgCl and (isoBu)₃PbBr. C. J. WEST

Distillation of aqueous formaldehyde solutions. E. W. BLAIR AND H. TAYLOR. *Soc. Chem. Ind.* 45, 65-6T (1926); cf. C. A. 19, 1214.—Distns. of aq. CH_2O solns. at concns. from 1 to 45% indicated that a mixt. of const. b. p. is formed, contg. about 30% CH_2O . T. S. CARSWELL

Preparation and use of aldehyde esters formed by ozonation of the methyl esters of various unsaturated acids. C. R. NOLLER AND ROGER ADAMS. *J. Am. Chem. Soc.* **48**, 1074-80 (1926).—A mixt. of air and O_3 was bubbled through a soln. of 0.5 mol. of unsatd. ester in 300 cc. glacial AcOH until Br-AcOH was no longer decolorized. The ozonide was dild. with Et_2O , and Zn dust and H_2O added to decomp. the ozonide and to prevent oxidation of the aldehydes formed. The yield averages 55-60%. Me oleate gives Me η -aldehydoctanoate (I), b_3 111-2° (cor.), n_D^{20} 1.4384, d_4^{20} 0.9704; semicarbazone, m. 104-5°. Me undecylenate gives Me θ -aldehydononanoate, b_3 120-1° (cor.), n_D^{20} 1.4410, d_4^{20} 0.9663; semicarbazone, m. 98-100°. Me erucate gives Me λ -aldehydodecanoate, b_3 152-3°, n_D^{20} 1.4469, d_4^{20} 0.9399; semicarbazone, m. 116.5-7.5°. On standing I gives a trimer, m. 34-6°, mol. wt. in freezing C_6H_6 506, 526; it appears to be depolymerized by heating at 3 mm. and 200°. The trimer of the free acid m. 112-3°. On standing in the air these esters oxidize readily to the esters of the corresponding acids; these esters could also be isolated from the high boiling fractions. The Me (mono) ester of azelaic acid, m. 22-4°, b_3 158.5-9.5°, n_D^{25} 1.4451, d_4^{25} 1.0348; of sebacic acid, m. 40-1°; of brassylic acid, m. 57-7.5°. I and BuMgBr give 38% of Me θ -hydroxytridecanoate, b_3 154-5°, n_D^{20} 1.4490, d_4^{20} 0.9316. The free acid m. 49-51°. From the ester through the bromide and the unsatd. acid there is formed $C_{13}H_{26}O_2$, m. 42-2.5° (cor.). C. J. WEST

Preparation of dibromoacetaldehyde acetal by direct bromination of paraldehyde. RUDOLF DWORZAK. *Monatsh* **46**, 253-9 (1926).—The action of 1 mol. Br upon 1 mol paraldehyde gives a small amt. of dibromoacetal, in some cases in sufficient amt. to be isolated. Two mols Br give about 40% of the acetal, but also considerable amts. of tetrabromobutyraldehyde. Three mols of Br also give, in the 1st instance, the same products; some tribromoacetal is also formed, but the amt. is not sufficient to make the method 1 of prepn. C. J. WEST

Effect of heat on chloral hydrate. J. D. MOUNFIELD AND J. K. WOOD. *J. Chem. Soc.* **1926**, 498-9.—Dilatometric measurements with chloral hydrate, with "liquid paraffin B. P." as the indicating liquid showed that the hydrate suffers a change of vol at 32°; densimeter expts. showed a complete absence of a break in the vapor pressure curve in the vicinity of 32°; thus the change which occurs at 32° probably does not correspond to a change in modification but marks the commencement of the dissociation of the hydrate. C. J. WEST

Hydroxymethyleneketones. FRICH BENARY, HANS MEYER AND KURT CHARLUS. *Ber.* **59B**, 108-12 (1926).—Compds. of the type $RCOCH:CHOH$ are not, with the exception of the 1st member of the aliphatic and of the aromatic series, as unstable as has hitherto been assumed (cf. Couturier and Vignon, *C. A.* **4**, 1093). *Hydroxymethylenemethyl Et ketone* (Et β -hydroxyvinyl ketone), obtained in about 80% yield from $MeCOEt$, HCO_2Et and Na in Et_2O , m. 73°, gives a violet color with alc. $FeCl_3$ even when $NaOAc$ is previously added, $b.$ 145-8°, sublimes *in vacuo*, is decompd. by hot dil. alkali into $MeCOEt$ and HCO_2H , titrates as a 100% enol by the Meyer Br method; its Na salt in H_2O at once gives with $PhNH_2 \cdot HCl$ the aniline deriv., $EtCOCH \cdot CHNHPH_2$, m. 128°, and with PhN_2Cl a benzeneazo deriv., yellowish, m. 137-8°, sol. in concd. H_2SO_4 with dark red color; as it gives no color with $FeCl_3$ it is supposed to have the aldehyde structure, $EtCOC(CHO) \cdot NNHPH_2$. *Hydroxymethylenemethyl Pr ketone*, mobile oil b_{16} 54°, rather quickly thickens and turns red in the air or a desiccator, gives a strong red color with alc. $FeCl_3$, is easily hydrolyzed by cold $NaOH$. *Et γ -hydroxymethylenemethyl α,α -diethylacetate*, from HCO_2Et and $AcCEt_2CO_2Et$, oil of aromatic odor, $b.$ 121°; *Cu salt*, blue-green, m. 76°; *aniline deriv.* yellowish, m. 70°. *Hydroxymethylenemethyl p-tolyl ketone*, light yellow, m. 40-1°, gives a red color with $FeCl_3$, slowly deliquesces to a viscous red oil in the air or a vacuum desiccator, is stable for a long time in sealed vessels; *Cu salt*, light green, m. about 218° (decompn.); *aniline deriv.* yellowish, m. 164-5°. "benzeneazo deriv." orange-yellow, m. 144°, forms a phenylhydrazone, orange-yellow, m. 161-2°; *1-phenyl-5-p-tolylpyrazole*, from the ketone and $PhNHNH_2$ on the H_2O bath, m. 94°. *ω -Hydroxymethylene-p-methoxyacetophenone*, light yellow, m. 50-1°, gives an intense red color with alc. $FeCl_3$; *Cu salt*, olive-green, m. 192-4°; *anilide*, light yellow, m. 158°; "benzeneazo deriv." orange, m. 136-7°, gives no color with alc. $FeCl_3$ and forms a phenylhydrazone, golden yellow, m. 218-9°; *1-phenyl-5-p-methoxyphenylpyrazole*, m. 90-1°. *Hydroxymethylenemethyl α -naphthyl ketone*, light yellow oil which cannot be distd. without decompn.; *Cu salt*, gray-green, m. 165-8°; *aniline deriv.*, light yellow, m. 116-8°. C. A. R.

The highest melting saturated acids (lignoceric and hexacosanic acid) of peanut oil. D. HOLDE AND N. N. GODBOLE. *Ber.* **59B**, 36-40 (1926).—The difficulty en-

countered by previous workers in obtaining pure lignoceric acid (I) from peanut oil and the different m. ps. of I which they report are due to the presence, hitherto not observed in peanut oil, of an acid $C_{26}H_{50}O_2$ (II). Bv distn in a high vacuum of the "crude arachic acid" and by a modified fractional pptn of the high melting acids with LiOAc (using $EtOH \cdot CHCl_3$ instead of $EtOH$ as the solvent) H and G obtained, together with pure I, m. 80.5–1.0°, small amts (actually isolated, 0.01%; amt estimated present, 0.1–0.2%) of II, m. 78.5–9.0°; with which of the known "cetotic acids" II is identical is a question reserved for a later paper. C A R

Isoboleic acid, and other fatty acids formed in the distillation of 10-hydroxystearic acid. V. VESELY AND H. MAJTL. *Chem. Listy* 19, 315–56 (1925), *Bull. soc. chim.* 39, 230–48 (1926).—Michel, Constantin and Saytzeff (*J. prakt. Chem* [2] 37, 269) observed the formation of a mixt. of unsatd. fatty acids during the distn of 10 hydroxy stearic acid under 160–200 mm. In their opinion this mixt. is composed of ordinary oleic acid and a solid isomer, which they termed isoleic acid. The latter is not the same as elaidic acid. From theoretical considerations V. and M. conclude that splitting off a mol. of H_2O from 10 hydroxystearic acid should lead to the formation of the 4 following acids: $\Delta^{9,10}$ -oleic acid (I), its *trans*-stereoisomer (ordinary elaidic acid) (II), *cis*- $\Delta^{10,11}$ -oleic acid (III), and its *trans*-isomer, isoleic acid (IV). It was found that the distillate contains a eutectic mixt. of II and IV, m. 35.6°, and a liquid soln. of I and III. F C. KRACEK

Octadecenic acids. AD. GRÜN AND WALTER CZERNY. *Ber.* 59B, 54–63 (1926).— β - $C_{10}H_7SO_3H$ (I) has been found to catalyze the formation of olefinic acids from HO esters (C. A. 14, 3416). In these cases, however, the olefinic acids were not isolated and their formation was shown only indirectly (detn. of HO, I nos., etc., of the products before and after the reaction). The suitability of I for this purpose has now been studied with a homogeneous compd. of known structure, viz., Et 12 hydroxystearate (II); this, in the presence of I, readily loses H_2O almost quant. and yields a mixt. of *cis*- and *trans*- $\Delta^{12,13}$ -octadecenic acids (III), whose structure is established by converting them into the acetylenic acids and oxidizing the latter (C. A. 20, 301). The II, prepd. by incomplete hydrogenation of castor oil to avoid reduction of the HO group (5 kg. oil with 1.5% Ni on a carrier hydrogenated at barely 80° for 3 hrs. until it was about 75% satd.) and esterified directly with 2% alc. HCl, m. 51–13°. Heated 1 hr. at 220° with 2% I and boiled in alc. until the partly saponif. product is completely converted back into the ester, it yields quant. the *Et* ester of III as a moderately viscous oil, b_D^{20} 18.4°, also obtained in 70% yield from the hydroxystearic acid boiled with $SOCl_2$, freed from the excess of $SOCl_2$ *in vacuo*, dried over P_2O_5 and KOH, dropped into alc., dild. with petroleum ether, washed free of mineral acids and distd. *Elaidic acid form* (IV) of III, m. 39.7–40.1°, solidifies 39.5°, b_D^{20} 19.6° (yield, about 60%). *Oleic acid form* (V) of III, sepd. from IV by fractionation of the Pb salts from alc. contg. AcOH, only liquid with the viscosity of oleic acid, m. (after standing 21 hrs. at 0°) 9.8–10.1°, solidifies 8.2°, b_D^{20} 19.6°; 10 g. shaken 3 min. at 25° with 5 g. HNO_3 (d. 1.4) and 1 g. Hg, then 1 min. more after 20 min. and allowed to stand 2 hrs. gives about 40% IV. $\Delta^{12,13}$ -Dibromooctadecenic acid (VI), from III and Br in petroleum ether below 3.5°, yellowish oil, does not cryst. at -20°, gives with boiling alc. KOH a viscous liquid consisting apparently of bromooctadecenic and octadecenic acid (neutralization no. 154.6, Br 20.6%). *Et* ester of VI, from the *Et* ester of III, oil; boiled 2 hrs. with 2 N alc. KOH and re-esterified with alc. HBr it yields *Et* 12-(or 13)-bromo $\Delta^{12,13}$ -octadecenate, b_D^{20} 19.3–5°; 3 parts of this evapd. with 2 parts cone. KOH and heated 10 hrs. at 180° gives $\Delta^{12,13}$ -octadecenic acid, m. 34.2°, which with alk. $KMnO_4$ and CrO_3 yields dodecanedioic acid, m. 123.2°, and capronic acid, with smaller amts. of undecanedioic acid and valeric acid. C A R

Addition products of iodine monobromide and hypoiodous acid to unsaturated compounds. II. D. HOLDE AND A. GORGAS. *Ber.* 59B, 113–5 (1926), cf. C. A. 19, 2637.—In continuation of the earlier work, H. and G. have succeeded in raising the yield of pure IBr derivs. of unsatd. acids prepd. according to Hannus from about 50% to 74–97% and have thus been able to bring the results of synthesis into better harmony with the quant. course of titrimetric analyses by the Hannus method. The degree of purity of the products has also been raised. The Ca salts of the IBr and HOI addn. products of erucic (I), oleic (II) and linolic acid (III) were prepd. by pptg. alc. solns. of the alkali salts with $CaCl_2$; those of the BrI derivs. are solid, white, cryst. and yet sticky; the stickiness of these salts, which are easily sol. in C_6H_6 and insol. in petroleum ether, could be greatly diminished by pptg. from C_6H_6 with alc. but not completely removed by washing with Me_2CO . The salts are quite stable towards light and air. The Ca salts of the HOI derivs. are likewise solid and sticky but even at a low temp. have a

glassy transparency, are non-cryst. and not sol. even in hot petroleum ether. Attempts to prep. TI salts of the addn. products by titration with TIOH failed on account of pptn. of TII on addn. of the aq. TIOH to the solns. in 96% alc. With I and III the I no. detn. according to Hanus was carried out in AcOH instead of CHCl_3 and the addn. products were accordingly extd. with petroleum ether instead of CHCl_3 . Iodobromobenzoic acid (97% yield), m. 37-8°; *Ca salt*, darkens 120°, m. 136° (decompn.). Diiododibromostearic acid, m. 77.8° (yield, 62% from petroleum ether, 74% from Et_2O); *Ca salt*, turns brown 100°, m. 115° (decompn.). *Ca iodohydroxystearate*, m. 190-4° (decompn.). Iodo-hydroxybenzoic acid; *Ca salt*, m. 184-8° (decompn.). Diiododihydroxystearic acid; *Ca salt*, gradually liquefies on heating. C. A. R.

Relative ease of 1,4- and 1,6-addition. E. P. KOHLER AND F. R. BUTLER. *J. Am. Chem. Soc.* 48, 1036-48 (1926).—For some reason inherent in the nature of long conjugated systems 1,6-addn. does not take place as easily as 1,4-addn. $\text{CH}_2(\text{CO}_2\text{H})_2$ (90 g.) and 60 g. $\text{CH}_2:\text{CHCHO}$ in 200 g. $\text{C}_6\text{H}_6\text{N}$ give 30 g. pure $\text{CH}_2:\text{CHCH}:\text{CHCO}_2\text{H}$, m. 72°; the Me ester (I) b_{25} 77-80° (64% yield). I (25 g.) and 55 g. $\text{CH}_2(\text{CO}_2\text{Me})_2$ are condensed by MeONa, giving 36 g. *tri-Me 3-pentene-1,1,5-tricarboxylate*, b_{11} 147-50°, and 1.5 g. of an oil, b_{11} 151-60°; the structure of the main fraction was established by decompn. of the ozonide. $\text{CH}_2(\text{CO}_2\text{Me})_2$ and Me sorbate give 62% of *tri-Me 2-methylpentene-1,1,5-tricarboxylate*, b_{10} 155°, b_{23} 185°. The reaction is reversible. Among the decompn. products of the ozonide is *propane-1,1,2-tricarboxylic acid*, isolated as the *tri-Me ester*, b. 127-31°, whose *hydrazide* m. 208° (decompn.). There was also isolated from the decompn. products a small amt. of a *compd.* $\text{C}_{11}\text{H}_{14}\text{O}_7(?)$, b. 164-7°; it reduces $\text{NH}_4\text{OH}\cdot\text{AgNO}_3$ but not fuchsin. I and PhMgBr give about 75% of β -phenyl- β -vinylpropionophenone, b_{10} 190°, oxidized by KMnO_4 in Me_2CO to $\text{BzCH}_2\text{CHPhCO}_2\text{H}$, m. 150°. There is also formed a 1,2-addn. product, which could not be purified but on oxidation with CrO_3 in AcOH gave BzPh and BzOH . Me β -phenylcinnamylideneacetate, m. 49°, formed by eliminating H_2O from $\text{PhCH}:\text{CHC}(\text{OH})\text{PhCHCO}_2\text{Me}$. This does not react with $\text{CHNa}(\text{CO}_2\text{Me})_2$ but with PhMgBr gives 40% of 1,3,5,5-tetraphenyl-1,3-pentadiene-5-ol, m. 121°; the concd. H_2SO_4 soln. is red by transmitted, deep blue by reflected light. A $\text{MeO}\%$ soln., satd. with HCl, gives triphenylstyryllane, m. 158°. C. J. WEST

Preparation of ethylene bromohydrin. F. H. McDOWALL. *J. Chem. Soc.* 1926, 499-500.—In the prepn. of $\text{HOCH}_2\text{CH}_2\text{Br}$ the Br is dropped from a small, finely pointed buret down a guide-tube of small bore, the lower part of which reaches to the bottom of the reaction vessel and is placed as far as possible from the C_2H_4 inlet. With an efficient stirrer the Br is dissolved by the H_2O before contact with the C_2H_4 is possible. The yields are good and the quantity of C_2H_4 used is slightly in excess of that absorbed. C. J. WEST

The heating of ethylene oxide and the mean temperature at which decomposition occurs. E. PEYTRAL. *Bull. soc. chim.* 39, 206-14 (1926); cf. C. A. 12, 579.—When ethylene oxide vapor is passed rapidly through a hot tube there result H_2O , AcH and a gas consisting of CO (44.7%), H (28.3%), CH_4 (15.0%), C_2H_2 (5.0%) and C_4H_2 (7.0%). The primary reactions are: (1) $4\text{CH}_2.\text{O}.\text{CH}_2 = 4\text{H}_2\text{CO} + \text{C}_4\text{H}_2$; (2)

$\text{CH}_2.\text{O}.\text{CH}_2 = \text{H}_2\text{O} + \text{C}_2\text{H}_2$; (3) $\text{CH}_2.\text{O}.\text{CH}_2 = \text{AcH}$. The secondary reactions are

(4) $\text{AcH} = \text{CO} + \text{CH}_4$; (5) $\text{H}_2\text{CO} = \text{CO} + \text{H}_2$; (6) $\text{C}_2\text{H}_2 + \text{H}_2 = \text{CH}_2.\text{CH}_2$. Of 100 mols 56 decomp. according to equation 1, 10 according to equation 2 and 34 according to equation 3. The decompn. is exothermic and calcs. based on the heats of the several reactions and the speed with which the gas traverses the tube show that at the moment when decompn. takes place the temp. of the gas rises during an interval of about 0.002 sec. from approx. 571° to 1200°. REYNOLD C. FUSON

Organic halogen oxides: oxidation of 1-chloro-1-heptene and 2-chloro-2-octene with perbenzoic acid. N. PRILESHAIEV. *Ber.* 59B, 194-8 (1926); cf. C. A. 6, 2407. From 37 g. 1-chloro-1-heptene, b_{73} 149-50°, oxidized 25 days with BzO_3H (4.5 g active O) is obtained 13 g. of a product b_{80} 93-5°, d_{16}^{20} 0.9874, n_D^{20} 1.4370, having the compn. of chloroheptene oxide, $\text{C}_7\text{H}_{11}\text{CH}.\text{CHCl}.\text{O}$; it has an intense enanthal and geraniol odor, is

oxidized by 1% KMnO_4 , forms a mirror with Tollens' reagent and reddens fuchsin- SO_2 boiled with CaCO_3 , it yields the aldehyde *alc.*, $\text{C}_6\text{H}_{11}\text{CH}(\text{OH})\text{CHO}$, m. 98.5-9.5°. 2-chloro-2-octene, from $\text{C}_8\text{H}_{17}\text{COMe}$ with PCl_5 and subsequent treatment with alkali, b_{80} 84-6°, d_{16}^{18} 0.8923, n_D^{16} 1.4424; 90 g. with BzO_3H (16 days) yields 25 g. 2-chlorooctene-2-oxide, b_{21} 81-2°, d_4^{20} 0.9755, d_4^{16} 0.9609, n_D 1.4359, slowly oxidized by 1% KMnO_4 and

contains C 50.58, H 9.28, Ca 11.41%. The above results indicate that, contrary to hitherto almost universal opinion, chloro oxides with the Cl in the oxide ring are quite stable compds. which with alkalis yield chiefly in the normal way α -aldehyde or α -ketone alcs. C A R

Resolution of *dl*-alanine and the formation of *trans*-2,5-dimethylpiperazine. F. B. KIPPING AND WM. J. POPE. *J. Chem. Soc.* **1926**, 494-7. *dl*-Alanine is resolved by means of the *d*-hydroxymethylenecamphor deriv. of the Et ester, which m 108.9, $[\alpha]_{\text{H}_2\text{O}}^{25^\circ}$ 256°; it is decompd. by distg with steam in the presence of concd HCl. The reduction of *l*-lactimide with Na and EtOH or AmOH gave only the optically inactive *trans*-2,5-dimethylpiperazine. The lactimide was not reduced by colloidal Pd or Pt, by Ca or CaH₂ and EtOH or by Al-Hg in dil EtOH. No evidence is thus obtainable as to whether inactive lactimide is the *dl*- or *cis*-compd., or the internally compensated or *trans*-compd. C J WEST

Molecular rearrangement of α -keto alcohols. A FAVORSKII. *Bull. soc. chim.* **39**, 216-20 (1926).—By heating alc EtCH(OH)COPr with a few drops of concd H₂SO₄ in a sealed tube at 120-30° EtCOCH(OH)Pr is obtained. Similarly, MeCH(OH)COEt, MeCH(OH)COCMe₃ and Me₂C(OH)COCHMe₂ are transformed into MeCOCH(OH)Et, MeCOCH(OH)CMe₃ and MeCOCOCH(Me)CHMe. Me₂C(OH)COCMe₃

(I) goes to MeCOC(OH)MeCMe₃. The structure of the products has been proved by treatment with MeMgI and subsequent oxidation of the resulting glycols. The case of I indicates that an ethylene oxide is an intermediate in the rearrangement, which proceeds as follows: $\text{RCOCH(OH)R} \rightarrow \text{RC(OH)OCHR} \rightarrow \text{RCH(OH)COR}$ B Z CH-

(OH)Me, which is similarly transformed into PhCH(OH)Ac, is found to undergo the same rearrangement under the conditions of alc fermentation. The mechanism of alc. fermentation of sugars is discussed. RENOLD C FUSON

The preparation of propylidene- and of isoamylidene-acetone with the intermediate formation of the corresponding ketols. PASTUREAU AND ZAMENHOF. *Compt. rend.* **182**, 323-5 (1926).—Far higher yields of EtCH·CHCOMe (I) and Me₂CHCH·CH·CHCOMe (II) than those obtainable by the method of Barbier and Bouveault (*Compt. rend.* **118**, 198 (1894), **120**, 1269 (1896)) were obtained by a new method. This is based on that of Grignard (*C A* **1**, 1389; **19**, 1247) and consists essentially of adding the mixt. of aldehyde and Me₂CO in cold Et₂O by aq. NaOH, isolating the intermediate ketol and dehydrating the latter. This method gave 3-hexanolone, EtCH(OH)CH·CHCOMe, in 60% yield, colorless, odorless liquid, b₂₅ 90°, d₄¹⁵ 0.951, n_D¹⁶ 1.4368, has great tendency to form I, particularly when rectified *in vacuo*, and 2,4-methylheptanolone, Me₂CHCH₂CH·CH(OH)CH₂COMe in 70% yield, colorless, mobile liquid, b₇₅ 75°, d₄¹⁵ 0.9247, n_D²⁰ 1.4366, can be rectified *in vacuo* without decompn. Among various methods of dehydration tried, the best results were obtained with that of Loequin (*C A* **17**, 2559). Transformation of the ketol was easily accomplished and 90% yields of I and of II were obtained. The yields of I and of II, based on the EtCHO and Me₂CHCH₂CHO, were 54% and 63%, resp. C C DAVIS

Irreversible reduction of organic compounds. II. The dimolecular reduction of carbonyl compounds by vanadous and chromous salts. J. B. CONANT AND H. B. CUTTER. *J. Am. Chem. Soc.* **48**, 1016-30 (1926), cf. *C A* **19**, 204. CrCl₃ in aq. or EtOH soln is without effect at 25° on representative aliphatic aldehydes and ketones, aromatic ketones, satd. and unsatd. acids and esters, alcs, C₆H₄ or diphenylbutadiene. Typical aromatic aldehydes, α,β -unsatd. aldehydes, PhCH·CHBz and certain other α,β -unsatd. ketones are reduced by CrCl₃ and VCl₃ with the formation of dimol products. Me₂C·CHAc is not reduced. The amt. of monomol reduction, if any, must be very small. It seems probable that the dimol reduction process proceeds through an addn. product of the CO compd. and the inorg. acid present and is analogous to the reduction of the halochromic salts of arylcarbmols. PhCH·CHAc (20 g.), reduced by an excess of EtOH-CrCl₃, gives 5 g. of a product m 161° (Harries, *Ber.* **29**, 381, 2121 (1896)). PhCH·CHBz is best reduced by VCl₃ in Me₂CO; there results 45% of low melting dimol. product (I), 35% of high melting product (m 258-60°), corresponding to the product obtained by Harries (*Ann.* **296**, 329 (1897)), 10% of unchanged ketone and 10% of non-cryst. oils. I is α,δ -dibenzoyl- β,γ -diphenylbutane, n. 194°, b₅ about

360° giving I and a few % of the high melting isomer. Both isomers give the *dibromide*, $C_{30}H_{22}OBr_2$, m. 171°. I and EtONa give *2,4,5-triphenyl-1-benzoylcyclopentene*, m. 123°, reduced by Zn in AcOH to the *pentane deriv.*, m. 148–51°. *p*-MeOC₆H₄CHO (20 g.) gives 6 g. isohydroanisoin, m. 101°. BzH and aq. acidic VSO₄ give a mixt. of hydrobenzoin and isohydrobenzoin (90% yield); no trace of PhCH₂OH or PhMe was found. CH₂:CHCHO with VSO₄·7H₂O gives 30% of divinylglycol; when a purple soln. of VSO₄ contg. an excess of H₂SO₄ and ZnSO₄ was employed the yield of divinylglycol was only 9%; 27% of the material was changed into a *compd.*, C₁₂H₁₈O₃, b. 167–8°, n_D^{20} 1.14438, does not yield a cryst. bromide, does not react with NaHSO₃ or H₂-NCONHNH₂. The recovered CH₂:CHCHO gave a very faint test for EtCHO. MeCH:CHCHO gives 18% of dipropionylglycol and other products which were not obtained pure. PhCH:CHCHO gives only 5% of diphenylvinylglycol. C. J. WEST

Mutarotation of mixtures of molybdates and of ethyl malate. Probable constitution of molybdomalic derivatives. E. DARMOIS. *Compt. rend.* **182**, 455–7 (1926).—A continuation of previous work (C. A. **17**, 2564). Di-Et malate does not react with MoO₃ or molybdates in the cold, but at 100° there is considerable reaction; with, however, reduction of MoO₃, particularly in acid soln. Polarimetric detns. were made most successfully at about 80°. By using the proportions MoO₃/2C₄H₆O₆Et₂ and 2MoO₃/C₄H₆O₆Et₂, which correspond to 2 series of molybdomalates and the compds NaH₂(MoO₄)₂, Na₂H₂(MoO₄)₂, Na₂MoO₄ and Na₂MoO₄ + NaOH, and following the reaction by the progressive changes in rotation, it was shown that, as with tartrates, the reaction is rapid only with molybdates of greater basicity than NaH₂(MoO₄)₂ and that this rate is also a function of the proportion: ester/MoO₃ and of the total concn. The changes in rotation also indicate that C₄H₆O₆Et₂ is sapon. in 2 stages: (1) formation of C₄H₆O₆HEt which then combines with MoO₃ to give the *l-compd.* MoO₃·2C₄H₆O₆NaEt (corresponding to Na₂MoO₄·2C₄H₆O₆Et) and (2) subsequent sapon. of the 2nd Et group, giving the *d-compd.* 4MoO₃·2C₄H₆O₆Na₂. Since it has already been shown (C. A. **19**, 786) that the formation of complexes requires the presence of 2 OH groups in α -positions, the formula of *l* Et malate must be HO₂CCH(OH)CH₂CO₂Et, and its *addn compd. with MoO₃* must be bound by the 2 free OH groups. C. C. DAVIS

Tartaric acids. LOUIS LONGCHAMRON. *Compt. rend.* **182**, 473–4 (1926).—Though Pasteur discovered inactive tartaric acid, no properties were given, and it has never since been isolated in pure cryst. form. *d*-Tartaric acid was boiled with a large excess of aq. NaOH, acidified with HCl, the liberated acids were pptd. by CaCl₂, the Ca tartrates decompd. by H₂SO₄ (1:1) and the liquid was concd. On cooling the *dl*-acid crystd. in long prisms, and on further concn. and repeated crystn. *hydrated inactive tartaric acid*, C₄H₆O₆·H₂O, was obtained, triclinic plates, parameters, $a:b:c = 0.6424:1:0.7925$ and angles $\alpha = 90^\circ 16'$, $\beta = 96^\circ 31'$, $\gamma = 75^\circ 46'$, d. 1.668, m. above 120° in its H₂O of crystn. When inactive C₄H₆O₆·H₂O was crystd. from strong H₂SO₄ or better from H₂O above 50°, crystals of *anhyd. inactive C₄H₆O₆*, totally different from the preceding, were obtained, i. e., octahedrons belonging to the orthorhombic system parameters, $a:b:c = 0.9467:1:1$, d. 1.737, m. 159–60°. *Active hydrated acid*. Solv. curves showed that this is stable below –5°, but that it may be easily obtained above 0° by inoculating a supersatd. soln. of the crystd. hydrate described above or with *l* l tartrate. Its compn. was C₄H₆O₆·H₂O, orthorhombic crystals similar to the preceding hydrate, parameters $a:b:c = 0.4716:1:0.5304$, d. 1.582, dehydrates rapidly at room temp. The existence of the hydrate explains certain anomalies described in the literature. C. C. DAVIS

Urea and guanidine derivatives of the sulfofatty acids. III. RUDOLF ANDREASCH. *Monatsh.* **46**, 23–30 (1925); cf. C. A. **19**, 237. —Guanidine-HCl and MeCHBrCOBr give α -bromopropionylguanidine, analyzed as the H₂PtBr₆ salt, red. K₂SO₃ gives *guanido- α -sulfopropionic acid*, sinters 295°, m. 306° (decompn.); the mol. wt. in boiling H₂O normal. α -Bromobutyrylguanidine, analyzed as the HBr salt, and the H₂PtBr₆ salt, garnet-red; K₂SO₃ gives *guanido- α -sulfobutyric acid*, sinters 300°, m. 314° (decompn.), mol. wt. in boiling H₂O normal. *Guanido- α -sulfoisobutyric acid*, m. 168°, the intermediate *guanidine* was analyzed as the H₂PtBr₆ salt, garnet-red. MeCHBrCONH₂ and (NH₄)₂SO₃ in H₂O give *NH₄ propionamide- α -sulfonate*, tablets. *K butyramide- α -sulfonate*, needles with 1H₂O; *NH₄ salt*, prisms. *NH₄ isobutyramide- α -sulfonate*, K₂SO₃ has only a reducing action on bromodimethyldiluturic acid, the Br being replaced by H (or K). C. J. WEST

Quantitative study of the action of mercury salts on the dialkylbarbituric acids. I. Phenylethyl, diethyl and butylethyl derivatives. PAUL FLEURY. *Bull. chim. chim.* **37**, 1656–68 (1925). —HgSO₄ in acid soln., poured in excess into aq. or alc. phenylethylbarbituric acid (I) gives a ppt. with the compn. about 2.5HgO:3 I. This can be used

and dissolves in about 50 parts H_2O at room temp. **I** with $ZnCl_2$ in hot Ac_2O gives the penta-Ac deriv., $[\alpha]_D^{20} -15.9^\circ$ (C_6H_5N), readily hydrolyzed back to **I** by 0.25 mol. alc. $NaOEt$. Shaken in C_6H_5N with 8.5 mols. Ac_2O until it dissolves (about 36 hrs.), **I** gives 63% of a tetra-Ac deriv. (**IV**), begins to sinter about 85° , m. around 100° , mol. wt. in freezing H_2O 400-3, $[\alpha]_D^{23} -6.9^\circ$, sol. in 15 parts H_2O at room temp., reduces Fehling soln. only after some boiling, slowly and continuously evolves N in aq. Me_2CO with acidified KNO_3 , showing that the NH_2 group is not acetylated, is hydrolyzed back to **I** by $NaOMe$ in $MeOH$, yields with $AcCl$ in C_6H_5N 85% of the penta-Ac deriv. and 3.9 g. with 1.5 mols. $BzCl$ and 1.5 mols. C_6H_5N in $CHCl_3$ (distd. from P_2O_5) gives 2.5 g. tetraacetyl-d-glucose-benzoylurea, sinters around 195° , m. $211-2^\circ$, $[\alpha]_D^{20} -29.7^\circ$ (C_6H_5N), does not reduce Fehling soln. even on boiling (probably on account of its slight soly in H_2O). Tetraacetylheronal(?) -glucoside (1.5 g. from 8 g. **IV**, 1 mol. $Et_2C(COCl)_2$ and 2.2 mols. C_6H_5N kept 50 hrs. at 50° in $CHCl_3$), $[\alpha]_D^{19} -20.2^\circ$ (C_6H_5N), sinters 165° , m. $169-70^\circ$, becomes smeary when rubbed with $NaOH$ and then dissolves, at once gives a white amorphous ppt. in hot dil. alc. with $Hg(NO_3)_2$, reduces Fehling soln. only after some boiling and not more rapidly if previously heated with acids. Triacetyl-l-arabinose-urea (88% from **III** with Ac_2O in C_6H_5N), $[\alpha]_D^{24} 45.9^\circ$, reduces Fehling soln. only after some boiling, begins to sinter 210° , m. 212° (decompn.), readily hydrolyzed back to **III** by 0.25 mol. $NaOMe$ in $MeOH$. Pentabenzoyl-d-glucosethiourea (2.8 g. from 2.4 g. **II** in C_6H_5N with $BzCl$), $[\alpha]_D^{18} 45.0^\circ$ (C_6H_5N), m. 205° , hydrolyzed back to **II** by 0.25 mol. $NaOMe$. Octabenzoyl-di-[d-glucose]-urea (5.5 g. from 3.3 g. **I** with 13.6 mols. $BzCl$ in C_6H_5N), generally seps. with 1 mol. $EtOH$, begins to sinter about 140° , m. around 150° ; dil. solns. in $CHBr_3$ show no appreciable depression in the m. p., 2% solns. only a very slight lowering, and under the ultramicroscope the Tyndall effect can be distinctly observed; 6 g. in $MeOH$ satd. with NH_3 at 0° , shaken at room temp. until dissolved, again satd. with NH_3 at 0° and kept 12 hrs. at room temp. gives 1.5 g. di-[d-glucose] urea, needles or columns with 2.5 H_2O , $[\alpha]_D^{17} -34.3^\circ$ to -35.8° (H_2O), mol. wt. in freezing H_2O 350-78, turns brown about 205° , carbonizes around $235-45^\circ$. Hexabenzoyl [di-l-arabinose]-urea (2.1 g. from 2 g. **III**), needles with varying amts. of $EtOH$ of crystn., $[\alpha]_D^{19} 163.0^\circ$ (C_6H_5N), sinters 250° , m. 260.1° (decompn.), reduces Fehling soln. only after energetic acid hydrolysis ($AcOH-HCl$); 3 g. in aq. C_6H_5N with NH_3 gives 0.2 g. di-[l-arabinose]-urea, $[\alpha]_D^{19} 62.1^\circ$ (H_2O), becomes discolored 205° , decomps. around 227° .

C. A. R.

Specificity of the α -glucosidase from yeast. BURCKHARDT HELFERICH, WILHELM KLEIN AND WILHELM SCHAFER. *Ber.* 59B, 79-86(1926).—It has hitherto not been possible, because the necessary derivs. of α -Me glucoside (**I**) were not available, to determine whether the ability of α -glucosidase (**II**) to split off the glucosidic Me group is affected in the same way as that of β -glucosidase by changes on the 6-C atom (cf. Fischer, *C.* 14, 1688, and earlier papers). In the present paper is described a method for changing the HO on the 6-C atom of **I** in various ways. The ethers of Ph_3COH react with PCl_5 or (usually less satisfactorily) with PBr_5 according to the equation $ROCPH_3 + PCl_5 \rightarrow RCl + Ph_3CCl + POCl_3$, and as no HCl is formed it seemed possible that ethers sensitive to acids at other points in the mol. (especially that of **I**) might in this way be converted into the corresponding chlorides if the free HO groups were temporarily protected by acylation. Such proved to be the case, and a study of the action of **II** from yeast on the compds. obtained in this way showed that it is more sensitive than the β -glucosidase to changes in the substrate. 2,3,5-Triacetyl-6-triphenylmethyl- α -methylglucoside (**III**), m. 136° , is obtained in 69% yield from **I** heated 2 hrs. on the H_2O bath with 1 mol. Ph_3CCl in dry C_6H_5N and then allowed to stand 18 hrs. at room temp. with 9 mols. Ac_2O ; 20 g. of this is warmed a few min. with 1 mol. PCl_5 , freed from as much as possible of the $POCl_3$ at 40° in *vacuo*, extd. with Et_2O , washed with H_2O and $KHCO_3$, dried with Na_2SO_4 , evapd., satd. in $MeOH$ with NH_3 at 0° , allowed to stand 5 hrs. at room temp., evapd. in *vacuo*, extd. with 50 cc. H_2O , evapd. to dryness in *vacuo*, extd. with 50 cc. cold $AcOEt$, evapd. in *vacuo*, freed from most of the $AcNH_2$ still present by sublimation in a high vacuum and acetylated in C_6H_5N with 8.5 g. Ac_2O , giving 3.7 g. 2,3,5-triacetyl- α -methylglucoside 6-chlorohydrin (**IV**), sinters 95° , m. $98-9^\circ$, $[\alpha]_D^{18} 163^\circ$ (C_6H_5N), reduces Fehling soln. only after hydrolysis with $AcOH-HCl$; with aq. Br_2 (OH)₂ at room temp. it gives 40% of α -methylglucoside 6-chlorohydrin (**V**), sinters 102° , m. $110-2^\circ$, $[\alpha]_D^{21} 139.72^\circ$, reduces Fehling soln. only after hydrolysis with acids. *Br* analog (**VI**) of **IV** (yield, 51%), m. 117° , $[\alpha]_D^{19} 125.8^\circ$ (C_6H_5N). *Br* analog (**VII**) of **V**, from **VI** with NH_3 and $MeOH$ (yield, 6.5%), sinters 126° , m. $129-30^\circ$, $[\alpha]_D^{19}$

107.4° (H₂O). *Anhydro-α-methylglucoside* (VIII), prepd like the β-compd (Fischer, C. A. 6, 1295) in 75% yield, very hygroscopic, m. 89–95°, $[\alpha]_D^{20}$ 40.3°, has a very bitter taste. *Triacetyl-α-methyl-d-isorhamnoside* (50% from VI in 50% AcOH and a drop of PtCl₄ slowly treated on the H₂O bath with Zn dust), m. 75°, $[\alpha]_D^{20}$ 159.2° (CHCl₃), hydrolyzed quant. by NH₃ in MeOH to *α-methyl-d-isorhamnoside* (IX), m. 98–9°, b₁ 162–3°, has a sweetish taste. 6-Me ether (X) of I, b₁ 195–200°, $[\alpha]_D^{19}$ 127.9° (H₂O). II does not hydrolyze V, VII, VIII, IX or X.

Acetone-sugars. VII. Constitution of diacetonegalactose. KARL FREUDENBERG AND KARL SMEYKAL. Ber. 59B, 100–7 (1926); cf. C. A. 19, 1561—6 Me ether (I) of diacetonegalactose (II) (6 g. from 10 g. II refluxed with Na in Et₂O, evapd., al. lowed to stand 12 hrs. at 35° with MeI, freed from most of the NaI by pptn. with Et₂O distd. under 1 mm. and freed from unchanged II by treating with *p*-MeC₆H₄SO₂Cl in dry C₆H₅N at 35°), b_{0.5} 109–15°, $[\alpha]_{578}^{20}$ –66.6° (without solvent); 3 g. refluxed in 1% H₂SO₄ gives 1.6 g. *galactose 6-Me ether* (III), m. around 128°, $[\alpha]_{578}^{22}$ 114° in H₂O 5 min. after soln., 77° (const.) after 3 hrs., reduces Fehling soln.; *phenylhydrazone*, decomp. 182–3°, $[\alpha]_{578}^{17}$ 14.5° (C₆H₅N), shows no mutarotation; *osazone*, yellow, m. 201–5°, $[\alpha]_{578}^{17}$ 135° (C₆H₅N). Boiled 24–36 hrs. in H₂O with yellow HgO and CaCO₃ III gave *galactonic acid 6-Me ether* (IV), m. 156°, has an acid taste, can be titrated with NaOH and phenolphthalein, $[\alpha]_{578}^{18}$ –5.54° in H₂O 5 min. after soln., –10.2° (const.) after 8 days. The lactone was not isolated in cryst. form but, besides the change in rotation, further evidence of its formation is the fact that when 0.3598 g. IV in H₂O is twice evapd. to a sirup on the H₂O bath, taken up in cold H₂O and immediately titrated (phenolphthalein) a red color, persisting about 30 sec., is obtained with 1.5 cc. 0.2 N NaOH and this continues until 8.65 cc. (caled, 8.56) has been added, when the color is permanent even on boiling. *NH₄ salt* of IV, m. 185°, rotation in H₂O about 30°, *PhNHNH₂ salt*, m. 158–9°, $[\alpha]_{578}^{17}$ 4.7° (H₂O), forms an acid aq. soln. Heated with H₂NO₃ (d 1.15) 2.5 hrs. on the H₂O bath IV gives no trace of mucic acid (galactose under the same conditions gives 80%, and galactose Me ether gives IV and considerable (C₆H₅)₂). With Ag₂O in H₂O on the H₂O bath IV yields 43%, MeOCH₂CO₂Ag, further identified by converting it into the K salt and refluxing this in alc. in the presence of a little NaI, with *ω*-bromoacetoveratrone, which gave *ω*-[methoxyacetyloxy]acetoveratrone, m. 70°. This establishes the structure of IV as a 6-Me ether and that the 6-HO group in II is free. *Diacetonegalactosyl-6-dimethylamine*, from the MeC₆H₄SO₂ deriv. of II with alc. NHMe₂, at 100°, oil with the consistency of glycerol, b₁ 110–5°, $[\alpha]_{578}^{16}$ 85.78°; *methiodide*, $[\alpha]_{578}^{18}$ –32° (H₂O), converted by N H₂SO₄ at 70° into *galactosyl-6-trimethylammonium iodide*, crystals with 1H₂O, sinters 90°, decomp. 140°, $[\alpha]_{578}^{12}$ 65.3° (H₂O) after 5 min., 51.8° (const.) after 12 hrs. *Diacetoneglucose* (V), m. 102°, can be obtained in 45–55 g. yield from 65 g. *α*-glucose shaken 4–5 hrs. in 1.8 l. Me₂CO and 55 cc. concd. H₂SO₄. Assuming that in II the 1st Me₂CO residue is combined with the HO groups on C atoms 1 and 2, the 2nd can be only on C atoms 2 and 5 or 3 and 4, the latter structure (that of a (1,2)(3,4)-diacetone-*α*-galactose (1,5) with an amylene oxide ring) is given the preference by F. and S. Like II, V is formed from both the *α* and the *β* sugar, hence when galactose dissolves in Me₂CO-H₂SO₄ it must first form an equil. mixt. of the 2 forms which, as the acetonation proceeds, is shifted in favor of I form, the entering Me₂CO residues do not have a choice between a butylene and an amylene oxide but must react with whatever form is present and, unless all observations hitherto made on the tension of O-contg. rings are deceptive, the amylene oxide ring is preformed in the galactose itself. F. and S. believe that this view that II contains the galactose in the same form as in the free sugar and its natural derivs. also holds for other sugars. It would then follow, from the structure of the Me₂CO derivs., that free glucose has the butylene, fructose and probably xylose and arabinose the amylene oxide structure, while mannose and rhamnose (it will be shown in a later paper that the 1 HO group in the Me₂CO derivs. of rhamnose is free) would again be butylene oxides. (Oile and Berend (C. A. 1, 20, 1389) have reached the same conclusions as F. and S. as to the structure of II.

C. A. R.

Identity of isomaltose with gentiobiose. HENRY BERLIN. J. Am. Chem. Soc. 48, 1107–11 (1926).—The crude sirup, representing the unfermentable portion of the product obtained by the action of concd. HCl upon *d*-glucose as described by Fischer (Ber. 23, 3687 (1890)) and by Friedrichs (C. A. 8, 2153), upon acetylation, yields cryst. *β*-gentiobiose octaacetate in a yield corresponding to about 1 g. of gentiobiose per 100 g. of *d*-glucose. Evidence is presented that the disaccharide osazone which Fischer

obtained in low yield from such a sirup and named isomaltose osazone, is gentiobiose osazone.

C. J. WEST

Hexahexosan and trihexosan. P. CASTAN AND A. PICTET. *Helvetica Chim. Acta* **8**, 946-8(1925) (in French); cf. P. and Jahn, *C. A.* **17**, 270; P. and Stricker, **19**, 976.—Hexahexosan ($C_6H_{10}O_6$)₆ (I) is best freed from the higher polymers which cause it to give a violet color with I-KI soln. by repeated pptn. by alc.; it then gives a bright red color. In a mixt. the higher polymers react first when the I is added in small amts. When a red soln. is slowly warmed, it turns violet, then blue, and finally colorless; on cooling, the colors reappear in inverse order. $[\alpha]_D^{20}$ of I 173.2° (H_2O , c 2.89), mol. wt. 974 (calcd. 972). I can be filtered on collodion and is not pptd. by reagents for dextrans. Treated with AcBr according to Karrer, Nägeli, Hurwitz and Wälti (*C. A.* **16**, 64), 1 g. gave 0.5 g. heptaacetylmaltose (II) and 0.05 g. glucose, thus behaving like starch and the amyloses. Barley amylase, purified from maltase by pptn. by alc., gave at 25° in the absence of buffers, after 18, 24 and 48 hrs., 32.2, 36.3 and 42.3% maltose, resp. After 35 days at 25° emulsin gave barely 20% maltose, but no other definite product could be isolated although the soln. no longer gave a color with I. Attempts at polymerization failed. Trihexosan (III) gave 96.3% glucose on hydrolysis. After the action of amylase only maltose could be isolated, splitting occurring one-half as rapidly as in the case of I, contrary to the effect of emulsin (P. and Salzmann, *C. A.* **19**, 976). AcBr and 1 g. III gave 0.30-0.35 g. II and 0.13 g. glucose. M. HEIDELBERGER

Dihexosan and tetrahexosan. A. PICTET AND R. SALZMANN. *Helvetica Chim. Acta* **8**, 948-9(1925); cf. *C. A.* **19**, 976.—An analysis is given of dihexosan (I), obtained by the action of emulsin on trihexosan. Dissolved in concd. HCl and shaken with Ag₂CO₃ I yields maltose, identified as the osazone, also obtained from I and amylase. Acetylated as in the preceding abstr. I yielded β -octaacetylmaltose, and is, therefore, a maltose anhydride, like diamylase and maltosan. As a by-product in the prepn. of I tetrahexosan (II) is obtained, prisms, m. 260°, mol. wt. 647 (calcd. 648), $[\alpha]_D^{20}$ 162.6° (H_2O , c 2.92), apparently owing to repolymerization of the I by the emulsin. II is slowly attacked by amylase, yielding maltose. M. HEIDELBERGER

Amylose-octadextrin. PETER KLASON AND KNUT SJÖBERG. *Ber.* **59B**, 40-5 (1926).—See *C. A.* **20**, 1222. C. A. R.

Lignin. I. Lignin of pine wood. ALFRED FRIEDRICH AND JAKOB DIWALD. *Monatsh.* **46**, 31-46(1925).—The wood meal is freed from resins by extn. with EtOH-C₆H₆ for 7 hrs., and from gums by extg. 4 times with 5% NaOH at room temp. (36 hrs. for each extn.). After washing with H₂O, AcOH and then again with H₂O, the dried wood is mixed with an equal vol. of HCl (1 part HCl (d. 1.17) + 1 vol. H₂O) and allowed to stand for 48 hrs. The moist (acid-contg.) product is then heated with 10 parts 96% EtOH for 8-10 hrs., the ext. filtered, concd. to 1/3 of its vol. and pptd. with 10 parts H₂O, giving 8-10% of primary lignin (I), C₁₄H₃₀O₇(OMe)₆, light cocoa-colored powder very hygroscopic, begins to decomp. about 90°. Lignin prepd. from wood extd. with warm NaOH contains 1 less MeO group. Conc'd. solns. in org. solvents are deep brown but H₂O ppts. from these solns. a much lighter powder. I is sol. in NaOH but insol. in Na₂CO₃; the product obtained by allowing I to stand in warm 2 N NaOH for 2 hrs. contains but 3 MeO groups and is sol. in Na₂CO₃. After standing several hrs. in conc'd. HCl, I gives a product with only 16.5% MeO (I contains 21% MeO). Depending upon the mode of action of Br, reaction products with 4, 5 or 6 atoms Br are obtained; all are amorphous, red-brown products, decomp. about 100°; the mol. suffers considerable decompn. or change in the reaction. Warming I with 3% H₂O₂ on the H₂O bath gives a product approx. C₂₂H₃₈O₇(OMe)₃, amorphous light yellow powder, which has no reducing power and does not give the color reactions of I. In NaOH, shaken with Me₂SO₄, gives the compd. C₃₄H₅₂O₈(OMe)₆, yellow-brown, decomp. 110°. BzCl gives a compd. C₃₆H₄₆O₁₂(OMe)₆, light yellow. The color reactions are described. Mol. wt. detns. by the osmotic method of Barger-Rast give values of 565-795 for I and 524-625 for the oxidation product. C. J. WEST

Synthesis of dihydrochaulmoogric and dihydrohydnicarpic acids. II. C. R. NOLLER AND ROGER ADAMS. *J. Am. Chem. Soc.* **48**, 1080-9(1926); cf. Shriner and A. C. A. **20**, 172.—Cyclopentanone, b. 129° (cor.) (all temps. are cor.), n_D^{20} 1.4370, d_4^{20} 0.9502. Cyclopentanol, b. 139°, n_D^{20} 1.4530, d_4^{20} 0.9488. Cyclopentyl bromide, b. 135.6°, n_D^{20} 1.4882, d_4^{20} 1.3900; the Mg deriv. with gaseous HCHO gives 62.4% of cyclopentylcarbinol, b. 162-2.5°, n_D^{20} 1.4579, d_4^{20} 0.9313; with (CH₂)₃IO, γ -cyclopentylpropanol, b. 85.6°, n_D^{20} 1.4590, d_4^{20} 0.9137 (phenylurethan, m. 55.5-4°). (CH₃)₂CHMgBr and CHO(CH₂)₁₁CO₂Me give Me- μ -cyclopentyl- μ -hydroxytridecanoate (I), b. 205-10° m. 29-9.5°; the free acid, m. 70.5-1°. The low boiling fraction is Me- μ -hydroxytride-

anoate, m. 38–40° (phenylurethan, m. 73.5–4°); the free acid, m. 77–75°. A 2nd fraction contains the *pinacol* of *Me* λ -aldehydododecanoate, m. 58–9°. I is converted through the bromide and the unsatd. acid to μ -cyclopentyltridecanoic acid, m. 70–1°, identical with dihydrochaulmoogric acid; the amide of each m. 105.6°. *Me* κ -cyclopentyl- ϵ -hydroxyundecanoate, from cyclopentylmethyl bromide, Mg, and $\text{CHO}(\text{CH}_2)_8\text{CO}_2\text{CH}_3$, b₈ 175–80°; the free acid, m. 60–60.5°; by the above procedure there was obtained κ -cyclopentylundecanoic acid, m. 63–3.5°, identical with dihydrohydnoacarpic acid; the amide of each m. 114–5°. III. The synthesis of homologs of dihydrochaulmoogric and dihydrohydnoacarpic acids containing a cyclohexyl in place of a cyclopentyl group. G. S. HIERS AND R. ADAMS. *Ibid* 1089–93 — β -Cyclohexylethanol, b₆ 86.9°, b₁₀ 98–101°, n_D^{25} 1.4698, d_4^{25} 0.9165, in 53% yield from $\text{C}_6\text{H}_{11}\text{MgBr}$ and $(\text{CH}_3)_2\text{CO}$, the bromide, in 65% yield, b₆ 70–1°, n_D^{25} 1.4888, d_4^{25} 1.2069. With $\text{CHO}(\text{CH}_2)_8\text{CO}_2\text{Me}$ the Grignard reagent from the bromide yields 26% the *Me* ester, b₁ 192.8°, m. 35.6°, of κ -cyclohexyl- θ -hydroxyundecanoic acid, m. 76–7°. From this is prepd. as above cyclohexylundecanoic acid, m. 58–9°. μ -Cyclohexyl- μ -hydroxytridecanoic acid, m. 72.3°; *Me* ester, b₄ 212–7°. μ -Cyclohexyltridecanoic acid, m. 63–4°. C. J. WEST

Geometrical isomerism in the cyclohexane series. Action of phenylmagnesium bromide on cyclohexene oxide. P. BEDOS. *Bull. soc. chim.* 39, 292–305 (1926), cf. C. A. 19, 1702. — When cyclohexene oxide (I) is treated with PhMgBr and the reaction mixt. decompd. with H_2O in the presence of Et_2O , the chief product is cyclohexane 1,2-bromohydrin (II), b₈ 87–8°, d_4^{12} 1.402, n_D^{12} 1.528, phenylurethan, m. 87–8°. There is obtained also some *o*-phenylcyclohexanol (III), b₁ 138–40°, n_D^{16} 1.5115, which appears to be a geometrical isomer of the III (m. 54.5°) prepd. in other ways; the 2 isomers, however, form the same phthalate and the same phenylurethan. KOH reconverts II into I. If the reaction mixt. is freed from Et_2O and then decompd. with H_2O there result considerable amts. of diphenyl, III and 2-cyclohexenol (IV), b₁ 164.6°, b₂ 65°, d_4^{26} 1.00, n_D^{26} 1.499. IV absorbs Br but attempts to study the double bond by reduction and oxidation were unavailing. REYNOLD C. FUSON

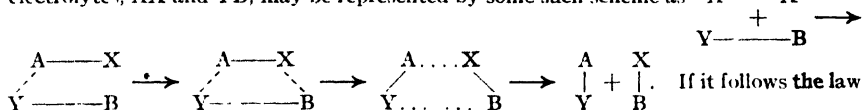

Inactivation of the catalysts in the transformations of carbon compounds. N. D. ZELINSKII (WITH MRS. M. B. TUROVA-POLLAK). *Ber.* 59B, 156–62 (1926), cf. C. A. 19, 1392. — According to the views developed in the earlier paper, the catalyst, depending on its own nature and the nature of the catalyzed mols., changes the form of the latter. If an org. substance is being catalyzed, it in part undergoes a deep-seated decomposition of the mols. in contact with the catalyst, there are always some whose temp. rises above the mean temp. and these decomp. and gradually cover the active surface of the catalyst with a thin film of C, thereby progressively decreasing the activity of the catalyst, removal of this film should then restore the activity of the catalyst if the structure of the extreme outside layer of the contact mass has not been materially altered by the deposition of the C. Willstätter and others have found that Pt black inactivated by use for catalytic hydrogenation can be reactivated by periodic treatment with O; this they believe to be due to the formation of a peroxide which, and not the Pt itself, acts as the catalyst through the formation of intermediate compds. with H. This reactivation, however, may also be explained as resulting from the action of the O on the film of C formed on the catalyst during the preceding reaction. Preliminary expts. showed that pure birch charcoal (with an activity of 12.5% with respect to petroleum ether) is oxidized even at room temp. in a current of O (yielding 0.004% CO_2 per hr.) and the oxidation is, as was to be expected, much more energetic in the presence of Pt or Pd black. The amt. of CO_2 formed from various Pt and Pd catalysts whose activity had been weakened or completely annulled by previous use for hydrogenation or dehydrogenation was then detd. at gradually increasing temps. The results obtained with 9 such catalysts (Pd-asbestos, Pt- and Pd charcoal and active birch charcoal) are reported. The curves all have the same general form, the formation of CO_2 begins at room temp., rises steeply to a max. at 150–250° and then falls as steeply as the temp. is further increased to around 300°; after such treatment the original activity of the catalyst is completely restored. C. A. R.

Reduction of *o*-phenyleneaceticpropionic acid and different aromatic amines with hydrogen by the use of platinum oxide-platinum black as catalyst. XII. G. S. HIERS AND ROGER ADAMS. *Ber.* 59B, 162–70 (1926), cf. C. A. 20, 376, Helfer, C. A. 18, 270; Skita, C. A. 19, 824. The present work confirms the observation that the Pt oxide–Pt black catalyst (I) of A., when properly prepd. and used, often if not always is a better catalyst than colloidal Pt, even when employed under the hitherto most favorable conditions known. From 10 g. *o*-HO.CCH₂.C₆H₄.CH₂.CH₂.CO₂H in 150 cc. of 95% alc. re-

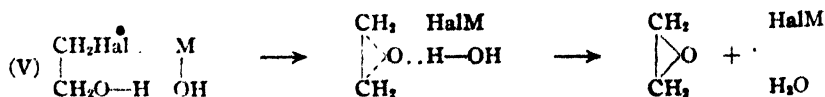

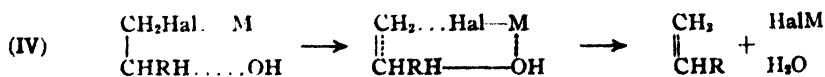

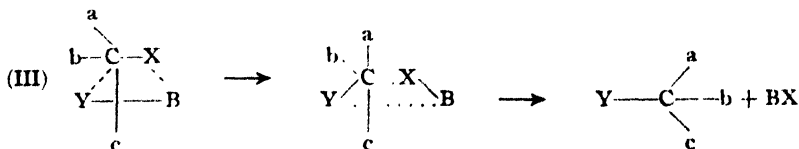

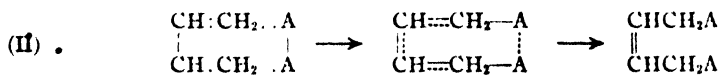

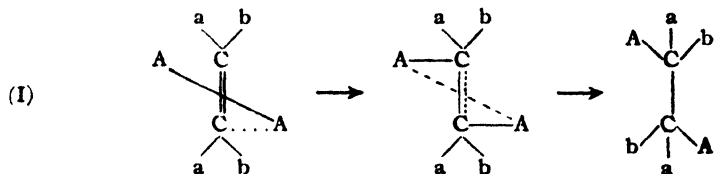

duced 51 min. with 1 g. I at 50° and 2-3 atm. is obtained quant. the hexahydro deriv., although not in a form as easily purified as that obtained by Helfer and by S.; the product is apparently a mixt. of stereoisomers, m. 73-7°, the m. p. rising only gradually on recrystn.; purification through the Na salt gave a product m. 78-92°. Comparative expts. on PhNH₂, PhNHMe, PhNMe₂ and PhCH₂NH₂ with S.'s colloidal Pt (II) and with I showed that a smaller amt. of I than of II is required to obtain the same degree of reduction; complete reduction can be effected with relatively small amts. of I, although in this case a long time is required; to obtain complete reduction with II, the concn. of the II must be high; increase in the concn. of I beyond a certain point apparently does not reduce the length of time required for reduction; increase in temp. increases the velocity of reduction with II more than with I. Alc. is a better solvent than AcOH with I; reduction (of PhNH₂.HCl) is more rapid in 95% than in abs. or in more dil. alc., but 75% alc. was used as it is a better solvent, as a whole, for all the amines which were studied. With I the velocity of reduction increases in the order PhNMe₂ → PhNH₂ → PhNHMe. The products are the same as those obtained by S. but in the reduction of PhNH₂ the relative yields of C₆H₁₁NH₂ and (C₆H₁₁)₂NH do not vary as widely with small variations in the exptl. conditions. C₆H₁₁NH₂, which b₇₄₄ 132-3°, forms with H₂O a const.-boiling mixt. b₇₄₈ 94-5°; the only satisfactory agent for removing the H₂O from this mixt. is Na. PhNMe₃Cl is reduced only very slowly; 4 mols. H₂ are taken up, with formation of Me₃NHCl and C₆H₁₂. Traces of Fe³⁺ salts act as a catalyst poison in the reduction of amines, and an exhausted catalyst cannot be reactivated with O.

C. A. R.

Stereochemical studies. XI. The reaction distances of anions. BROR HOLMBERG. *Ber.* 59B, 125-34(1926); cf. C. A. 20, 372.—The reaction between 2 non-electrolytes, AX and YB, may be represented by some such scheme as $A \cdots X + Y \cdots B \longrightarrow$

for a bimol. reaction, it passes through the intermediate stages with immeasurable velocity and no isolation or other direct proof of an intermediate product is possible, and the 3 intermediate formulas represent merely arbitrarily chosen moments of a continuous process. The novel point in them is that to the mols. AX and BY are ascribed at least at the instant of reaction, different intramol. distances, designated *reaction distances* (R.D.) $A \longleftrightarrow X$ and $B \longleftrightarrow Y$. When, e. g., a compd. A₂ undergoes *trans*

the Na salt of the above acid with KOH at 310°, was prepd. by converting *o*-xylene through the 3-NO₂ deriv. into the *vic-o*-xylidine (whose Ac deriv., m. 135°), thence into the xylenol and 2,3,4-Me₃(HO)C₆H₂CHO, m. 171-2°, and reducing the latter by the Clemmensen method; its *Ac* deriv., b. 239-41°; phenylurethan, m. 126.5-7.5°; benzeneazo deriv., yellow-red, m. 110-1°. The yield of I, b. 248-9°, has been increased to 85% by letting the mixt. of II, amalgamated Zn and HCl stand several hrs. at room temp. before heating; acetate, m. 59-60°; phenylurethan, m. 148-9°. C. A. R.

Ketonic fission of tertiary alcohols. V. GRIGNARD AND F. CHAMBRET. *Compt. rend.* 182, 299-302 (1926).—The discovery that certain tertiary alcs. decomp. on distn. to ketones (C. A. 17, 3157) led to a systematic study to det. whether the reaction is general. The present work deals with several series of satd. alcs. and α -, β - and γ -ethylenic alcs., the majority of the alcs. being new and described only recently by Chambret (*Diss. Lyon* 1925). On distn. the satd. alcs. and β - and γ -ethylene alcs. were very resistant, but on prolonged boiling traces of ketones were formed. The α -ethylenic alcs. on the contrary decompd. easily on distn., particularly *in vacuo*. Phenylmethyl- α -octenecarbinol gave PhCOMe, benzylmethyl- α -octenecarbinol gave *enanthydric-acetone*. The latter, prepd. in 70-5% yield by the method of G. and Dubien (C. A. 19, 1247), closely packed leaflets, m. 70-2°, changing in a few months to a *dimer*, m. 100-3°. As the temp. of distn. was increased, dehydration of the alcs. decreased and the ketonic decompn. increased, so that at 650-700° the latter was practically the only reaction, except for charring. With brick dust or pumice only dehydration occurred, but with glass wool excellent results were obtained, charring no longer being extensive and the max. yields of ketones being obtained at lower temps. (550-600°). With both glass wool and distn. *in vacuo* the yields were a max. at 400-500° and charring was eliminated. With glass wool either at ordinary pressure or *in vacuo*, the reaction is a general one. The following data give the alc., the ketone formed and its approx. % yield: MeCPr (OH)CH₂CH:CH₂ \rightarrow MeCPrCO (50 at atm. pressure, 60-5 at 500° and 160 mm.), MeC(CH₂Ph)(OH)CH₂CH:CH₂ \rightarrow Me(PhCH₂)CO (60 at atm. pressure, 90 at 400-50° and 30 mm.), MeCPh(OH)CH₂CH:CH₂ \rightarrow PhMeCO (80), MeCnBu(OH)CH₂CH:CHMe \rightarrow MeBuCO (30), MeC(CH₂Ph)(OH)CH₂CH:CHMe \rightarrow Me(PhCH₂)CO (60-5 at atm. pressure, 90 at 400° and 30 mm.), MeCPh(OH)CH₂CH:CHMe \rightarrow PhMeCO (80), γ -butenylmethylbutylcarbinol \rightarrow Me(CH₂:CHCH₂CH₂:CO (20-30), γ -butenylmethylbenzylcarbinol \rightarrow Me(CH₂:CHCH₂CH₂:CO (50-60), γ -butenylmethylphenylcarbinol \rightarrow PhMeCO (50), γ -pentenylmethylbutylcarbinol \rightarrow Me(MeCH:CHCH₂CH₂:CO (50), γ -pentenylmethylbenzylcarbinol \rightarrow Me(MeCH:CHCH₂CH₂:CO (50-60), γ -pentenylmethylphenylcarbinol \rightarrow PhMeCO (50-60), MeC(OH)Bu₂ \rightarrow MeBuCO (30), PhC(OH)Me₂ \rightarrow PhMeCO (80), PhC(OH)Me₂ \rightarrow PhMeCO (80), PhCH₂C(OH)Me₂ \rightarrow Me₂CO (60), EtCPr(OH)Bu \rightarrow unidentified mixt. Excellent yields were obtained *in vacuo* and the method should be of value in the *prepn.* of ketones when the corresponding alc. is more economical than the acid. It also offers a means of detg. the "affinity capacities" of the different radicals united to the tertiary C, the group with the least capacity forming the hydrocarbon on decompn. to the ketone. The results indicate that the capacities decrease in the order: Et > Me > γ -ethylenic > PhCH₂ or aliphatic radical (except Me) > α -ethylenic. The results did not, however, allow the α -ethylenic to be distinguished from the γ -ethylenic radical. The probable necessity of higher temps. and the catalytic process of Sabatier and Senderens render this method of doubtful value or utility in the *prepn.* of aldehydes from primary alcs. C. C. DAVIS.

Velocity of chlorination of toluene. F. BERGEL. *Ber.* 59B, 153 5 (1926). In connection with the revision of Cattermann's *Praxis des organischen Chemikers*, it became necessary to det. whether in the *prepn.* of PhCH₂Cl light really does not accelerate the chlorination of the side chain, as claimed by Book and Eggerth (C. A. 18, 668). A series of comparative expts. in the light and in the dark under the conditions given in the 19th edition of G.'s book showed that sunlight does quite materially accelerate the chlorination; Erdmann's statement, however, that PCl₅ catalyzes the chlorination of side chains in C₆H₅ derivs. (*Ann.* 272, 150) does not hold, at least insofar as the *prepn.* of PhCH₂Cl is concerned. C. A. R.

Nitration of aromatic compounds with bismuth nitrate. L. SPIEGEL AND HERBERT HAYMANN. *Ber.* 59B, 202-4 (1926).—Bi(NO₃)₃ (I) exerts a nitrating action on certain aromatic compds. at relatively low temps. without the aid of an acid (such as H₂SO₄) to set free the HNO₃. With C₆H₆ and PhMe no NO₂ derivs. can be isolated even after long boiling with I, although the formation of MeC₆H₄NO₂ can be detected by the odor. *p*- and *m*-xylene after several hrs. in sealed tubes give the corresponding toluylic acid. C₁₀H₈ gives a little α -C₁₀H₇NO₂; anthracene yields the quinone. PhOH reacts at room

temp., also in AcOH; with $1/3$ mol. I are obtained *o*- and *p*- $O_2NC_6H_4OH$ in the ratio 2:1.1; with more I the yield of mono- NO_2 derivs. decreases and tarry mixts in which picric acid could be detected are formed; PhOMe gives practical amts. of the *o*- and *p*- NO_2 derivs. only with 1 mol. I on the H_2O bath; β - $C_{10}H_7OH$ under widely varying conditions forms only smearable products, but its Et ether with I in AcOH at room temp. yields α , β - $C_{10}H_6(NO_2)_2OEt$ (II); *o*- $HOC_6H_4CO_2Me$ gives the 3- NO_2 deriv. Benzoquinone gives a small amt. of nitranilic acid, and anthraquinone at 200° yields the *o*- NO_2 deriv. PhNO₂ and $MeC_6H_4NO_2$ yield no more highly nitrated products, II gives the 1,8 di- NO_2 compd. $BzOH$, *o*- $C_6H_4(CO_2H)_2$, $PhSO_3H$ and $C_{10}H_7SO_3H$ and their esters do not react. ($C_6H_4(CO_2Et)_2$ is sapond. on long boiling with I). PhNH₂ does not react, PhNHAc only after the addn. of Ac_2O (which, however, liberates HNO_3 from I) with formation of the *o*- and *p*- NO_2 derivs.; *p*- $MeC_6H_4NH_2$ with $2/3$ mol. I forms an addn. product without being nitrated. *Addendum*.—Decompn. of $Bi(NO_3)_3$ on heating. S. and H.'s results agree best with Ivon's (*Compt. rend.* 84, 1161(1877)) as to the temp. (140°) at which the basic salt obtained by heating the crystd. I attains the const. compn. $BiONO_3 \cdot 0.5H_2O$ but they also find that this salt can be obtained by long heating at 120° if the HNO_3 liberated is removed as fast as it is set free by means of a current of dry air.

C. A. R.

Some *p*-phenoxyureas and thioureas derived from *p*-phenoxyaniline. The effect of the phenoxy group on the taste. N. A. LANGE and W. R. REED. *J. Am. Chem. Soc.* 48, 1069-74(1926).—Detailed directions are given for the prepn of *p*- $O_2NC_6H_4$, OPh ; the *p*- NH_2 deriv. (I) b.p. 315–20°, m. 82° (all m. ps. are cor.), the HCl salt (II) m. 222°. II and KCNO give 86% of *p*-phenoxyphenylurea, m. 178° and is tasteless. I and PhNCO give 70% of *p*-phenoxycarbanilide, m. 201° and is tasteless. The *p'*- Me deriv. m. 204°. α -*p*-Phenoxyphenyl- β - α -naphthylurea m. 216°; 86% yield. II and KCNS give 84% of *p*-phenoxyphenylthiourea, m. 181° and has a very slightly bitter taste. *p*-Phenoxythiocarbanilide, m. 140° and has a very slightly bitter taste, yield, 90%. I and CS_2 in EtOH contg. a little NaOH give 36% of *p,p'*-diphenoxythiocarbanilide, m. 172°, and is tasteless. These results indicate the effect of the PhO group in decreasing both the sweet and the bitter taste.

C. J. WEST

Nitration of benzylamine derivatives. R. ROBINSON. *Chemistry & Industry* 45, 9-10(1926).—The nitration of $PhCH_2NH_2$ and $(PhCH_2)_2NH$ at 90–100° yields appreciable quantities of *p*- NO_2 compds. Nitration of $(PhCH_2)_2NMe$ yields *m,m'*-dinitro derivs., together with the *o*- and *p*-derivs. Nitration of $PhCH_2NMe_2$ yields chiefly the *p*-deriv. About 50% of the *m*-deriv. is formed in the nitration of benzylpiperidine. Benzylphthalimide is nitrated largely in the *p*-position. Nitration of benzyltrimethyl ammonium nitrate yields 75% of the theory of *m*-deriv.

T. S. CARSWELL

New method for the thioxyanation of organic compounds. H. P. KAUFMANN and W. OEHRRING. *Ber.* 59B, 187-94(1926).—If $PhNH_2$, e. g., in a strongly acid soln contg. NaSCN is treated in the cold with Br, the reaction $2NaSCN + Br_2 = 2NaBr + (SCN)_2$, being ionic, proceeds so rapidly that the reaction $PhNH_2 + Br_2 = BrC_6H_4NH_2 + HBr$ is negligible if an excess of NaSCN is used. The hydrolysis $3(SCN)_2 + 4H_2O = 5HSCN + H_2SO_4 + HCN$ is greatly retarded in the presence of the acid, and the same is true of the polymerization, so that under these conditions the reaction $PhNH_2 + (SCN)_2 = p\text{-}NCSC_6H_4NH_2$ (I) + HSCN takes place. Numerous other substances have been successfully thioxyanated in this way. I, m. 57–8°, was obtained in 87% yield from 4.6 g. $PhNH_2$ in 12 cc. of 96% AcOH and 25 g. NaSCN in 130 cc. AcOH treated with 5.09 cc. Br in 35 cc. AcOH; the AcOH mother liquors yielded 15% of 2,4-dithiocyanooaniline, m. 198°. 1- $C_{10}H_7NH_2$ gives no mono NCS deriv., 2,4-dithiocyanoo-1-naphthylamine, m. 204°, is obtained in 7 g. yield from 12 g. $C_{10}H_7NH_2$, 17 g. NaSCN and 3.0 cc. Br in AcOH, while with 4.06 g. preformed $(SCN)_2$ (from $Pb(SCN)_2$ and Br) in Et_2O , 10 g. $C_{10}H_7NH_2$ yields 71% 4-thiocyano-1-naphthylamine, m. 146–7°, converted by standing in the air in alc. contg. a few drops of NaOH into [1,4- $C_{10}H_6(NH_2)_2S]_n$, m. 168°. 2- $C_{10}H_7NH_2$ (7.15 g.) with 16 g. NaSCN and 2.5 cc. Br yields almost quant. 1-thiocyano-2-naphthylamine (II), sinters 150–4°, turns yellow, resolifies and finally m. 261° (decompn.), converted into the amorphous 50% II is obtained (*p*- $NCSC_6H_4$)₂NH, m. 120°, is obtained in good yield from 0.2 g. $PhNH_2$, 2 g. NaSCN and the calcd. amt. of Br in 15% H_2SO_4 . 1- $C_{10}H_7OH$ (4.2 g.) with 9 g. NaSCN and cc. Br in AcOH gives 70% 1,4- $C_{10}H_6(OH)SCN$, m. 113°, while 1 g. of the naphthol with 8 g. KSCN and 0.6 cc. Br yields 60% of 2,4-dithiocyano-1-naphthol, faintly yellow, m. 118–9° (decompn.). 5,2-NCS(HO) $C_6H_4CO_2H$, m. 167°, is obtained in 0.2 g. yield from 1.38 g. *o*- $HOC_6H_4CO_2H$, 4 g. NaSCN and 1 cc. Br in HCO_2H ; the yield can undoubtedly be increased by changing the conditions. $(CH_3SCN)_2$, m. 90°, is obtained by

passing C_2H_4 and Cl separately (care being taken that the C_2H_4 is always in excess) into NaSCN in cold AcOH, or by using Br in 15% HCl instead of Cl. Styrene (1 g.) with 2 g. NaSCN and 0.5 cc. Br in AcOH yields 65% of $PhCH(SCN)CH_2SCN$, m. 101°; 2.8 g. anethole with 9 g. NaSCN and 1 cc. Br gives 75% of $p-MeOC_6H_4CH(SCN)CH_2SCN$, m. 87°, and from 1.2 g. antipyrine (III) and 2 g. NaSCN treated with Br in AcOH, the reaction mixt. then being dild. with an equal vol. of H_2O and made faintly alk. with 15% NaOH, is obtained 1.3 g. bis-[1-phenyl-2,3-dimethyl-5-pyrazolonyl] 4-disulfide, m. 256°, also obtained in 70% yield from 1.8 g. III and 5 g. NaSCN in AcOH treated with Cl until the mixt. gave no red color with $FeCl_3$ and then worked up as above C. A. R.

***p*-Nitrophenylhydrazine, its preparation and gravimetric utility.** HERBERT HENRY HODGSON AND HERBERT GREENSMITH BEARD. *J. Soc. Chem. Ind.* **45**, 56T (1926).—*p*-Nitrophenylhydrazine-HCl (I) is prepd. by adding $p-NO_2C_6H_4N_2Cl$ to neutral Na_2SO_3 soln., followed by recrystn. of the crude product from concd. HCl. Aldehydes and ketones are gravimetrically detd. by the following method: 2.5 g. of $m-OHC_6H_4CHO$ is dissolved in 25 cc. AcOH and 25 cc. H_2O , 5 cc. of the resulting soln. is added to 50 cc. H_2O and an excess of I is added. The mixt. is heated to 50°, cooled, filtered through a Gooch crucible and dried at 100°. Erratum. *Ibid* 56T.—Correction in the amt. of $NaNO_2$ taken for diazotization. T. S. CARSWELL

Symmetrical di(methylphenylmethyl)hydrazine and related compounds. W. A. SCHULZE AND H. L. LOCHE. *J. Am. Chem. Soc.* **48**, 1030-5 (1926).—Acetophenone ketazine is obtained almost quant. from 2 mols. PhAc and 1 mol. $N_2H_4 \cdot HCl$ at room temp. Catalytic reduction proceeds smoothly only with a fresh sample, yielding symdi(methylphenylmethyl)hydrazine, analyzed as the HCl salt, m. 188°; NO deriv., straw-colored oil, heavier than H_2O ; the oxalates could not be purified. 1,2-Bismethylphenyl methyl-4-phenylsemicarbazide, m. 108°; the 4-phenylurazole resulting by heating to 155°, m. 105.5°. Oxidation of the hydrazine with perhydrol gave 70-90% of a compd., $C_{18}H_{18}N_2$, m. 74°, which gives a good yield of $(MeCHPh)_2$ on distg. *in vacuo*. The hydrazine is reformed by reduction with Al-Hg in 95% EtOH. Methylphenylmethylhydrazine oxalate, m. 172° (decompn.); di-Bz deriv., m. 193°. C. J. WEST

3,4- and 2,5-Dimethoxyphenylhydrazine. WM. H. PERKIN, JR. AND LEON RUBENSTEIN. *J. Chem. Soc.* **1926**, 357-62.—3,4-(MeO) $_2C_6H_3NH_2 \cdot HCl$ (20 g.) in 90 cc. glacial AcOH is diazotized with $MeNO_2$, the diazo salt pptd. with Et_2O , dissolved in ice-cold H_2O and added to stirred $(NH_4)_2SO_3$ soln. at 0°, giving 14 g. NH_4 3,4-dimethoxydiazobenzenesulfonate, red; reduction with Zn dust and AcOH gives 9.5 g. NH_4 3,4-dimethoxyphenylhydrazinosulfonate, grayish white with a metallic luster; 12 g. of this salt, boiled with EtOH-HCl (30 cc. of 15%) for 0.5 hr., gives 4.5 g. 3,4-dimethoxyphenylhydrazine-HCl (I), gray, m. 162° (decompn.); it readily decomp. in the air and gradually loses HCl under reduced pressure; the free base, m. 81°, rapidly decomp. in contact with air. Cyclohexanone and I in EtOH contg. AcONa give 6,7-dimethoxytetrahydrocarbazole, pale yellow, m. 98°. I and $AcCO_2Et$ in EtOH contg. AcONa give Et 5,6-dimethoxyindole-2-carboxylate, yellow, m. 172°. NH_4 2,5-dimethoxydiazobenzenesulfonate, brick-red; the phenylhydrazine deriv., by reduction, is gray and with HCl gives 2,5-dimethoxyphenylhydrazine-HCl (II), darkens above 250°; it rapidly decomp. in the air. The free base m. 84°. II condenses with ketones with such difficulty that the work was discontinued. α -Ketoglutaric acid and $o-MeOC_6H_4NHNH_2 \cdot HCl$ in EtOH contg. AcONa give the yellow methoxyphenylhydrazone, m. 168° (decompn.), which, boiled with EtOH-HCl for 0.5 hr., gives Et 2-carbomethoxy-7-methoxyindole-3-acetate, gray, b₁₁ 245-55°, m. 106°, the free acid, brown, m. 253° (decompn.). Similarly was prepd. 2-carboxy-5-methoxyindole-3-acetic acid, pale yellow, m. 265°, the intermediate products not crystg. C. J. WEST

Amino ethers of the ephedrine group. Ethers of α -phenyl- γ -aminopropyl alcohols. W. DULIÉRE. *Bull. soc. chim.* **39**, 285-92 (1926); cf. *C. A.* **18**, 815, 2494.—The ethers are prepd. by heating the appropriate chloro ethers with the amine in a closed tube for several days at temps. not exceeding 125°. A single distn. of the liquid portion of the reaction product is usually sufficient to give the pure amine. The yields are very good. The following compds. are described: Me α -phenyl- γ -dimethylaminopropyl ether, b₁₂ 170° (HCl salt, sirupy and hygroscopic); Me α -phenyl- γ -diethylaminopropyl ether, b₁₂ 180° (reduced pressure), d₂₀ 0.942; Et α -phenyl- γ -diethylaminopropyl ether, b₁₂ 155° (reduced pressure), d₂₀ 0.921 (HCl salt, m. 74°); Pr α -phenyl- γ -diethylaminopropyl ether (HCl salt, m. 94°); iso-Bu α -phenyl- γ -diethylaminopropyl ether, d₂₀ 0.927 (HCl salt, m. 125°); iso-Am α -phenyl- γ -dimethylaminopropyl ether, d₂₀ 1.011 (HCl salt, hygroscopic). REYNOLD C. FUSON

Reaction between organomagnesium halides and the aryl esters of boric, carbonic, silicic and phosphoric acids. HENRY GILMAN AND C. C. VERNON. *J. Am. Chem. Soc.* **48**, 1063-6 (1926).— $B(OMe)_3$, contrary to the expts. of others, has no methylating action towards $PhMgBr$; all aryl esters of O acids thus far studied show no arylating action with Grignard reagents, the O-aryl group being replaced. From 0.25 mol. $B(OMe)_3$ and $PhMgBr$, 86% of $PhB(OH)_2$ is obtained; with 0.64 mol. $B(OMe)_3$, 58% $PhB(OH)_2$ and 30% C_6H_6 . $B(OPh)_3$ and 3 equivs. of $BuMgBr$ give 80% of $PhOH$ and a small amt. of a yellow compd., probably Bu boride. $PrMgBr$ gives 56% $PhOH$ and 7% Pr boride. 0.1 mol. $B(OPh)_3$ and 4 equivs. of $PhMgBr$ in Et_2O give 40% $PhOH$, 16.5% $PhB(OH)_2$ and 1.3% Ph_2 . Ph_2CO_2 (0.1 mol.) and 0.25 mol. $PhMgBr$ give 69% Ph_2COH , 6-21% $BzOPh$ and 45-61% $PhOH$. Ph_2CO and $EtMgBr$ give no $PhEt$. Equiv. amts. of $(p-MeC_6H_4O)Si$ and $PhMgBr$ give 17.5% unchanged ester, 46.5% $p-MeC_6H_4OH$ and a complex Si compd. $PhCH_2MgCl$ gives 30% $p-MeC_6H_4OH$, $(PhO)_3PO$ and $PhMgBr$ give 17% of Ph_3PO and 49% $PhOH$. $PrMgBr$ at 95% gives 49% $PhOH$ and a compd. b. 280-2° and m. 36°, which may be Pr_2PO . $(p-MeC_6H_4O)PO$ (0.1 mol.) and 0.4 mol. $PhCH_2MgCl$ at 95° give 28% $p-MeC_6H_4OH$ and 15.5% of a compd., m. 148°; $PhMgBr$ gives 50% Ph_3PO and 51% $PhOH$. Ph_3PO is not reduced to Ph_3P by the Grignard reagent. $(PhO)_3P$ and $PhMgBr$ give 60% Ph_3P and 68% $PhOH$. C. J. WEST

Reactions of mercury diphenyl with some acyl halides. H. O. CALAPRY. *J. Am. Chem. Soc.* **48**, 1009-2 (1926).— $ClCO_2Et$, $AcCl$ and $BzCl$ all react with $HgPh_2$ to give $PhHgCl$; $AcCl$ gives $PhAc$ while $BzCl$ gives $PhCO$ and possibly both give $PhClCO_2Et$ does not give $BzOEt$ in large enough quantities to be identified. Thus $HgPh_2$ is probably not an intermediate product in the formation of $BzOEt$ from $PhBr$, $ClCO_2Et$ and $Na-Hg$ but a by-product of that reaction. $AcCl$ is the most reactive of the 3 halides towards $HgPh_2$. $PhMgCl$ is sol. to the extent of 1 g. per 100 cc. 10% $NaOH$. An improved method for the prepn of $HgPh_2$ is given. C. J. WEST

Mercurated hydroxyazobenzenes. F. C. WHITMORE, E. R. HANSON AND G. J. LEUCK. *J. Am. Chem. Soc.* **48**, 1013-6 (1926).—Diazotized $p-H_2NC_6H_4SO_3H$ added to $o-HOC_6H_4HgCl$ in alk. soln. gives Na 3-chloromercuri-1-hydroxyazobenzene-4'-sulfonate, orange-yellow; attempts to prep the free acid failed because of the ease with which the C-Hg linkage was split. Similar Na salts were obtained from metanilic and naphthionic acids, yellow and orange, resp., and the free acid from o -, m - and $p-H_2NC_6H_4CO_2H$. $o-HO_2SC_6H_4N_2Cl$ and 4,2,6-Me(AcOH) $_2C_6H_2OH$ give the yellow Na anhydro 3-hydroxymercuri-5-methylazobenzene-4'-sulfonate; attempts to prep the free acid or the Cl deriv. failed. $o-HO_2CC_6H_4N_2Cl$ gives the deep red anhydro 2-hydroxy 3-hydroxymercuri-5-methylazobenzene-2'-carboxylic acid; the 4'-carboxylic acid is very similar. All these compds. react with hot $NHCl$ and with hot aq. NaI with complete splitting of the C-Hg linkage. No difference in the stability of the linkage in the different compds. was detected. C. J. WEST

Mercuration of aromatic sulfides. GEORG SACHS AND MINNA OTT. *Ber.* **59B**, 171-5 (1926).— Ph_2S (10 g.) and 20 g. $Hg(OAc)_2$ boiled with 50 g. $AmOAc$ until the mixt. no longer gave a black color with $(NH_4)_2S$ (5 hrs.) yielded 5.5 g. of a substance, m. 120-45°, with 57-8% Hg and 4 g. p -phenylmercaptophenylmercuric acetate (I), $PhSC_6H_4Hg(OAc)_2$, m. 148°, 0.5 g. of which with 65% HNO_3 on the H_2O bath and then with $K_2Cr_2O_7$, H_2SO_4 gave 0.02 g. of a $PhSO_3C_6H_4NO_2$, m. 131.5-4.5° (mixed m. p. with o - $PhSO_3C_6H_4NO_2$ (m. 147°) 128-30°; with the p compd. (m. 143°) 140°). With $CaCl_2$ in $MeOH$, I gives quant. the chloride, $PhSC_6H_4HgCl$, m. 181°, 0.4 g. of which in hot alc. with NH_3 yields 0.19 g. of the compd. $(PhSC_6H_4Hg)_2NH_2Cl$, m. 164-7° (slight decompn.). From 1.1 g. $Hg(OAc)_2$ heated in aq. alc. $AcOH$ with 0.5 g. $PhSAc$ until the soln. began to become turbid was obtained 0.8 g. $PhSHgCl$, while 1.5 g. $Hg(OAc)_2$ boiled in a little H_2O with 1 g. $PhSAc$ gave 1.4 g. $(PhS)_2Hg$. C. A. R.

3,4-Diaminophenylarsonic acid and some of its derivatives. W. LEE LEWIS AND H. E. BENT. *J. Am. Chem. Soc.* **48**, 949-57 (1926). At 100-40° and 10 mm. pressure, over P_2O_5 , the compds. $H_2NC_6H_4AsO_3H_2$, $HO-CC_6H_4CONHC_6H_4(NH_2)AsO_3H_2$, and $CH_2(OCNH)_2C_6H_4AsO_3H_2$ lose H_2O ; the Mg salts of these compds. do not lose H_2O under the same conditions, showing that the loss takes place from the arsenic group. 4-Propionylaminophenylarsonic acid, does not m. at 260° (32% yield). The following derivs. of $H_2NC_6H_4AsO_3H_2$ were prepd. by a modified Schotten-Baumann reaction: 4-Valeryl, 59% yield; 4-phenylacetyl, 81%; 3-amino-4-acetylamino, m. 265-7°, 74%; 3-amino-4-propionyl, m. 230-5°, 40%; 3,4-divaleryl, 44%; 3,4-dichloroacetyl, 49%; 3,4-diphenylacetyl, 62%; 3,4-dibenzoyl, 53%; 3,4-diphenyl, 16.5%; 4-carbopropoxy, 81%; 4-carbobutyloxy, 43%; 3,4-dicarbethoxy, m. 192-2.5°, 23%; 3,4-dicarbopropoxy, 81%; 3,4-dicarbobutyloxy, 57%; 3,4-dicarbopropoxy, decomp. 185-7°, 13.6%. Aminoarsanilic

acid (I), and $\text{ClCH}_2\text{CONH}_2$ in NaOH give 62% of *N*-[phenyl-1-amino-4-arsonic acid]-glycine amide, light gray powder, darkens 215° , m. $234-41^\circ$ (decompn.); using 25% more alkali or recrystn. of the amide in excess of alkali gives 1,2-dihydro-3-amino-6-arsono-quinoxaline (II), m. 226° ; NH_4 salt, decomp. 200° . I and $(\text{COCl})_2$ give 32% of the 1,2-dihydro deriv. Bz deriv. of II, m. 234° ; hydroxyethyl deriv., in 34% yield from II and $(\text{C}_2\text{H}_5)_2\text{O}$. I and $\text{BrCH}(\text{CONH}_2)_2$ give the 1,2-dihydro-2-formamide-3-amino deriv. in 17.2% yield. Aminotryparsamide and $\text{HCH}(\text{OH})\text{OSONa}$ give a ppt. during the 1st half hour which appears to be the arseno compd. with but 1 NH_2 group reacting; after 15 hrs., there results 75% of the arseno deriv. of sulfoxylated aminotryparsamide, light yellow powder, does not change up to 260° . *N*-[4-Arsenophenyl]-aminomalonomide, 57% yield. I and $\text{CH}_3(\text{CO}_2\text{Et})_2$ in MeOH give 26% of malonylaminoarsanilic acid, light red, which loses H_2O at 139° . 4-Phthalylamino-3-aminophenylarsonic acid, in 15% yield from I and $\text{C}_6\text{H}_4(\text{CO}_2)_2$; it seems to lose vol. up to $203-7^\circ$, then increase in vol. at $240-5^\circ$ with no further change to 260° . 1,2-Di-[*N,N*-dimethylamino]-4-arsobenzenic, light pink, by refluxing I in MeOH-HCl.

C. J. WEST

10-Chloro-5,10-dihydrophenarsazine and its derivatives. I. The synthesis, preparation and some properties of 10-chloro-5,10-dihydrophenarsazine. HAROLD BURTON AND C. S. GIBSON. *J. Chem. Soc.* 1926, 450-64.—The constitution ascribed to 10-chloro-5,10-dihydrophenarsazine (I) has been proved correct by the following synthesis: $o\text{-H}_2\text{NC}_6\text{H}_4\text{AsO}(\text{OH})_2$ (36 g.), diazotized and treated with CuBr at $30-40^\circ$, gives 27 g. of *o*-bromophenylarsonic acid, m. 201° (decompn.), which is reduced by SO_2 in EtOH-HCl contg. a trace of I, giving 92.5% of *o*-bromophenylarsenious oxide, m. $234-8^\circ$; 27.2 g. of this, coupled with the diazo soln. from 13.8 g. $o\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$, gives 19.6 g. of 2-bromo-6'-nitrodiphenylarsonic acid, pale yellow, m. $254-5^\circ$ (decompn.), 11.5 g. of which is reduced by $\text{Fe}(\text{OH})_2$ in dil. NaOH, giving 9.8 g. of the amino deriv. (II), m. $213-4^\circ$. II (10.8 g.), K_2CO_3 and a trace of Cu powder in AmOH, boiled 12 hrs., and then reduced with SO_2 , give 8.6 g. I. II and Me_2SO_4 at room temp. give the 6'-methylamino deriv. (III), m. $193-4^\circ$ (decompn.), while after heating 3 hrs. on the H_2O bath, there results the 6'-dimethylamino deriv., m. $220-1^\circ$. An attempt to prep. the *N*-Me deriv. of I from III failed, only I being isolated from the reaction product. Likewise the action of AsCl_3 upon Ph_2NMe in $\text{C}_6\text{H}_4\text{Cl}_2$ or by heating together at 200° for 3 hrs. gave only I. I is obtained almost quant. by heating 17 g. Ph_2NH , 20 g. AsCl_3 and 40 cc. $\text{C}_6\text{H}_4\text{Cl}_2$ for 5 hrs. and crystg. from CCl_4 . When AsCl_3 and Ph_2NH are mixed in C_6H_6 , there ppts. the compd. $\text{Ph}_2\text{NH}\cdot\text{HCl}\cdot\text{AsCl}_3$; in the air the crystals become opaque and consist mainly of $\text{Ph}_2\text{NH}\cdot\text{HCl}$. AsCl_3 , Ph_2NH and $s\text{-C}_6\text{H}_4\text{Cl}_2$ developed no pressure after standing 16 months; the residue after making alk. and distg. with steam when treated in hot AcOH with HCl , gave I; the sol. intermediate product may be $\text{Ph}_2\text{NAsCl}_2$. $\text{H}_2\text{NC}_6\text{H}_4\text{NacPh}$ (22.6 g.), diazotized and treated with Na_2HAsO_3 , give 16.5 g. *p*-(phenylacetyl amino)phenylarsonic acid (*N*-acetyldiphenylamine-*p*-arsonic acid (IV), crystg. with 1.5 H_2O , m. 126° (decompn.); boiled with EtOH-HCl 1 hr., it yield *p*-phenylaminophenylarsonic acid, m. 265° (decompn.). When IV is reduced with SO_2 in EtOH-HCl, there is formed *p*-(phenylacetyl amino)phenylarsenious chloride, m. 111° . Boiling PhNH_2 and AsCl_3 for 72 hrs. give Ph_2NH and 39% of an insol. residue, converted into I by $\text{HCl}\cdot\text{Me}_2\text{CO}$. $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$, AsCl_3 and $o\text{-C}_6\text{H}_4\text{Cl}_2$ or $(\beta\text{-C}_{10}\text{H}_7)_2\text{NH}$, AsCl_3 and $s\text{-C}_6\text{H}_4\text{Cl}_2$ give 14-chloro-14,7-dihydrodibenzophenarsazine, yellow, m. 355° (decompn.). $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ does not react in this way but $(\alpha\text{-C}_{10}\text{H}_7)_2\text{NH}$, AsCl_3 and $\text{C}_2\text{H}_5\text{Cl}$ give 60% of 7-chloro-7, 14-dihydrodibenzophenarsazine, yellowish brown needles, m. $278-9^\circ$ (decompn.). A mixt. of 15 g. Ph_2NH , 2.9 g. As_2O_3 and 3.2 g. P_2O_5 , heated with stirring at $160-70^\circ$ for 1 hr., gives 10.7 g. recovered Ph_2NH and 5 g. 10,10-oxybis-5,10-dihydrophenarsazine (V), converted into I by HCl in Me_2CO . V (10.7 g.) and 3.2 g. AcCl in C_6H_6 give 3.5 g. of 10-chloro-5-acetyl-5,10-dihydrophenarsazine, m. $221-4^\circ$. BzCl and V, however, give a nearly theoretical yield of I and Bz_2O . I is characterized by the formation of mol compds. when crystd. from various solvents; the following were analyzed: I. AcOH; 2I. $\text{C}_2\text{H}_5\text{Cl}$; 2I. PhCl ; 2I. $\text{C}_6\text{H}_4\text{Cl}_2$; 2I. Me_2CO ; I. CCl_4 . The dark green soln. of I in AsCl_3 deposits on cooling the compd. I. AsCl_3 , scarlet, decomp. on exposure to the air or on washing with solvents. Ph_2NH (8.5 g.), 17.3 g. AsBr_3 and 20 cc. $o\text{-C}_6\text{H}_4\text{Cl}_2$ give 9.6 g. 10-bromo-5,10-dihydrophenarsazine, also obtained in 13.3 g. yield from 15 g. of the 10-Ac deriv. and HBr in AcOH. The 10-I deriv. was similarly prepd. V in BuOH deposits 10-butoxy-5,10-dihydrophenarsazine, pale yellow, m. $518-60^\circ$; if the soln. is satd. with dry H_2S , there results the 10,10-thio deriv., m. $256-64^\circ$ (decompn.). The 10-benzoyloxy deriv. m. $173-5^\circ$. II. The action of primary chloroarsines on diphenylamine and its homologs. *Ibid.* 464-70. Ph_2NH , PhAsCl_2 and $o\text{-C}_6\text{H}_4\text{Cl}_2$ give I almost quant. $\text{MeC}_6\text{H}_4\text{NHPH}$ (38.6 g.), AsCl_3 and $o\text{-C}_6\text{H}_4\text{Cl}_2$ give 51 g., 10-chloro-2-methyl-5,10-dihydrophenarsazine (VI), yellow m.

199–200° (decompn.); (*p*-MeC₆H₄)₂NH (32.7 g) gives 44.7 g. of the 2,8-di-Me deriv. (VII), orange, m. 261–2° (decompn.); the 5-Ac deriv. of the last 2 compds. m. 154–5° and 164–5° resp. and result by boiling them with Ac₂O. VI and chloramine-T give 2-methylphenarsazinic acid, decomp. above 300°; Na salt, hair-like needles; HCl salt, m. 209–11° (decompn.). VII gives the 2,8-dimethylphenarsazinic acid, decomp. without melting; Na salt, needles; HCl salt, m. 216° (decompn.), *N*-Ac deriv., m. 240° (decompn.). Ph₂NH and ClCH:CHAsCl₂ in *o*-C₆H₄Cl₂ give I quant; α -C₁₀H₁₁NHPh gives 7-chloro-7,12-dihydrobenzophenarsazine, m. 218.9°. C. J. WEST

Organic arsenic compounds. II. Mercurated arylarsonic acids. ERNST MASCH-MANN. *Ber.* 59B, 213–8(1926); cf. *C. A.* 19, 478.—The description by Raiziss, Kolmet and Gavron (*C. A.* 14, 408) of the chem. properties of their "phenylarsonic acid-mercuric acetates" and the work of M. show that these compds. contain no Hg attached to the C of the nucleus and that some of their phenylarsonic acids (3-amino-4-hydroxy, 3,5-diamino- and 3,5-dinitro-4-hydroxy, 4-carboxy) cannot be mercurated at all, the only ones of their acids from which really mercurated derivs. can be prepd. are 3-nitro-4-hydroxy- and 3,5-diacetyldiamino-4-hydroxyphenylarsonic acid (I); this is also true of 3-acetyl-amino-4-hydroxyphenylarsonic acid (II). 5-Hydroxymercuri deriv. of II, from II in cold NaOH allowed to stand 6–7 days in the dark with aq. Hg(OAc)₂; contg. a little AcOH (yield, almost quant), does not visibly change up to 300°, dissolves in Na₂CO₃, alkalis and NH₄OH and loses its Hg with (NH₄)₂S as HgS only on boiling, the time required for complete mercuration can be shortened to 1 hr. by heating the reaction mixt. on the H₂O bath but the product is more deeply colored than that obtained at room temp.; when it is shaken in H₂O suspension with 1-KI as long as the latter is decolorized and the resulting light yellow iodoarsonic acid (III) is cautiously hydrolyzed, there is obtained 3-amino-4-hydroxy-5-iodophenylarsonic (IV), identical with the product obtained by Berthelm in an other way (unpublished communication); IV and its Ac deriv. (III) are readily reduced at 40–50° by Na₂S₂O₄ to the corresponding arseno compds., yellow-gray powders sol. in Na₂CO₃ and in NaOH, but only that from IV is sol. in dil. HCl. 2-Chloromercuri deriv. of I, obtained in 70% yield from I in NaOH and Hg(OAc)₂ in H₂O contg. a little AcOH allowed to stand 30 days in the dark (the reaction cannot be hastened by heating, which produces deep-seated decompn.), the product being pptd. from cold dil. NaOH with dil. HCl, m. 234°, dissolves clear in Na₂CO₃, alkalis and NH₄OH, gives HgS with (NH₄)₂S only after boiling; with 1-KI the CHHg group is replaced by I and the resulting 2-iodoarsonic acid, C₁₀H₁₂O₆N₂IAS, is reduced by Na₂S₂O₄ to the arseno compd., sol. in alkalis. C. A. R.

Phenyltin compounds. R. F. CHAMBERS AND P. C. SCHERER. *J. Am. Chem. Soc.* 48, 1054–62(1926).—Ph₃Sn is obtained in 50% yields by the action of Na-Sn upon PhBr or in 90% yields from PhMgBr and ZnCl₂ (giving Ph₂Zn) and then adding SnCl₄ in PhMe. Ph₃Sn and I in CHCl₃ give Ph₂SnI, which gives 50% Ph₂SnBr (through the hydroxide). Na triphenyltin, pale yellow, amorphous powder, is oxidized by O₂ in liquid NH₃ to Ph₂SnOH, Ph₃Sn and Ph₂SnO, Ph₂SnONa being an intermediate product. Thermal decompn. of Ph₂SnOH gives Ph₃Sn, Ph₂SnO and H₂O. If cold C₆H₆ is used to ext. the reaction product, only Ph₂SnOH is found. In the reaction of Ph₂SnNa with aryl halides, direct substitution of the Ph₂Sn groups occurred in practically none of the cases studied. With PhHgI there results Ph₂Sn, NaI, Hg and phenylmercuramine, m. 123.5–4°, mol. wt. in freezing C₆H₆ normal. This was also obtained from KNH₂ and PhHgI in liquid NH₃. Ph₂SnNa and ClCH₂CO₂Na give the Na salt of triphenyltin acetic acid, m. 122–2.5°; mol. wt. in freezing C₆H₆ normal. Triphenyltin hydride is obtained from Ph₂SnNa and NH₄Br in liquid NH₃, it b_p 173–4° and becomes cloudy on exposure to the air, being oxidized to Ph₂Sn and H₂O, Na gives Ph₂SnNa which reacts with Ph₂SnCl₂ to give Ph₃Sn. Ph₂Sn is obtained from Ph₂SnBr₂ and Ph₂SnH₂ in liquid NH₃; the product is a yellow powder whose properties indicate a high state of polymerization. Free Ph₂Sn, obtained in the monomol form by the decompn. of Ph₂SnH₂, yellow, decomp. 205°; it is not readily oxidized by air in the solid state but Ph₂SnO is rapidly pptd. from its solns. Na and Ph₂Sn in liquid NH₃ give varying amts. of Ph₂SnNa and Ph₂SnNa₂, depending upon the conditions; the presence of the Ph₂SnNa₂ is probably due to the sec. reaction of Na upon Ph₂SnNa. C. J. WEST

Relative directive powers of groups of the forms RO and RR'N in aromatic substitution. I. JAMES ALLAN AND ROBERT ROBINSON. *J. Chem. Soc.* 1926, 376–83.—The directive power (calcd. from the % of the 2 isomers formed) in the nitration of ethers of *o*-MeOC₆H₄OH are as follows: MeO, 100; EtO, 135; PrO, 128; iso PrO, 150; C₆H₅O, 123; PhCH₂O, 113. The following f. p. curve for a mixt. of the 5-NO₂- and 4-nitroethoxyanisoles was detd.: 31.5% 5-NO₂ deriv., 83.7°; 37.8, 79.5°; 42.4, 75.4°;

50.9, 62.6°; 55.6, 60.1°. Nitration of *o*-MeOC₆H₄OEt gives 95% of a crude product contg. 42.5% of the 4-NO₂ and 57.5% of the 5-NO₂ deriv. Crystd. from MeOH (equil. ensured by keeping 5 hrs. at 16°) gave a product contg. 51.9% of the 4-NO₂ deriv. Further nitration of the mixt. gives the 4,5-dinitro-2-ethoxyanisole, pale yellow, m. 150°; reduction with Zn and dil. EtOH-HCl, addn. of AcONa and phenanthraquinone in aq. NaHSO₃ gives 3-methoxy-2-ethoxyphenanthraquinone, yellow, m. 231°, gives a deep magenta soln. in H₂SO₄ and fluoresces violet in C₆H₆. The action of H₂S in dil. EtOH-NH₄OH gives 6'-nitro-3'-(or 4')-methoxy-4'-(or 3')-ethoxyphenyl-4,5-thiotriazocatechol *Me Et ether*, yellow, m. 175°. 4-Nitro-2-propoxyanisole (I), m. 106° (70% yield from PrI, 5-nitroguaiacol and KOH in EtOH); 5-nitro deriv. (II), m. 72°; 65% yield. A mixt. contg. 31.5% I, m. 55.5°; 34.2, 59.9°; 36.7, 63.5°; 41, 69.6°; 44.2, 73.4°; 50.5, 79.3°; 53.6, 82.4°; 57.0, 84.6°. Nitration of *o*-MeOC₆H₄OPr below 9° gives 96% of a mixt. of 13.9% I and 56.1% II. 4,5-Dinitro-2-propoxyanisole, m. 143°. 4-Nitro-2-isopropoxyanisole (III), pale yellow, m. 83°; 5-nitro deriv. (IV), yellow, m. 53°; the yields are 30 and 15% resp. A mixt. contg. 24.6% IV, m. 69.7°; 30.4, 66.7°; 35, 63.7°; 39.5, 60.2°; 48.1, 53.8°. Nitration of 2-isopropoxyanisole, (b. 210-5°, 90% yield) gives 92% of a product contg. 40% III and 60% IV. The 4,5-dinitro deriv., m. 129°. 4-Nitro-2-butoxyanisole (V), m. 74°; 5-nitro deriv. (VI), pale yellow, m. 56°; mixts. contg. 25.5% V, m. 39.8°; 28.3, 37.5°; 33.2, 32.6°; 36.5, 30.4°; 39.6, 33.2°; 42.7, 35.2°; 45.1, 35.7°; 46.9, 35.5°; 50.7, 39.6°; 52.2, 41.8°; 53.8, 44.1°; a compd. contg. 44% V, m. 35.5°; the eutectic on the side of V is near 35°, on the side of VI near 30°. 2-Butoxyanisole, b. 236-9° (quant. yield), on nitration below 12°, gives a product contg. 44.8% V. The 4,5-dinitro deriv., faintly yellow, m. 97°. 4-Nitro-2-benzyloxyanisole, (VII), m. 93°. 98° (75% yield); 5-nitro deriv. (VIII), m. 82°, 55% yields; mixts. contg. 17.1% of VIII, m. 85°; 23.7, 80°; 33.6, 72.9°; 37.2, 69.2°; 41.3, 65.2°; 46, 57.2°. Nitration of *o*-MeOC₆H₄OCH₂Ph at 8° gives 98% of a product contg. 47% VII. II. The nitration of some 2-benzyloxyanisoles substituted in the benzyl group. A. E. OXFORD AND R. ROBINSON. *Ibid* 383-91.—Assuming the directive power of MeO to be 100, that of *m*- and *p*-O₂NC₆H₄CH₂ is 67, of *m*-MeOC₆H₄CH₂ 92. 2-*m*-Nitrobenzyloxyanisole, pale yellow, m. 47.5-8°; the 4-nitro-2-*m*-nitrobenzyloxyanisole (IX), m. 164.5-5°; the 5-nitro deriv. (X), m. 140.5-1.5°; a complete m. p. curve for IX and X is given. Nitration of the 2-*m*-nitro deriv. gives 98.4% of a product contg. 39.4% X. The 4-nitro (XI) and 5-nitro-2-*p*-nitrobenzyloxyanisole (XII), pale yellow, m. 167-8° and 163.5-4.5°, resp.; a complete m. p. curve for the 2 is given. Nitration of the 2-*p*-nitro deriv. at 100° (15 min.) gave a product contg. 42% XII; nitration at 11° gave 99% of a product contg. 39.5% XII. 2-*m*-Methoxybenzyloxyanisole, b_m 220°, m. 31.5°; 4-nitro deriv. (XIII), pale yellow, m. 116-7°; 5-nitro deriv. (XIV), pale yellow, m. 98.5-9.5°; a f. p. curve is given for 0-62% XIV. Nitration of the MeO deriv. gives 99% of a product contg. 52% XIII. 2-*p*-Methoxybenzyloxyanisole, m. 94-6°; satisfactory conditions for the nitration of this compd. could not be established. 4-Nitro deriv., pale yellow, m. 129-30°; 5-nitro deriv., pale yellowish brown, m. 109°; a f. p. curve is given up to 41% of the 4-nitro deriv. III. The nitration of some *p*-alkyloxyanisoles. R. ROBINSON AND J. C. SMITH. *Ibid* 392-401.—2,4-(O₂N(MeO))C₆H₃OH is obtained in 96% yield from 40 g. of the di-Me ether, 80 g. NaOH and 700 g. H₂O by heating 54 hrs.; it also results by hydrolysis with HBr. *Et p*-methoxyphenyl carbonate, b₁ 157°, in 93% yield from MeOC₆H₄OH and ClCO₂Et; complete soln. results after boiling with 10% NaOH for 5 min. The 3-nitro deriv., m. 66° (90% yield), gives on hydrolysis with NaHCO₃ 95% of 3,4-(O₂N(MeO))C₆H₃OH. 3-Nitro-4-ethoxyanisole, yellow, m. 39.5°; 2-nitro deriv., yellow, m. 37-9°; a complete f. p. curve of these 2 compds. is given. Nitration of *p*-MeOC₆H₄OEt gives 62.2% of the 3-NO₂ deriv. and 37.8% of the 2-NO₂ deriv.; hence the directive power of EtO in the quinol series is 163 (MeO, 100). 3-Nitro-4-propoxyanisole, b₁ 127°, m. 10.7°; the 2-nitro deriv., m. 32°; the f. p. curve is given from 48 to 100% of the 2-NO₂ deriv. Nitration of 4-PrOC₆H₄OMe gave 97% of a product contg. 64.35% of the 3-NO₂ deriv.; the directive power of PrO, is therefore, 180. 3-Nitro-1-*p*-nitrobenzyloxyanisole, yellow, m. 153° (98% yield); 2-nitro deriv., m. 123.5° (96% yield); the 2 form an eutectic at about 66% of the 2-NO₂ deriv. and at about 108°. 4-*p*-Nitrobenzyloxyanisole, yellow, m. 87.5°; nitration gives 98% of a mixt. contg. 72.4% of the 2-NO₂ deriv. IV. A discussion of the observations recorded in parts I, II and III. JAMES ALLAN, A. E. OXFORD, ROBERT ROBINSON AND J. C. SMITH. *Ibid* 401-11 V. The nitration of *p*-methoxydiphenyl ether. T. R. LEA AND ROBERT ROBINSON. *Ibid* 411-3. *o*-*m*-Methoxydiphenyl ether, b₁₀ 175°, in 19 g. yield from 15.5 g. *m*-MeOC₆H₄OH, 15.5 g. PhBr, KOH and Cu; *p*-deriv., b_m 186°, m. -10°. Nitration of the latter at 15° gives 3-nitro-4-methoxydiphenyl ether, pale yellow, m. 73-4°; hydrolysis with KOH gives 2-nitro-4-phenoxyphenol, yellow, m. 51-2° gives a bright red K salt. *o*

$\text{PhOC}_6\text{H}_4\text{OMe}$ probably gives the 3-nitro-6-methoxydiphenyl ether, pale yellow, m. $73-4^\circ$.

Molecular compounds of phenols. VII. The behavior of hydrogenated cresols and related compounds. G. WEISSENBERGER, F. SCHUSTER AND K. WOJNOFF. *Monatsh.* **46**, 1-8 (1925); cf. *C. A.* **20**, 1013.—Measurements are reported of the vapor pressure at 15° of solns. of various concns. of *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{OH}$ in PhMe , MeOH , CHCl_3 , and AcOEt , CS_2 and of *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{OH}$ in CHCl_3 and AcOEt . Surface tension and viscosity measurements for these mixts are also reported. Hydrogenation does not alter the valence relations of the cresols with CHCl_3 . While PhOH forms mol compds. with alcs., cyclohexanol does not; the same relations holds with the cresols; the cresols form mol. compds. with AcOEt but methylcyclohexanols do not. **VIII. Localization of the residual valence field of action.** G. WEISSENBERGER, F. SCHUSTER AND R. HENKE. *Ibid* 47-56.—Measurements of the vapor pressure of 1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$ solns. in MeOH , EtOH , Me_2CO and AcOEt indicate the formation of mol. compds. because the differences noted are much greater than with PhOH and the $\text{MeC}_6\text{H}_4\text{OH}$, these values indicate that the seat of the compd. formation is on the H of the HO group. The effect is less marked in the case of AcOEt . Methylcyclohexanol and MeOH do not form a mol. compd., nor do BzH and MeOH , indicating that the H in the CHO group, even when attached to a Ph residue, is not capable of forming mol. compds. with alcs. Cyclohexanone and AcOEt do not form a mol. compd. Viscosity and surface tension measurements for these systems are reported.

Organic molecular compounds. IX. The group $-\text{CCl}_3$. G. WEISSENBERGER, F. SCHUSTER AND R. HENKE. *Monatsh.* **46**, 57-60 (1925).—While results of the measurements of the vapor pressure of solns. of CHCl_3 in PhOH indicate compd. formation, $\text{ClCH}_2\text{CCl}_2$ and cyclohexanone do not form a compd. Viscosity and surface tension measurements are also reported. **X. The vapor pressure curves.** G. WEISSENBERGER AND F. SCHUSTER. *Ibid* 157-65.—Values are given for the const α and τ in van Laar's formula (*C. A.* **4**, 2062) for systems of *m*- $\text{MeC}_6\text{H}_4\text{OH}$ with 29 other components; comparison of the values from van Laar's curve with those from Raoult-van't Hoff for normal fluids shows that there is, in general, little difference. In all systems studied, the max. variation is near the mol. ratio 2:1. **XI. Dolezalek's theory.** *Ibid* 167-9.—From the course of the vapor pressure curves, W. and S. conclude that D.'s assumption (*C. A.* **3**, 603, **4**, 1123) does not hold and that we do not have at present a means of calcg. the amt. of mol. compd. formed from the course of the vapor pressure curve.

Bromophenols. XII. Bromo- and bromonitro ethers of pyrogallol. MORITZ KOHN AND SARA GRUN. *Monatsh.* **46**, 75-90 (1925), cf. *C. A.* **20**, 1394—1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$ (10 g.) and Br in CCl_4 give 11.5 g. 4,6-dibromopyrogallol tri-Me ether (I), b_{448} 294.6 $^\circ$, which gives with HNO_3 in AcOH the 5-nitro deriv., yellowish white, m. 110° ; $a:b:c = 1.81668:1.112290$; β 90.1047 $^\circ$, other crystallographic data are given. $\text{HBr} \cdot \text{AcOH}$ gives $\text{Br}_2\text{C}_6(\text{OMe})_3$, m. 168-71 $^\circ$. 5,1,2,3-(O_2N) $\text{C}_6\text{H}_2(\text{OMe})_2$ and $\text{HBr} \cdot \text{AcOH}$ give 5,1,2,3-(O_2N) $\text{C}_6\text{H}_2(\text{OH})_4$, crystg. with 0.5 H_2O , m. 194-46 $^\circ$; $a:b:c = 0.39386:1.018003$; β 96.555 $^\circ$; other data are given. 1,2,3- $\text{C}_6\text{H}_3(\text{OMe})_3$ and quinoline- H_2SO_4 , $\text{AcOH} \cdot \text{Br}$ mixt., well cooled, give the 4-Br deriv., b. 260-46 $^\circ$, further bromination gives I. HNO_3 gives the 5,6-dinitro deriv., yellowish needles, m. 134-5 $^\circ$. 2,6-(MeO) $_2$ - $\text{C}_6\text{H}_3\text{OH}$ and 4 mols. Br give 4,5,6-tribromo-1,3-pyrogallol di-Me ether, m. 134 $^\circ$; complete crystallographic data are given, 15 $^\circ$, alkalies give the K and Na salts. 2 mols. Br in CCl_4 and (MeO) $_2\text{C}_6\text{H}_3\text{OH}$ give the 4,5-di-Br deriv., m. 75.6 $^\circ$, Br deriv., m. 122.3 $^\circ$. Me_2SO_4 gives the tri-Me ether, b_{448} 308-13 $^\circ$, whose 6- NO_2 deriv., yellowish white, m. 84-6 $^\circ$. **XIII. On the exchange of halogen atoms and nitro groups in several nitro-halophenol ethers.** M. KOHN AND MELANIE HELLER. *Ibid* 91-100.—3,5- Br_2 - $\text{C}_6\text{H}_3\text{OMe}$, b. 257-61 $^\circ$; concd. HNO_3 gives the 2,4-dinitro deriv., m. 175 $^\circ$, sapon by concd. H_2SO_4 at 180-90 $^\circ$ to 2,4-dinitro 3,5-dibromophenol (II), pale yellow, m. 146.7 $^\circ$, whose Br deriv., m. 134.5 $^\circ$. Heating 1 mol II with 26 mols. PhNH_2 gives the 3,5-dianilino deriv., red, m. 177-8 $^\circ$. 2,4,6,3,5- $\text{Cl}_4(\text{O}_2\text{N})_2\text{C}_6\text{OMe}$, m. 94.5 $^\circ$, is sapon by concd. H_2SO_4 to 2,4,6-trichloro-3,5-dinitrophenol, m. 165.7 $^\circ$; K salt, Au yellow; pyridine salt, m. 139-48 $^\circ$. Boiling $\text{HBr} \cdot \text{AcOH}$ and 2,6,3,5- $\text{Br}_2(\text{O}_2\text{N})_2\text{C}_6(\text{OMe})_2$ give 2,6,3,5,6- $\text{Br}_4\text{C}_6(\text{OMe})_3$. Similarly 2,6,3,5- $\text{Cl}_2(\text{O}_2\text{N})_2\text{C}_6(\text{OMe})_2$ and $\text{HBr} \cdot \text{AcOH}$ give 2,6-dichloro 3,5-dibromohydroquinol di-Me ether, m. 170-2 $^\circ$, also obtained from 2,6,1,4- $\text{Cl}_2\text{C}_6\text{H}_2(\text{OMe})_2$ (b_{710} 258-9 $^\circ$, m. 34.5 $^\circ$). **XIV. New observations on halophenols.** M. KOHN AND ARTHUR ROSENFELD. *Ibid* 101-17.—*p*- $\text{ClC}_6\text{H}_4\text{OH}$ in aq. suspension and 2 mols. Br in KBr soln. give 2,6-dibromo-4-chlorophenol, m. 90 $^\circ$ (cor.); Me_2SO_4 gives the corresponding anisole (III), b_{448} 265-70 $^\circ$, m. 74 $^\circ$, whose 3-nitro deriv., m. 58 $^\circ$. With a larger amt. of concd. HNO_3 and H_2SO_4 , III gives 2,6-dibromo-4-chloro-3,5-dinitroanisole

m. 146° (cor.), sapond. by HBr AcOH to the corresponding *phenol*, m. 191° (cor.), K salt, yellow. With 9 mols. Br in KBr soln., *p*-ClC₆H₄OH in aq. suspension gives the keto bromide (*tribromochlorocyclohexadienone*), dark yellow, decomp. on heating, reduced by H₂SO₄ in EtOH to 2,6,4-Br₃ClC₆H₃OH; carefully warmed with concd. H₂SO₄, it gives 2,3,6-tribromo-4-chlorophenol, m. 104°. The corresponding *anisole*, m. 94° (cor.); its 5-nitro deriv., m. 120-1° (cor.), with HBr-AcOH gives 2,3,6-tribromo-4-chloro-5-nitrophenol, m. 141-2° (cor.); K salt, yellow; *Bz* deriv., m. 154° (cor.). 2,6-Diiodo-4-chlorophenol, rose-colored, m. 109° (cor.); the *anisole*, rose, m. 79° (cor.), for which crystallographic data are given (also for 2,4,6-I₃C₆H₂OMe). 3,5-Dibromo-2,4,6-triiodophenol, m. 199° (begins to decomp. 180°); the corresponding *anisole*, m. 202-5° (slight decompn.). 3,5-Dibromo-2,6-diiodoquinone, reddish yellow, m. 260° (decompn.). XV. Pseudophenols. *Ibid* 119-30.—Crystallographic data are given for 1,2,3,5-HO(Br)₂C₆H₂CH₂Br (IV); with N₂H₄·H₂O in Et₂O this yields *sym*-bisdi-bromo-*o*-hydroxybenzylhydrazine, m. 176°; with PhNH₂ in Et₂O, *asym*-dibromo-*o*-hydroxybenzylphenylhydrazine, m. 159°. IV and HNO₂(KNO₃ + AcOH) give a mixt. of 2-hydroxy-3-nitro-5-bromobenzyl acetate, golden, m. 134.5° (cor.), difficultly sol. in EtOH, and 2-hydroxy-3-bromo-5-nitrobenzyl acetate, m. 132° (K salt, yellow). HNO₂ and 2,3,5-HOBr₂C₆H₂CH₂NHPh give the compd. 2,3,5-HO(O₂N)BrC₆H₂CH₂N-(NO)Ph, yellow, m. 139-40° (cor.); K salt, bright red. *asym*-Dibromo-*p*-hydroxybenzylphenylhydrazine, m. 141°. XVI. A new tribromophenol, 3,4,5-tribromophenol, and a new tribromo-*o*-cresol, 1-methyl-2-hydroxy-4,5,6-tribromobenzene. M. KOHN and G. SPAR SOLTÉSZ. *Ibid* 245-51 (1926).—3,5-Br₂C₆H₃OH and Br in AcOH give 3,4,5-tribromophenol, m. 129°; complete crystallographic data are given. *Me ether*, b. 300-10°. m. 91-4°, whose 2,6-dinitro deriv., m. 127°. 4,5,6-Tribromo-*o*-cresol, m. 106°; *Me ether*, b. 320°, m. 105°.

C. J. WEST

Synthesis of hydroxydivarin. F. MAUTHNER. *J. prakt. Chem.* 112, 268-72 (1926).—3,4,5-Trimethoxyphenyl *Et* ketone, b₁₁ 177-8°, m. 51-2°, in 16.5 g. yield from 30 g. (MeO)₃C₆H₂COCH₂CO₂Et and 40 g. MeI in EtONa and heating the reaction product with 25% H₂SO₄ for 13 hrs; *p*-nitrophenylhydrazine, red, m. 182-3°. Reduction of 27.2 g. of the ketone with Zn-Hg and HCl gives 8 g. of 3,4,5-trimethoxy-1-propylbenzene, b₁₁ 143-4°, 3 g. of which, heated with HI (d. 1.96) for 5 hrs., give 1.7 g. of 3,4,5-trihydroxy-1-propylbenzene, m. 78°, identical with the hydroxydivarin isolated by Nakao from *Ramalina diracrata* (*C. A.* 17, 3184).

C. J. W.

Splitting of azimethines by mercuric chloride. GEORG SACHS. *Monatsh.* 46, 137-42 (1926).—Benzaldehyde-mercuric chloride, 2PhCH·NEt 3HgCl₂, decomp. 150°, results in 2.4 g. yield from 7 g. HgCl₂ and 8 g. PhCH·NEt in 400 cc. Et₂O. Equimol. amts. of HgCl₂ and PhCH·NEt in EtOH gradually ppt. EtNH₂·HgCl₂ (65% yield); the soln. contains BzH. The decompn. also occurs in moist Et₂O. Benzaldehyde-mercuric chloride, in 0.9 g. yield from 1.6 g. HgCl₂ and 1.5 g. PhCH·NCH₂Ph. PhCH·NCH₂Ph and HgCl₂ in moist Et₂O give 65% of PhCH₂NH₂·HgCl₂·PhCH·NPh (2 mols.) and HgCl₂ sep. 40% of the HgCl₂ as PhNH₂·HgCl₂. PhNH₂ gives the compds. PhNH₂·HgCl₂ or (PhNH₂)₂·HgCl₂, depending upon the proportions used. Benzaldehyde-mercuric acetate, m. 155-7°.

C. J. WEST

Isomerization of ethylene oxides and a comparison of the affinity capacities of some cyclic and acyclic radicals. TIFFENAU AND J. LÉVY. *Compt. rend.* 182, 391-3 (1926). Expts. have already shown (*C. A.* 19, 822) that in the isomerization of certain ethylene oxides, rupture of the O bond occurs on the side nearer to the radical with the greater affinity capacity. Further compds. were studied to det. whether this is a general characteristic. 1-Anisyl-2-phenylethylene oxide, MeOC₆H₄CH₂CHPh O prepd. from

BzO₂H and MeOC₆H₄CH₂CHPh, m. 118-9°, gives on distn. the isomer MeOC₆H₄CH₂COPh. 1,3-Diphenyl-2-benzyl-1,2-propene oxide, PhCH₂C(CH₂Ph)₂O, from BzO₂H

and PhCH₂CPh CHPh, thick liquid, b₃₆ 240-5°, gives on distn. at atm. pressure 1,2,4-triphenylbutanone. The results indicate that in the isomerization of di- or trisubstituted dissymm. ethylene oxides, the acyclic radicals have less affinity capacity than the cyclic radicals and that among the latter the anisyl radical has a greater capacity than the Ph radical. Though the affinity capacity of the Ph group increased by that of H is less than that of 2 Me groups, it is greater than that of 2 PhCH₂ groups.

C. C. DAVIS

p-Nitrobenzoyl esters of β -phenylethyl, γ -phenylpropyl and δ -phenylbutyl alcohols. W. R. KIRNER. *J. Am. Chem. Soc.* 48, 1111-2 (1926).—The *p*-nitrobenzoate of β -phenylethyl alc., m. 62-3°; of γ -phenylpropyl alc., 45-6°; of δ -phenylbutyl alc., 18-20°

These derivs. are no more suitable for identification purposes than are the phenylurethans.

The decomposition of cinnamaldehyde at high temperature by sudden heating. C. J. WEST, E. PEYTRAL. *Bull. soc. chim.* 39, 214-6 (1926); cf. *C. A.* 12, 579.—When PhCH:CHCHO (I) is passed rapidly through a hot tube 11.4% of the material appears in the form of a gas of the following compn.: CO (II) (73%), H (9%), C₆H₆ (III) (3.1%), CH₂:CH₂ (IV) (3.6%), C₂H₂ (V) (8.7%) and CH₄ (2.6%). The liquid products are III, styrene (VI), and unchanged I. In addn. some distyrene and free C are obtained. The decompn. of I into II and VI is the primary reaction (approx. 27%). VI then gives III and V. IV is explained as a reduction product of V. The other products indicate some more profound type of decompn.

REYNOLD C. FUSON
The reversible exchange of oxygen between aldehydes or ketones on the one hand and primary or secondary alcohols on the other hand. WOLFGANG PONNDORF. *Z. angew. Chem.* 39, 138-43 (1926).—PhCH:CHCHO and PhCH₂OH, in the presence of (PhCH₂O)₃Al, yielded PhCH:CHCH₂OH and BzH. Anisaldehyde and PhCH₂OH in the presence of PhCH₂ONa yielded anisyl alcohol and BzH. Citral and iso-PrOH in the presence of (iso-Pr)₃Al yielded geraniol, nerol and Me₂CO. Menthone and AmOH yielded menthol, valeraldehyde and valeric acid. Carvone and iso-PrOH with (iso-Pr)₃Al yielded carveol and Me₂CO. Menthol and PhCH:CHCHO yielded menthone and PhCH:CHCH₂OH in the presence of Al alcoholate. Refluxing PhCH:OH and anisaldehyde with no catalyst produced a partial reaction. The addn. of 5% AcONa increased the velocity of the reaction. The reaction is explained upon the theory that the aldehyde and alc. combine to form an unstable acetal, which decomp. to yield the new alc. and aldehyde. The reaction is thus reversible, and reaches a definite equil.

T. S. CARSWELL
The O-alkyl derivatives of benzoylacetone and the isoxazoles produced from them. (Reply to Mr. C. Weygand.) I. CLAUSEN. *Ber.* 59B, 144-53 (1926), cf. *W. C. A.* 20, 194.—Although in outward appearance, b. p. and d., the ether (I) obtained from BzCH₂Ac and HC(OEt)₃, to which C. assigned the A-ether structure, BzCH: C(OEt)Me, is very similar to the B-ether (II), PhC(OEt)CHAc, prepd from PhCHBrCHBrAc and alc. KOH, the 2 are not identical, as claimed by W. That both should give with NH₂OH·HCl the same isoxazole (III), m. 68°, is not surprising since the ethers, being exceedingly sensitive to acids, are very rapidly dealkylated by the HCl of the NH₂OH·HCl and the product obtained results from the action of the NH₂OH on free BzCH₂Ac. If this preliminary decompn. is avoided or the BzCH₂Ac is at once converted into a form which cannot react with NH₂OH, i. e., if free NH₂OH in the presence of an excess of alkali is used, II gives III almost exclusively while I yields 80-90% of the isoxazole (IV) m. 43°. The only by-product is an alkali-sol. substance, m. 98-9° (probably identical with W.'s product, m. 81-2°), which proved to be PhC(NOH)CH₂C(NOH)Me (V). Again, when I is heated some hrs. in a sealed tube at 100° with the calcd. amt. of NH₃ in MeOH the contents of the tube solidify on cooling to a compact cryst. mass of the A-amide, BzCH: C(NH₂)Me, m. 143°, while with II the contents of the tube remain fluid and only after evapn. of the MeOH does the *Bamide* sep. in prisms, m. 86-7°, which dissolve in cold concd. HCl and sep. again on standing as an HCl salt, but on gentle warming they decomp. quickly into NH₄Cl and BzCH₂Ac. IV heated with concd. H₂SO₄ becomes deep brown-black about 270°, finally carbonizes and evolves SO₂ while III can be heated to boiling without any appreciable color. Both III and IV in about 10% alc. soln. give with alc. CdCl₂ white cryst. ppts., C₁₀H₉ON·CdCl₂; with 20% alc. HgCl₂ III solidifies in about a min. to a magma of fine crystals while with IV nothing seps. in 24 hrs. With PhMgBr III gives BzCH: C(NH₂)Me and Ph₂. III and IV are very stable towards alkalis, neither long boiling or heating under pressure with alc. KOH nor distn. from soda-lime produces any change or a rearrangement of the one into the other. Benzoylacetone dioxime (V) gives a faint yellow color with FeCl₃, is smoothly converted into III by short boiling with HCO₂H. W.'s supposed Me B-ether, obtained from BzCH₂Ac with CH₃N₂ is in reality a mixt. of (about 2/3) A-ether and a smaller amt. of B-ether, as shown by conversion into the amides and isoxazoles.

C. A. R.

by direct transference of O to another substance. Non-hydrolyzed Bz_2O_2 can liberate I from KI when it is sufficiently sol. in the medium, not by oxidation in the true sense, but by rupture of the O bridge: $(RCO)_2O_2 + 2KI = 2RC_2OK + I_2$. When 0.3616 g. Bz_2O_2 in 10 cc. Me_2CO is treated with 25 cc. of an equimol. Me_2CO-H_2O mixt. at 13° and 5-cc. portions are added at definite time intervals to acidified aq. KI and at once titrated with 0.397 N $Na_2S_2O_3$, 0.2, 0.15, 0.15, 0.15 cc. of the latter are required after 2, 13, 45 min. and 12 hrs., resp., *i. e.* there is no appreciable hydrolysis of the Bz_2O_2 to Bz_2OH ; if the aliquot is added to an aq. Me_2CO instead of an aq. soln. of KI, so that the Bz_2O_2 , instead of being pptd., remains in soln., the calcd. amt. of I is instantly liberated. If KI-starch is added to an aq. suspension of Bz_2O_2 a blue color gradually develops, not as a result of hydrolysis of the Bz_2O_2 but produced directly by the traces of it which dissolve; the reaction is impeded by a little AcOH and especially by HCl. A moderately concd. Me_2CO (or aq. alc.) soln. of Bz_2O_2 added to an aq. Me_2CO soln. of KI strongly acidified with concd. HCl liberates I instantly, while with KBr a neutral soln. instantly liberates Br and a HCl soln. only slowly. Finally Bz_2O_2 with NaI in abs. Me_2CO instantly liberates the calcd. amt. of I and NaOBz seps. in gel form; with NaBr the reaction is less smooth. Basic substances very markedly accelerate the hydrolysis of Bz_2O_2 to Bz_2OH , but they may also possibly react with the Bz_2O_2 ; at least, this seems to be the case with NH_3 , for when Bz_2O_2 in aq. Me_2CO is treated with an excess of concd. NH_4OH and at once poured into much H_2O contg. acidified KI-starch a blue color at once appears, owing to the presence of Bz_2OH formed according to the scheme $Bz_2O_2 + NH_3 \rightarrow BzNH_2 + Bz_2OH$. *Addendum. Iodometric detn. of Bz_2O_2 .* 0.2 g. of the sample in 10 cc. pure Me_2CO is treated with 3 cc. concd. aq. KI (faintly acidified if necessary), dild. with a little H_2O and immediately titrated. C. A. R.

Synthesis of the ethyl ester of *p*-aminobenzoic acid. MATAJIRO WATANABE *Gun. D. Z., Tokyo* 889-95(1923); *Japn. J. Med. Sci.* 2, 22.—Treat $p-H_2NC_6H_4CO_2H$ or its salts with iso-BuOH or iso-Bu halide, or reduce $p-O_2NC_6H_4CO_2CH_2CHMe_2$ or its azo compd. H. G.

The value of by-products of saccharin manufacture in analytical chemistry. WALTHER HERZOG. *Osterr. Chem.-Ztg.* 29, 26-7(1926).— $p-MeC_6H_4SO_2NClNa$ (I), when in contact with acceptors of O, decomps. quant. into $p-MeC_6H_4SO_2NH_2$, NaCl and O. A soln. of 15 g. I in 1 l. H_2O gives a 0.1 N Cl soln. of great stability. EtOH or Me_2CO is detected in 1:10,000 solns. by treating 10 cc. of liquid with 0.1 g. I and KI in alk. soln., when CHI_3 is formed. Treatment of $p-MeC_6H_4SO_2NH_2$ with I in KI yields $p-MeC_6H_4SO_2NKI$, which decomps. in H_2O to give HIO, and can be used to estimate phenols, etc. T. S. CARSWELL.

Photochemistry of some cinnamic acid derivatives. HANS STOBBE. *Ber.* 58B, 2859-63(1925).—Solid $PhCH:CHCO_2Me$ (I), m. 33.4° , exposed 6 months to sunlight during the sunny summer of 1921 yielded a mass consisting of 96.8% unchanged I, 0.2% of Liebermann's amorphous polyester (II) (C. A. 5, 2250) and 2.9% of the cryst. easily saponif. Me α -truxillate (III), m. 174° . The II is supposed to be formed from fused I during the warmer parts of the day and the III from the solid I during the cooler parts. *trans*- $PhCH:CHCONH_2$, m. 141.5° , after 5 months gives 75% of α -truxill diamide, m. 266° , also formed in HCl suspension (25:1). The absorption spectra of alc. solns. of the 2 amides are very similar to each other, and the same is true of the spectra of the 2 acids. *trans*- $PhCH:CHCONHPh$, m. 150° , is not polymerized by exposure to sunlight, in dry form or in HCl suspension, for 6 months or by 500 hrs. illumination between glass or uvioil plates. The isomerism of *allo*-cinnamic anhydride in the dark into the *trans*-anhydride is accelerated by heat and light; a sample exposed 9 weeks to sunlight or to a quartz Hg lamp contained 80% *trans*- and 20% *allo*-anhydride. The *trans*-anhydride is in small part resinified on illumination but for the most part remains unchanged. $PhCH:CHCHO$ in sealed glass tubes under 17-mm. pressure gave after 8 months in sunlight a mass contg. 60% unchanged aldehyde, 33% $PhCH:CHCO_2H$ and 7% of Ciamician and Silber's polyaldehyde, m. $103-12^\circ$ (C. A. 5, 3239), which is apparently a tetramer (mol. wt. (Rast) 500-571), is easily depolymerized on dry distn., reduces $KMnO_4$ in AcOH but forms no oxime and does not react with NH_4AgNO_3 or fuchsin- SO_2 . $PhCH:CHBrCO_2H$ after 7 months in sunlight or 375 hrs. exposure to a quartz Hg lamp is 91% unchanged, the remainder being converted by autooxidation into $BzOH$, $(CO_2H)_2$, and free Br. $PhCHBrCHBrCONH_2$ undergoes dimerization but the anilide does not. The above results show how great an influence slight mol. changes have on the photochem. behavior of these structurally closely related substances. C. A. R.

Influence of different substituents on the firmness of the union of carboxyl groups in substituted aromatic acids. Influence of a second carboxyl group and relative effect

of chlorine and bromine. FRANZ HEMMELMAYR AND THEA MEYER. *Monatsh.* **46**, 143–56 (1926); cf. *C. A.* **7**, 1705.—*Bromo- α -resodicarboxylic acid (I)*, m. 303°, crystg. with 1.5H₂O, gives a red Fe reaction; *Ba salt*, with 10H₂O; *Ag salt*, *Dibromo- β -resodicarboxylic acid*, m. 245°, crystg. with 1.5H₂O, gives a blue-violet Fe reaction; *Ba salt*, 2H₂O; *Ag salt*. *Chloro- β -resorecylic acid*, m. 175°, gives a violet Fe reaction; *di-Cl deriv.*, m. 229°, gives a carmine-red Fe reaction; *Ba salt* with 1.5H₂O, *Ag salt*. *Chloro- α -resodicarboxylic acid (II)*, m. 297° (decompn.), gives a red Fe reaction, crysts. with 2H₂O; *Ba salt*, with 7H₂O; *Ag salt*. Nitration of α -resodicarboxylic acid gives styphnic acid Fe reaction; a NO₂ deriv. was not obtained. *Di-Me ether of di-Me β -resodicarboxylate*, m. 122°; nitration gave negative results. Tables are given showing the amt. of CO₂ split off from various aromatic acids upon cooking with H₂O and with PhNH₂: 3,5-(HO)₂C₆H₃CO₂H, 100% in both, 2,4-(HO)₂C₆H₃CO₂H, 49% in H₂O, 95% in PhNH₂, 2,6-(HO)₂C₆H₃CO₂H, 36% in H₂O, 2,5-(HO)₂C₆H₃CO₂H, 33% in PhNH₂, 2,3-(HO)₂C₆H₃CO₂H, 89% in PhNH₂, 2,6,1,3-(HO)₂C₆H₂(CO₂H)₂, 7.8 in H₂O, 100% in PhNH₂, 3,5,1,2-(HO)₂C₆H₂(CO₂H)₂, 4% in H₂O, 18% in PhNH₂, 2,5,1,4-(HO)₂C₆H₂(CO₂H)₂, 11% in PhNH₂, 2,3,1,4-(HO)₂C₆H₂(CO₂H)₂, 81% in PhNH₂. α -Resodicarboxylic acid splits off 100% CO₂ in PhNH₂, the β -Br deriv., 96%, the β acid, 48%, and its 4,6-Br deriv., 18.5%. Chloro- β -resorecylic acid splits off 65% CO₂ in PhNH₂; the Br deriv., 93%, the di-Cl deriv., 89%; in H₂O the di-Cl deriv. splits off 62%, the di Br deriv., 85%. I in PhNH₂ splits off 96%, II 86% CO₂.

Gallocarboxylic acid trimethyl ether. K. FEIST AND W. AWE. *Ber.* **59B**, 175–7 (1926).—The m. p. of different preps. of 2,3,4,1,5-C₆H₃(OMe)₂(CO₂H), had been found to vary from 176–7° to 195° (cf. *C. A.* **13**, 1453). The acid was accordingly prep'd again both from gallic acid and from 2,3,4-(HO)₃C₆H₂CO₂H. The intermediate *di Me ester* in both cases m. 35.4° (cor.) and gave an acid which, on recrystn. from H₂O, m. 189–90° (cor.), from MeOH 191°, from CHCl₃ 189°, from Me₂CO 191.5°. The identity of the acids (and esters) obtained from both sources was shown by mixed m.p.s, titration, analysis and MeO detns.

Acylation of aromatic hydroxycarboxylic acids. RUDOLF LESSER AND GEORG GAD. *Ber.* **59B**, 233–6 (1926).—The acetylation of hydroxycarboxylic acids with Ac₂O in aq. alk. soln., observed in the case of 2,4-C₆H₃(OH)(CO₂H) (*C. A.* **20**, 1233), has now been found to be a general reaction except when the HO group is in the *o*-position to the CO₂H group; in fact, the reaction may be used to detect the presence of an *o*-HO group in poly-HO acids and to prep. partially acetylated derivs. of such acids. The yields are in part quant. and only a slight excess of Ac₂O is required. Thus, *p*-AcOC₆H₄CO₂H, m. 191–2°, is obtained in 6 g. yield from 5.6 g. *p*-HOC₆H₄CO₂H in 80 cc. *N* NaOH at about 40° treated dropwise with 5 g. Ac₂O, stirred 1 hr. longer (finally in ice) and acidified with AcOH, and the *m*-acid in the same way gives the same yield of its acetate, m. 128°. From 1.5 g. 2,4-(HO)₂C₆H₃CO₂H is obtained 4.2 g. *2-hydroxy-4-acetoxybenzoic acid*, m. 152–3°, gives with FeCl₃ the violet salicylic acid reaction while the di-HO acid gives a Bordeaux-red color, 5 *iso* isomer (1 g. from 4.5 g. 2,5-(HO)₂C₆H₃CO₂H), m. 131–2°, likewise gives a violet color with FeCl₃, as against the steel-blue color given by the di HO acid. *3,5-Diacetoxybenzoic acid* (3.5–4.0 g. from 4.5 g. of the di-HO acid), m. 152–3° and, like the di HO acid, gives no color with FeCl₃. 3,4-(HO)₂C₆H₃CO₂H with somewhat more than 2 mols. Ac₂O gives almost quant. the diacetate, m. 157–8°, but 4.5 g. of the di HO acid in 5 cc. H₂O and 15 cc. of 2 *N* NaOH treated in ice simultaneously with 15 cc. more NaOH and 3 g. Ac₂O so that the soln. never becomes alk. yields 4.5 g. of a monoacetate, m. 199°, which does not react with FeCl₃ and is probably identical with the 3-acetate, m. 202–3°, obtained by partial sapon of the diacetate (Fischer, Bergmann and Lipschitz, *C. A.* **12**, 1968). Gallic acid (5.7 g.) with 70 cc. 2 *N* NaOH and 12 g. Ac₂O gives 91% of the triacetate, m. 171–2°, while with 3 mols. NaOH and 2 mols. Ac₂O 10 g. gives 5 g. of the 3,5-diacetate hydrate, m. 174–5°, and from 10 g. of the tri HO acid in 8 cc. of 38% NaOH and 25 cc. H₂O with 6 g. Ac₂O is obtained 4.5 g. of the 3-acetate, m. 226–7°, gives a dark blue-green color with FeCl₃, undoubtedly identical with the compd. obtained by F., B. and L. as a by-product. *4-O-Acetylphloroglucinalcarboxylic acid* (3 g. from 8.2 g. of the K. salt of the tri-HO acid in H₂O treated in ice simultaneously with 20 cc. of 2 *N* NaOH and 4 g. Ac₂O), m. 177–8° (decompn.), gives, like the tri HO acid, a violet blue color with FeCl₃; if the acetylation is carried out at room or higher temp. or if the reaction mixt. is not very cautiously acidified after the acetylation, CO₂ is evolved and the chief product is sym-C₆H₃(OAc)₃, m. 105–6°.

Preparation of *o*-phthalaldehydic acid. R. C. FUSON. *J. Am. Chem. Soc.* **48**, 1093–6 (1926).—The oxidation of C₁₀H₈ to *o*-HO₂CC₆H₄COCO₂H by KMnO₄ gives the

best yields when 32 g., suspended in 0.5 l. *N* NaOH, is gradually treated with 212 g. KMnO_4 in 1.5 l. H_2O over a period of 2.5 hrs.; the aq. soln., concd. to 500 cc. and heated with 100 g. PhNH_2 for 1 hr., gives 80-5% of the aniline deriv. of phthalonic acid, m. 165° ; it probably has the structure $\text{O.CO.C}_6\text{H}_4.\text{C}(\text{NHPh})\text{CO}_2\text{H}_2\text{NPh}$. Boiled with per-

fectly dry $\text{C}_6\text{H}_4\text{Me}_2$, the salt decomps. in a few min., giving practically quant. *o*-carboxybenzylidene-aniline (I), while it remains unchanged even after hrs. of boiling in $\text{C}_6\text{H}_4\text{Me}_2$ contg. only 0.4% H_2O . Hydrolysis of I with 10% HCl gives $\text{o-HO}_2\text{CC}_6\text{H}_4\text{CHO}$ in 80% yields (65% of the C_{10}H_8 used). The acid may also be obtained from *o*-cyano-benzal bromide, m. $62-3^\circ$, by boiling 4 hrs. with dil. H_2SO_4 but the method is unsatisfactory because of the great difficulty encountered in introducing the 2nd Br atom into *o*- $\text{MeC}_6\text{H}_4\text{CN}$.

C. J. WEST

The existence of isopulegone in the natural state. Isolation of α -(iso) and β -(ordinary) pulegones and their enols in the pure state. V. GRIGNARD AND J. SAVARD. *Compt. rend.* 182, 422-5(1926).—Though it has already been shown (C. A. 20, 751) that isopulegone (α -form) (I) is present in natural pulegone, sepn. of I and the β -form (II) has heretofore been impracticable. II, however, combines with NaHSO_3 while I is unattacked, and this difference in behavior was utilized to effect a sepn. of I and II in the pure state. The sepn. is slow and the natural pulegone should be agitated at least 1 month with 2 vols. of NaHSO_3 (36° Bé.) and 0.5 vol. of EtOH , and as the addn. compd. is formed it is filtered and the filtrate is treated with more NaHSO_3 until no more is formed. I is extd. with H_2O , pptd. with H_2O and extd. in turn with Et_2O . Traces of II are removed by reducing it with Al-Hg (cf. *Ber.* 32, 3357(1899)). Two samples (Schimmel and Bernard-Escoffier) of oil of *Mentha pulegium* contained 18 and 16% resp. of I, which when pure b_p 78° , d_{14}^{20} 0.9097, n_D^{20} 1.46332, $[\alpha]_D$ 34.03°, R_M 46.05. *HBr* salt, m. 48° , decomps. readily. Since both this and the *HBr* deriv. of II are 8-bromo-3-*p*-menthanone, they should have enantiomorphous forms. The enol form of natural pulegone previously prepd. (C. A. 19, 1136) was a mixt. of the enols of 2 isomers (I and II). On sepn. of the 2 enolic compds., the following data were obtained: enol form of I (from natural pulegone) b_p $80-1^\circ$, d_{14}^{20} 0.8965, n_D^{14} 1.46732, R_M 47.25, $[\alpha]_D$ -4.3° ; enol form of synthetic I, b_p 81° , d_{14}^{20} 0.8966, n_D^{14} 1.46754, inactive; enol form of II (from natural pulegone), b_p 88° , d_{14}^{20} 0.9160, n_D^{13} 1.48312, R_M 47.40, $[\alpha]_D$ 24.6° . Natural I is therefore identical with that obtained by the isomerization of II. The α -enols can be prepd. like the β -enols and they have the same stability. The values of $[\alpha]_D$ of the α - and β -enols indicate in each case a conjugation of the double bonds.

C. C. DAVIS

Some derivatives of 1,1'-bismenthone. P. G. CARTER AND JOHN READ. *J. Soc. Chem. Ind.* 45, T44-6(1926).—1,1'-bismenthone (I), m. $157-8^\circ$, was prepd. by acting upon piperitone in alc. with Na-Hg . Reduction of I with Na in alc. yielded 1,1'-bismenthol, m. $179-82^\circ$ after recrystn. from alc.; phenylurethan, m. $198-200^\circ$; diacetate, m. $111-2^\circ$. Heating I with $\text{NH}_2\text{OH.HCl}$ yielded 1,1'-bismenthone oxime (II), m. $238-40^\circ$. Reduction of II with Na in alc. yielded 1,1'-bismenthylamine; *HCl* salt, unmelted at 250° . *di-Bz* deriv. darkens 210° , decomps. 245° ; dibenzylidene and disalicylidene derivs., unmelted at 270° .

T. S. CARSWELL

Orientation effects in the diphenyl series. I. H. G. DENNETT AND E. E. TURNER. *J. Chem. Soc.* 1926, 476-81.—(4- BrC_6H_4)₂ on nitration gives the 2-nitro deriv., m. 124° (cf. Lellmann, *Ber.* 15, 2837), also prepd. from 2-nitrobenzidine through the diazo reaction. Further nitration gives the 2,3'-dinitro deriv., m. 148° , which with piperidine gives 4-bromo-4'-piperidino-2,3'-dinitrodiphenyl, orange red, m. $136-7^\circ$; the 2-NO and the 2,2'-(NO)₂ derivs. do not give this reaction. Disalicylidene-4,4'-dibromo-2,3'-diaminodiphenyl, yellow, m. 195° . 4-Chloro-4'-piperidino-2,3'-dinitrodiphenyl, orange, m. 132° . Mononitro-4,4'-ditolyl, yellow, m. $91-2^\circ$; further nitration gives the 2,3'(?)-dinitro deriv., yellow, m. 119° . Disalicylidene-3,5'-diaminodiphenyl, canary yellow, m. $176-7^\circ$. *p*-Nitrobenzylidenesalicylidenebenzidine, yellow, m. 210° . *p*-Nitrobenzylideneacetylisopropylidenebenzidine, brownish yellow, m. 185° . This work is the first example of unsym. substitution in the Ph_2 series.

C. J. WEST

Reduction of oximes by means of sodium and absolute alcohol. Resolution of the racemic amines obtained into their optical antipodes by means of *d*-tartaric acid. P. BILLON. *Compt. rend.* 182, 470-3(1926).—Hydrogenation by the method of Bouveault and Blanc (cf. Billon, C. A. 19, 816) was found to give almost theoretical yields of amines (in no case below 85%) from the corresponding oximes. The ketones whose ketoxime derivs. were tested included both those with 2 different aryl groups and those

with an aryl and an alkyl group. *p*-Tolyl Ph ketoxime gave quant. *p*-tolylphenylaminomethane, m. 40°, b₇₆₀ 296°, b₁₄ 172°, this being the first time it had ever been obtained in cryst. form. *HI* salt chars at about 250°. *p*-Anisyl Ph ketoxime and EtC(:NOH)Ph a quant. yield of the corresponding amine reduction product. Only plished by successive crystns. of the *d*-tartaric acid deriv., m. 166°, from abs. EtOH. *d*-Compd., m. 180°, [α] 9°30'; *l*-compd., m. 195°, [α] -10°30'. Supplementary tests on the reduction of Ph₂C:NOH gave the amine quant.

C. C. DAVIS

Thymolsulfonephthalein, the intermediate acid, 4'-hydroxy-3'-isopropyl-6'-methylbenzoylbenzene-2-sulfonic acid and some of their derivatives. W. R. ORNDORFF AND R. T. K. CORNWELL. *J. Am. Chem. Soc.* **48**, 981-983 (1926) — Condensation of thymol (I) and ClOCC₆H₄SO₂Cl with or without condensing agents (ZnCl₂, AlCl₃) gave only 10-15% of thymolsulfonephthalein (II), the main product being *dit*hymyl *o*-sulfobenzoate, m. 102-3°, slowly saponif. by boiling aq. and cold EtOH KOH, it could not be trans. formed into II by AlCl₃ or SnCl₄. I and the acid anhydride with ZnCl₂ at 105-10° for 30 hrs. give 55% of II and 4'-hydroxy-3'-isopropyl-6'-methylbenzoylbenzene-2-sulfonic acid, crystg. with 2H₂O; an aq. soln. gives a blue color with aq. FeCl₃; above 150° it slowly decomp.; with ZnCl₂ at 85° it gives II. NH₄ salt, Ba salt (crystallographic data); *di*-Bz deriv., m. 119-20°. II crysts. with about 1 mol. H₂O; color changes and qual. soly. in various solvents are discussed. The chocolate-brown powder loses water at 59°, turns red at 195°, carbonizes slightly between 200-20° and then melts to a crimson, opaque liquid. *NH₄* salt, red; the dry powder absorbs 3 mols. NH₃, giving a purple color; 2 of the NH₃ mols. are lost *in vacuo* over H₂SO₄. Zn salt, orange-red plates with 5H₂O; the red soln. in H₂O changes to yellow on diln. *Mono*-Na salt, orange-red, with about 1 mol. AcOEt; anhyd. brown and hygroscopic. *Di* Na salt, dark blue, with 2EtOH. *Di*-Ac deriv., m. 171-2°, *di*-Bz deriv., m. 194-5°. The *di*-Me ether turns red at 195° and m. 201-2°; heated at 180° for 2 min. there results a deep purple form, changing to the colorless form upon recrystn. from or in contact with MeOH. *PhNH₂* salt, brown needles, by heating I in PhNH₂ for 12 hrs. at 115-20°. On adding H₂O to the filtrate there ppts. the *dianilino* deriv., dark green, almost black needles. The *di*-Br deriv. of II, decomp. 130-5°, crysts. with 2H₂O as purple crystals grinding to a red powder. One mol. of NaOH may be added to its soln. before the end point is reached. *Di*-Ac deriv., m. 222-3°. II and Zn dust in H₂O, boiled until soln. results and the product is colorless, give *thymolsulfonephthalein*, crystg. with about 3.5 mols. H₂O, m. 134-5°, isolated as the Zn salt, crystg. with 8H₂O. The free acid is less stable than the Zn salt, oxidizing quickly in the light; it is very sol. in H₂O and the soln. is easily oxidized by bubbling air through it.

C. J. WEST

4- and 4'-Methoxybenzoylbenzoins. HERBERT GREEN. *J. Chem. Soc.* **1926**, 328-36. — Furfuraldehyde, BzCl and KCN in H₂O, shaken 1 hr. with cooling, give practically quant. *benzoylfurfuraldehyde cyanohydrin* (I), m. 49°. A mixt. of this (11 g.) and furfuraldehyde (12 g.) treated with EtONa, gives 7.35 g. *benzoylfuroin* (II), m. 92-3°; cold concd. H₂SO₄ develops an intense green color, becoming brown on warming; the action of EtOH-NaOEt gives a small amt. of furil, m. 161°. Benzofuroin is not benzoylated by BzCl and KOH or C₆H₅N, heating with BzCl alone results in profound decompn. Benzofuroin is the only product of the interaction of benzoylmandelonitrile (III), furfuraldehyde and EtONa, the EtONa being added through 5-6 hrs. Attempts to prep. isomeric benzoylbenzofuroins from I and BzH and III and furfuraldehyde gave mixts. of benzoylbenzoins and II; and equimol. mixt. of these 2 compds. begins to m. 85.5° and still contains some solid at 90°. The 4'-methoxybenzoylbenzoins, m. 119.5-20°, described by G. and Robinson (*C. A.* **17**, 90) is now considered the 4-deriv. It is best prepd. from benzoyl-*p*-methoxymandelonitrile and BzH with a little more than 1 mol. EtONa, the reaction being interrupted after 10 min. This also results in 0.9 g. yield from 12 g. III and 11 g. *p*-MeOC₆H₄CHO, to which was added in 1 lot 13 g. Na in 25 cc. EtOH and the reaction checked after 7 min. In certain preps. of the 4-deriv., benzoylbenzoins was obtained in small amts. 4'-Methoxybenzoylbenzoins, m. 127-8°, results from 23 g. III, 22.5 g. *p*-MeOC₆H₄CHO and 1.15 g. Na in 30 cc. EtOH, the reaction being checked after 5 min; cold concd. H₂SO₄ gives a brassy yellow soln., changing on warming through reddish brown to dark greenish brown. Benzoylmethylenedioxymandelonitrile (IV), furfuraldehyde and EtONa give *piperonyl- α -furylcarbonyl benzoate*, m. 132.5-3.5°; increasing the reaction time from 5 to 20 min. decreases the yield somewhat and an increase in the amt. of Na used gives an impure product. Condensation of piperonal and I with EtONa gives *α -furylpiperonylcarbonyl benzoate*, m. 140-1°; the concd. H₂SO₄ soln. is intensely crimson. III and piperonal are condensed

by EtONa to 3',4'-methylenedioxybenzoylbenzoin, while IV and BzH give the 3,4-isomer.

C. J. WEST

Remarks on the communication of R. Lesser, E. Kranepuhl and G. Gad on the constitution of naphthalene and its derivatives. K. FRIES. *Ber.* 58B, 2845-51 (1925).—According to L., K. and G. (*C. A.* 20, 909) the peculiar behavior of 2,3-C₁₀H₆(OH)CO₂H (I) and its derivs. indicates that they have a double bond between C atoms 2 and 3, this "so to speak forced" position of the double bond in the C₁₀H₈ nucleus explaining the tendency of such derivs. to change into β,β-quinonoid compds., while 2,3-C₁₀H₆(OH)₂ (II), which it has hitherto not been possible in any way to convert into a 2,3-naphthoquinone, would have the normal structure with a double bond between C atoms 1 and 2. I, however, can be degraded to a 2,3-C₁₀H₆(OH)NH₂ (III), which in no way differs from that obtained from II, and there are no indications in the literature, to F.'s knowledge, that β,β-derivs. of C₁₀H₈ can exist in 2 isomeric forms. In 2,1- and 1,2-C₁₀H₆(OH)CO₂H the CO₂H group is replaced by other substituents on treatment with HNO₃, HNO₂, halogens or diazonium salts, and I should behave in the same way if the double bond is between the C atoms carrying the HO and CO₂H groups, but it does not; it is a true β-C₁₀H₇OH deriv. and, like the naphthol, is easily substituted, the 1st substituent always entering position 1. Moreover, the yellow 1,2,3-C₁₀H₆(OH)₂CO₂H, in which, on account of its color, L., K. and G. assume there is a double bond between C atoms 2 and 3, is readily oxidized to 1,2-naphthoquinone-3-carboxylic acid and the structure they assign to I can therefore not be correct. Chloride of I, from the K salt with SOCl₂ in C₆H₆ below 25°, intensely lemon-yellow, m. 99°, much more sensitive to moisture than 2,3-C₁₀H₆(OMe)COCl; amide, m. 217°. If I is heated with 10 parts SOCl₂ at 90° and then 110° it dissolves in 5 hrs. and yields 1-chloro-2-hydroxy-3-naphthoyl chloride, golden yellow, m. 128°, giving with MeOH the *Me ester*, yellow, m. 116°, and with NH₃ the *amide*, yellow, m. 225°. 2-Carbethoxy deriv. of I, from I and ClCO₂Et, m. 141°, chloride, m. 65°; *Me ester*, m. 60°; *amide*, yellowish, loses EtOH on heating above 100° or on boiling in AcOH with formation of 1,4-diketo-3,4-dihydro-*lin-naphtho-1,3-oxazine*, C₁₀H₈CO.NH.CO O, m. 300°, obtained directly from the amide of I with

ClCO₂Et in cold C₆H₅N, not attacked by acids and dil. alkalis, evolves NH₃ on boiling with concd. alkalis and yields I on acidification. *Acide* of I, from the hydrazide in ice H₂O suspension with exactly the calcd. amt. of NaNO₂ and dil. AcOH, yellow, m. 133°, explodes immediately afterwards (yield, 70%), gives in C₆H₆ on the H₂O bath 90% of 2-hydroxy-3-naphthyl isocyanate, yellow, m. 205°, which with 25% KOH on the H₂O bath gives 65% of III. *Me 2-hydroxy-3-naphthylcarbamate* (85% from the azide in MeOH on the H₂O bath), faintly yellow, m. 201°, gives with concd. HCl in sealed tubes at 120° 70% of III. 1,6-Di-Br deriv. of I, from the mono-Br deriv. in AcOH with excess of Br on the H₂O bath, yellow, m. 246° (decompn.), forms a rather difficultly sol. Na salt, gives on further bromination in AcOH a "keto bromide" if NaOAc is present, otherwise 1,6,8,3-C₁₀H₄Br₃CO₂H, m. 320°. C. A. R.

Acetonaphthols. II. K. FRIES AND K. SCHIMMELSCHMIDT. *Ber.* 58B, 2835-45 (1925); cf. *C. A.* 15, 2865.—It was found in the earlier work that β-C₁₀H₇OAc with AlCl₃ gives only 1,2-C₁₀H₆AcOH (I) whereas Witt and Braun reported that β-C₁₀H₇OMe (II) with AcCl gives 3,2-C₁₀H₆AcOMe (III). F. pointed out that their proof of the constitution of their compd. was based on a false assumption but since a C₁₀H₆AcOH prep'd. by their method lowered the m. p. of his, he concluded that their compd. really was III. Later, it was found that when their directions are followed exactly the product is a mixt., not easily sep'd., of 1,2-C₁₀H₆AcOMe (IV), with much unchanged II. III has now been synthesized and found to be entirely different from W. and B.'s product. They therefore undoubtedly obtained IV and their supposed methyl-β,β-naphthindazole was really 3-methyl-4,5-benzindazole (V). IV, m. 58°; *benzal deriv.*, yellow, m. 139°, gives a wine-red color with concd. H₂SO₄; *hydrazone*, leaflets with faint greenish yellow shimmer, m. 130°, gives, after standing 3 hrs. in the least possible amt. of concd. H₂SO₄, 30% of V, m. 216°, which is unchanged by hot concd. HCl or by concd. KOH. 2,3-C₁₀H₆(OMe)CO₂Me, b₁₈ 191°, m. 49°; the free acid (VI) is colorless and when slowly distd. under atm. pressure rearranges into the yellowish 2,3-C₁₀H₆(OH)CO₂Me, m. 72°. 2-Methoxy-3-naphthoyl chloride, from the K salt of VI refluxed with SOCl₂ in C₆H₆ (yield, around 50%), faintly yellow, b₁₇ 200°, m. 57°, gives with MeI, AcOEt and Zn-Cu in cold PhMe 2-methoxy-3-acetonaphthalene (II), b₂₀ 210-2°, m. 48° (*benzal deriv.*, faintly yellow, m. 121°). 2-HO comp'd. (8 g. from 10 g. III with AlCl₃ in C₆H₆ on the H₂O bath), yellow, m. 112°; *Na salt*, yellow, is not oxidized by the air even in soln.; *acetate*, m. 101°; *hydrazone*, faintly yellow, m. 144°, cannot be converted into an indazole. 2,6-C₁₀H₆(OMe)Ac (VII) can be obtained in 50% yield by treating β-C₁₀H₇OH in AcOH

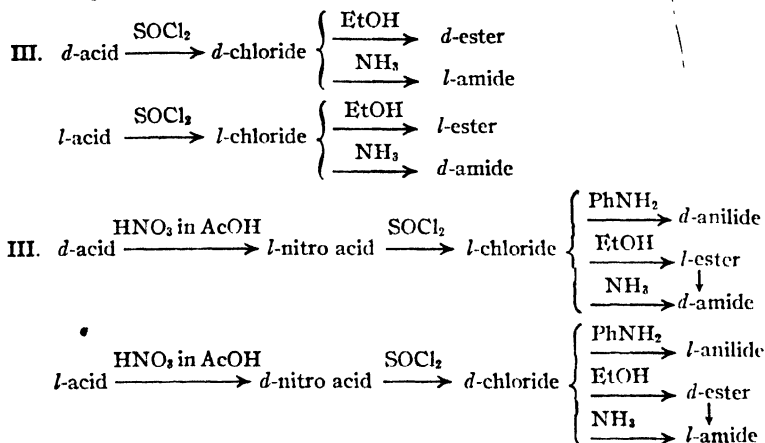

with Br-AcOH, boiling the resulting 1,6,2- $C_{10}H_6Br_2OH$ in alc. with Sn, concd. HCl and a little $CuSO_4$, methylating the 6,2- $C_{10}H_6BrOH$ in KOH with Me_2SO_4 , and treating the $C_{10}H_6BrOMe$ (yield, 50%) in $C_6H_5Et_2O$ on the H_2O bath with Mg and EtBr and sinters 190°, m. 209°; *chloride*, m. 101°; *amide*, m. 216°. 2-Methoxy-6-acetonaphthalene (VII), from the chloride with $MeZnI$, m. 105°, sol in concd H_2SO_4 with yellow color, converted by $AlCl_3$ in xylene on the H_2O bath into the 2-HO compd, m. 172°. In the that to hydrazone formation; in attempting to convert the resulting ketazines into indazoles with concd. H_2SO_4 , it was found that there were formed, instead, SO_3H acids, [1,4,2- $C_{10}H_6(OH)(SO_3H)CR:N$], which with dil. acids give N_2H_4 and 1,2,1- $C_{10}H_6(OH)(COR)SO_3H$. Azine from 1,2- $C_{10}H_6(OH)COEt$, from the ketone in boiling solu. gradually treated with $N_2H_4 \cdot H_2O$ until there is no further deposition of azine on long boiling, red, m. 232°, hardly attacked by concd. HCl or alkalis, *di-Ac deriv.*, yellow, m. 139°; 4-sulfonic acid, from the azine allowed to stand 24 hrs. in 2.5 parts concd. H_2SO_4 , red, m. 234–40° (decompn.), very hygroscopic. 2-Propionyl-1-naphthol-4-sulfonic acid (VIII), best obtained directly from the $C_{10}H_6(OH)COEt$ allowed to stand 24 hrs. in 2.5 parts concd. H_2SO_4 , very hygroscopic, m. 127° (decompn.), pptd by concd. HCl from the yellowish NaOH solu., unchanged by concd. HCl at 100° but converted into the $C_{10}H_6(OH)COEt$ when distd. from its solu. in concd. H_2SO_4 only slightly dild with H_2O ; with the calcd. amt. of Br in AcOH it gives 4-bromo-2-propionyl-1-naphthol, yellow, m. 97°, while with twice as much Br is obtained 4-bromo-2-bromopropionyl-1-naphthol, yellow, m. 138°, sol. in alkalis without change, converted by 3 times the calcd. amt. of boiling 10% NaOH into 2-methyl-3-keto-5-bromo-6,7-benzonouran, yellowish, m. 106°, sol. in concd. H_2SO_4 with yellow color. Azine from 1,2- $C_{10}H_6(OH)COMe$, red, m. above 300° (decompn.); 4-sulfonic acid, yellow hydrated substance changed by rubbing with glacial AcOH into red crystals turning brown 120°, m. 233.6° (decompn.), could not be obtained absolutely anhyd. as it slowly decomp. on drying at 100°. 2-Aceto-1-naphthol-4-sulfonic acid, m. 127°, does not depress the m. p. of VIII. 1-Aceto-2-naphthol Et ether, from I with EtBr and NaOEt, m. 61°, identical with the product described by W. and B. as 3,2- $C_{10}H_6AcOEt$. The following compds. are also erroneously described as 3-acetonorolin derivs. in the literature: 1-benzalaceto-2-naphthol Et ether, m. 90°; *p-anisal analog*, m. 102°; 2-ethoxy-1-naphtholformic acid, m. 162°; 2-ethoxynaphthalene-1-carboxylic acid, m. 147°.

C. A. R.

The α - and β -naphthoxymethylacetic acids, their mononitro derivatives and optical isomers. ERNEST FUORNEAU and BALACEANO. *Bull. soc. chim.* 37, 1602–28 (1925).—*dl- α - $C_{10}H_7OCH_2CH_2CO_2H$* (I), m. 152.3°, was prepd. in 85% yield from the Et ester. This latter, from $C_{10}H_7ONa$ and $BrCH_2CH_2CO_2Et$ (II), b.p. 205°. Acid chloride prepd. from I and $SOCl_2$. *Amide*, from the chloride and NH_3 in dry Et_2O , m. 152°, and is sapond. by prolonged boiling with alc. KOH. *Anilide*, m. 173°. *dl- β - $C_{10}H_7OCH_2CH_2CO_2H$* (III), m. 108°, was prepd. in a similar manner. *Et ester*, m. 52°; *amide*, m. 169°. The action of the Na salts of 2 and 4-mitronaphthol on II did not give the nitro derivs. of I except in minute quantities. 1,2- and 1,4- $C_{10}H_6(OH)NO_2$ were prepd. by acetylating α - $C_{10}H_7NH_2$ to the naphthalide, m. 159°, and nitrating in AcOH solu. at 0° with fuming HNO_3 . The product was boiled with dil. NaOH and the solu. acidified with HCl and treated with abs. EtOH, pptg. 1,2- $C_{10}H_6(OH)NO_2$, m. 128°, in 25% yield. 1,4- $C_{10}H_6(OH)NO_2$, m. 164°, was pptd. by diln. with H_2O in 50% yield. I cannot be nitrated by HNO_3 and H_2SO_4 , but from AcOH and the calcd. amt. of HNO_3 is obtained 70% 4-nitro-1-naphthoxymethylacetic acid (IV), m. 174°. No isomeric acid could be produced by variation of the conditions. *Me ester*, from MeOH and the acid chloride, m. 98°. *Et ester*, m. 60°; *amide*, m. 201–2°; *acetanilide*, m. 186°. Reduction of IV with Sn and HCl gave 4-amino-1-naphthoxymethylacetic acid, m. 248–50° (decompn.). The 1-nitro deriv. of II was obtained both by direct nitration (65% yield) and by the action of the Na salt of 1,2- $C_{10}H_6(NO_2)OH$ upon $MeCHBrCO_2Et$ (60% yield). 1-Nitro-2-naphthoxymethylacetic acid (V), m. 193°; *Et ester*, m. 83°; *Me ester*, m. 74°; *amide*, m. 157°; *anilide*, m. 171°. Reduction of the acid, esters, or amide leads to naphtho- α -methyl- β -morpholine, $C_{10}H_6NHCOCHMeO$, m. 175.6°. I was resolved

into its optical isomers by means of its compds. with cinchonine, and their soly. differences. *Cinchonine salt*, $[\alpha]_D^{20} = +46.66^\circ$. The free acids, $[\alpha]_D^{30} = +10^\circ$, m. 126° (*dl-mixt.* 152–3°); *acid d-chloride*, $[\alpha]_D^{20} = 120^\circ$; *amides*, $[\alpha]_D^{20} = +46.66^\circ$ in 192°; *dl-mixt.* of amides, m. 151.2°; *anilides*, $[\alpha]_D^{20} = +150^\circ$, m. 205°; *mixt.*, m. 171°. II was also resolved with cinchonine though the salts crystallize less well. After two crystals of the

salts, the acids $[\alpha]_D^{20} = 93.33^\circ$, m. 117° ; their mixt. m. 108° ; *l*-chloride $[\alpha]_D^{20} = -45.33^\circ$; *Et* esters, $[\alpha]_D^{20} = 46.66^\circ$, m. $43-4^\circ$; mixt. m. $52-3^\circ$; *amides*, $[\alpha]_D^{20} = 46.66^\circ$, m. 197° ; mixt. m. 169° . Nitration of the *d*- and *l*-acids obtained from **I** gave acids corresponding to **IV** with $[\alpha]_D^{20} = 46.66^\circ$, m. $141-2^\circ$; mixt. m. 174° ; *d*-chloride, $[\alpha]_D^{20} = 111^\circ$; *Et* esters, $[\alpha]_D^{20} = 46.66^\circ$, m. 55° ; mixt. m. 60° ; *amides*, $[\alpha]_D^{20} = 46.66^\circ$, m. 225° ; mixt. m. $201-2^\circ$; *anilides*, $[\alpha]_D^{20} = 83.33^\circ$, m. 215° ; mixt. m. 186° . In nitrating the active isomers from **III** the sign was changed, $[\alpha]_D^{20} = 123.33^\circ$, m. 179° ; mixt. m. 193° . Derivs. of these undergo no further change of sign. *d*-Chloride, $[\alpha]_D^{20} = 150^\circ$; *Et* esters, $[\alpha]_D^{20} = 123.33^\circ$, m. 102° ; mixt. m. 83° ; *amides*, $[\alpha]_D^{20} = 46.66^\circ$, m. 190° ; mixt. m. 157° ; *anilides*, $[\alpha]_D^{20} = 123.33^\circ$, m. 205° ; mixt. m. 171° . The relations of these acids and derivs. are expressed in the following tables:

There are some unexpected agreements in magnitude of sign. Thus, active **I**, and its amide, active **IV**, its *Et* ester, its amide, the *Et* ester and the amide of **III** and the amide of **V** all have the rotation $\pm 46.66^\circ$. Active **II** has exactly twice this value or $\pm 93.33^\circ$. Active **V**, its *Et* ester and its anilide have the value $\pm 123.33^\circ$. M. A. YOUTZ.

Present-day processes for the commercial synthesis of camphor. J. DUBOURG. *Technique moderne* 18, 170-2(1926).—Review. A. PAPINEAU-COUTURE.

New preparation of α -indanonone. CH. COURTOT AND JAN KROLIKOWSKI. *Compt. rend.* 182, 320-3(1926).—The new method is much simpler and more economical than any previous one (cf. *Ber.* 22, 2019(1889); Weissgerber, *C. A.* 5, 3064; *Ann.* 275, 348(1893); *J. Chem. Soc.* 65, 484(1894)). α -Chloroindanone is oxidized directly to α -indanonone in a similar way to the expts. of Grimaux and Lauth (*Compt. rend.* 54, 572(1877)) on the prepn. of aldehydes. With 50% H_2SO_4 and 50% $\text{Na}_2\text{Cr}_2\text{O}_7$ (1 atom of O per mol. of α -chloroindanone) at $55-7^\circ$, a 90-5% yield of α -indanonone was obtained. The method becomes of potential economic value by the chlorination and oxidation of crude indene from the rectification of tar oils with their phenols removed by treatment with NaOH and their bases removed by washing with dil. acid. These oils contain 56-62% indene. They are satd. at 0° with dry HCl and excess HCl is removed *in vacuo* (10-5 mm.) at $40-50^\circ$. The increase of wt. gives the HCl fixed by the indene and indicates the amt. of oxidizing agent to be used. The yield of α -indanonone is approx. 75%, and this may be increased by eliminating, before oxidation, products which accompany the indene and which distil *in vacuo* before the α -chloroindanone. Since phenolic oils from the tar of coke manuf. contain about 10% indene, α -indanonone becomes a readily accessible product of potential value in the lab. and in industry. C. C. DAVIS.

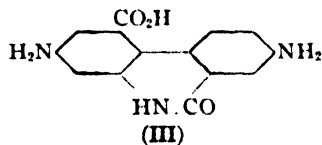

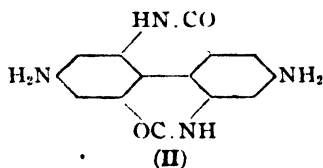

2,7-Naphthalenedicarboxylic acid and its derivatives. ATTILIO PURGOTTI. *Ann. r. scuola agr. Portici* [2] 17, 1-19(1922).—2,7- $\text{C}_{10}\text{H}_6(\text{SO}_3\text{Na})_2$ (10 g.) after drying several hrs. at $230-240^\circ$, was distd. with 15 g. KCN , giving 18% yield 2,7- $\text{C}_{10}\text{H}_6(\text{CN})_2$ as a yellowish, cryst. mass, m. 261° (cor.). Boiled with a soln. of 3 parts of H_2SO_4 in 2 of H_2O for 0.5 hr., 5 g. crude nitrile yielded 5.10 g. of 2,7- $\text{C}_{10}\text{H}_6(\text{CO}_2\text{H})_2$. The yields on boiling with KOH for 5 hrs. and with concd. HCl for 5 hrs. were only 2.7 and 1.2 g.

resp. The product, after pptn. from NH_4OH with cold HCl , does not m. 190° , sublimes with difficulty, carbonizes at 300° , forming C_{10}H_8 . The Me ester, $\text{C}_{10}\text{H}_6(\text{CO}_2\text{CH}_3)_2$, obtained by the action of dry HCl gas on a suspension of the acid in slightly heated MeOH , leaving the satd. HCl soln. several days in a closed vessel, m. 191° (cor.). The Et ester, obtained similarly, m. 238° (cor.). The K salt, obtained by satn. of the crude acid with KOH , cryst. mass contg. $2.5 \text{ H}_2\text{O}$, which is lost at about 180° . The NH_4 salt is an amorphous, dirty white mass, easily decompd. The Ag salt forms a white, flocculent ppt., slightly sol. in H_2O , blackens rapidly when dried, even in the dark. The Ca and Ba salts are brown masses easily decompd by heat. $2,7\text{-C}_{10}\text{H}_6(\text{COCl})_2$, obtained by the action of 2 mols. PCl_5 on 1 mol. of the acid in the presence of POCl_3 finally at 130° , decomp. on distn., reacts easily with NH_3 and PhNH_2 . Passing gaseous NH_3 through a soln. of the chloride in CCl_4 causes vigorous reaction and pptn. of an amorphous yellowish solid. On filtering, drying, dissolving in hot alc. and pptg. with cold H_2O , a yellowish white substance is obtained, sol. in almost all the common solvents but always amorphous. The m. p. varies from 235° to 250° . Subjecting this mixt. of amide and nitrile to distn., a white mass is obtained which cryst. from alc., CHCl_3 and AcOH and is the pure nitrile. PhNH_2 forms the anilide, $2,7\text{-C}_{10}\text{H}_6(\text{CONHPh})_2$, which is nearly insol. in all the common solvents, does not fuse even at 280° and is sol. in PhNH_2 only. $2,7\text{-C}_{10}\text{H}_6(\text{CO}_2\text{Ph})_2$, obtained through the action of dry HCl on a hot mixt. of the chloride and PhOH in excess, and slow cooling, m. 162° (cor.). Impure $2,7\text{-C}_{10}\text{H}_6(\text{COCN})_2$, was formed by heating 3 g. of $\text{C}_{10}\text{H}_6(\text{CO}_2\text{H})_2$ with 6.25 g. of $\text{Hg}(\text{CN})_2$ in the presence of a little CCl_4 in a closed tube for 10 hrs. at 100° , yellowish powder, cannot be purified because it is insol. in the cold and decomp. on heating with formation of the di- CO_2H acid. It was saponif. by Boessneck's method changing, after 10 days, completely into an acid which partly ppts, m. above 280° , is ketonic in character and probably has the formula $\text{C}_{10}\text{H}_6(\text{COC}(=\text{O})\text{H})_2$, is very sol. in all the more common solvents but easily decompd. by heat even in soln. Upon treatment of its di- NH_4 salt in soln. with $\text{NH}_4\text{OH}.\text{HCl}$ a white ppt. forms which contains N after its treatment with AcOH to remove the NH_3 . A similar white ppt., which also contains N after treatment with dil. HCl and washing with alc., is formed with $\text{PhNHNH}.\text{HCl}$. A dinitronaphthalene-2,7-dicarboxylic acid is formed by heating the $\text{C}_{10}\text{H}_6(\text{CO}_2\text{H})_2$ on the water bath with an excess of fuming HNO_3 , cooling, pouring into H_2O , extg. with Et_2O and evapg. the ext. The purified product is very sol. in H_2O and all the common solvents. Alkalies, especially NH_3 , dissolve it with a beautiful dark red color. It intumesces when heated without fusing sharply. The neutral soln. of its NH_4 salt gives with concd. AgNO_3 , a yellow ppt., but slightly sol. in H_2O and darkening on drying. Its Me ester, obtained by passing a current of dry HCl through a soln. of the acid in MeOH , a yellowish, amorphous powder, commences to soften 220° and completely m. 252° . Trinitronaphthalene-2,7-dicarboxylic acid, formed by introducing 4 g. of the $\text{C}_{10}\text{H}_6(\text{CO}_2\text{H})_2$ in finely powd. form in small portions into 30 g. concd. HNO_3 , and 45 g. fuming H_2SO_4 , and heating some time on the water bath, yellowish, amorphous powder which dissolves in alkalies giving an intense dark red color, does not melt even at above 300° but darkens even at lower temp. When heated on Pt foil it burns without explosion. The Ag salt forms an amorphous brown mass which gives a slight explosion when heated rapidly. The Ba salt is formed by heating the acid in suspension in H_2O with pptd. BaCO_3 , yellow mamillary forms or lustrous reddish plates. The Me ester, obtained by the action of gaseous HCl on a MeOH soln. of the acid and letting stand for 12 hrs., begins to m. 243° (decompn.) and at 250° fusion is complete, the mass assuming a black color which persists on recooling. The $2,7\text{-C}_{10}\text{H}_6(\text{CO}_2\text{H})_2$ is distinguished from the acid of Ebert and Merz (*Ber.* 9, 606(1876)) by oxidation with KMnO_4 which gives, instead of phthalic acid, trimellitic acid. A. R. MERZ.

Behavior of some hydrindones towards phenylhydrazine. HERMANN LEUCHS AND GEORG KOWALSKI. *Ber.* 58B, 2822-7(1925); cf. *C. A.* 20, 191. The long pmsms of α -hydrindone obtained by steam distn. contain much H_2O (26.3%). The oxime, m. 146° , undergoes no rearrangement when heated with AcCl in a sealed tube at 95° , merely giving the acetate, m. 85° . Heated with PhNHNH_2 (even in large amt and at $155-60^\circ$), it gives only the phenylhydrazone, for which m. ps. ranging from 120° to 131° are given in the literature; usually it m. brown $124-8^\circ$, after digestion with MeOH $131-3^\circ$, on recrystn. again $124-8^\circ$, in evacuated tubes $134-5^\circ$ without decompn. The deviations are due to impurities produced by soln. and by fusing in open tubes, not to change into structural or spatial isomers; neither could any such rearrangement be produced by treatment in hot MeOH with $\text{H}_2\text{S}_2\text{SO}_4$ or 5% HCl . The α -benzyleneindole, produced by boiling the phenylhydrazone with HCl , m. 254° (previously sintering and turning brown), $254-5^\circ$ without discoloration in evacuated tubes; it reacts neither

with PhNHNH_2 after 7 hrs. at 150° nor with Ac_2O and NaOAc at 100° ; 5 hrs.' boiling with Ac_2O - NaOAc gives an *Ac deriv.*, $\text{C}_{17}\text{H}_{13}\text{ON}$, m. 130° , sol. in about 40 parts hot alc. *2-Ethyl-1-hydrindone*, obtained in 65-75% yield from $\text{PhCH}_2\text{CHClCOCl}$ and AlCl_3 in petroleum ether on the H_2O bath, faintly yellow, b_{18} 144° , has an aromatic odor; *semicarbazone*, m. $200-3^\circ$; no oxime could be obtained; *phenylhydrazone*, does not cryst. and yields no definite products with PhNHNH_2 at 130° ; *p-bromophenylhydrazone*, m. 82° , stable in the air for quite a long time but finally becomes smeary; *2-Br deriv.*, m. $45-6^\circ$. Bishydrindone-2,2'-spiran (2 g.) heated 3-7 hrs. at 130° with 8 g. PhNHNH_2 gives, besides 1.4 g. of the known diphenylhydrazone, m. 102° , 1.5 g. of a more difficultly sol. isomer (I), m. $220-2^\circ$, mol. wt. in 1.63-2.27% C_6H_6 soln. 416, gives a green color with FeCl_3 in H_2SO_4 . There is also obtained 0.1 g. of β -[benzyl-*o*-carboxylic]- α -hydrindone phenylhydrazide (II), $\text{C}_{33}\text{H}_{29}\text{O}_2\text{N}_2$, m. around 238° (decompn.), insol. in dil. alkalies, gives a red-violet color with FeCl_3 - H_2SO_4 , identical with the product obtained from the acid chloride. The acid with PhNHNH_2 at 130° gives only equal parts of I and II. **Addenda to the papers on α -hydrindone- β -oxalic ester (with Georg Kowalski) and anthroxanic acid.** HERMANN LEUCHS. *Ibid* 2827; cf. *C. A.* 20, 179, 1077.—It had escaped the attention of L. and K. that Ruhemann (*C. A.* 7, 1357) had already prepd. hydrindone-oxalic ester; in general, their results agree with those of R., except that the pyrazole-like anhydride, $\text{C}_{10}\text{H}_6\text{O}_2\text{N}_2$, which they obtained from the new isomeric phenylhydrazone of the ester m. $126-7^\circ$, while for that obtained directly from the ester, R. gives $117-8^\circ$. v. Auwers (*C. A.* 18, 2158) from a spectrochem. study of anthroxanic acid in the form of its Et ester derived for it the same formula as did L. from his cleavage expts. *C. A. R.*

Molecular configurations of polynuclear aromatic compounds. V. The identity of the nitration products derived from 2,7- and 4,5-dinitrophenanthraquinones. G. H. CHRISTIE AND JAMES KENNER. *J. Chem. Soc.* 1926, 470-6; cf. *C. A.* 17, 2282.—The nitration of 4,5-dinitrophenanthraquinone gives the 2,4,7-trinitro deriv., previously obtained from the 2,7-dinitro deriv.; the *quinoxaline deriv.*, m. 307° . Oxidation gives 4,6,4'-trinitrodiphenic acid (I), m. 292° , the *quinine d-salt* of which m. 222.5° , $[\alpha]_D^{20} -156.1^\circ$, and the *l-salt*, m. 176° (decompn.), $[\alpha]_D^{19} -77.5^\circ$; the *quinidine l-salt* has $[\alpha]_D^{20} 85.55^\circ$ (56.04° previously given). In passing from the acid to the Na salt, there is a change in sign, so that the prefixes *d*- and *l*- as used in the previous paper should be interchanged. Reduction of 4,6,4',6'-tetranitrodiphenic acid gives a *phenanthridone deriv.* (II), the neutral H_2SO_4 salt, yellow, turning green on exposure to light and air, blackens at 300° , and a *basic salt*, green, being analyzed. Reduction of I gives III, whose H_2SO_4 salt is yellow, turning green on exposure to the air. Dinitrobenzil on further nitration gives the 3,5,3',5'-tetranitro deriv., yellow, m. 168° , whose *quinoxaline deriv.*, m. 274° . Its constitution was established by oxidizing it to 3,5-(O_2N) $\text{C}_6\text{H}_4\text{CO}_2\text{H}$

Esters of furoic acid. J. E. ZANETTI AND C. O. BECKMANN. *J. Am. Chem. Soc.* 48, 1067-9 (1926).—The following esters of *furoic acid* are reported: *Bu*, b_1 83.4° , d_4^{20} 1.0555; *sec-Bu*, b_1 67.9° , d_4^{20} 1.0465; *Am*, b_1 95.7° , d_4^{20} 1.0335; *sec-Am*, b_1 75.7° , d_4^{20} 1.039; *hexyl*, b_1 105.7° , d_4^{20} 1.0170; *sec-hexyl*, b_1 86.8° , d_4^{20} 1.012; *heptyl*, b_1 116.7° , d_4^{20} 1.0005; *octyl*, b_1 126.7° , d_4^{20} 0.9885, does not solidify at -14° . The esters decompose on standing, largely as a result of oxidation; they are stable towards H_2O ; the lower members are readily hydrolyzed by aq. KOH but the higher ones require EtOH KOH . *C. J. WEST*

Synthesis of 2,4-dimethyl-5-carbethoxy-3-vinylpyrrole and its conversion into cryptopyrrole. HANS FISCHER AND BRUNO WALACH. *Ber.* 58B, 2818-22 (1925). *2,4-Dimethyl-5-carbethoxypyrrole-3-carboxylic acid* (I), obtained in 70-95% yield from the di-Et ester added to concd. H_2SO_4 at such a rate that the temp. does not rise above 40° and kept at this temp. 20 min. and then poured upon ice, m. 273° , has a double mol. wt. (424) in camphor (Rast), sublimes without decompn. *in vacuo* on rapid heating easily loses CO_2 under atm. pressure, giving up to 70% 2,4-dimethyl-5-carbethoxypyrrole

(II). 2,4-Dimethyl-5-carbethoxypyrrole-3-acrylic acid (III), obtained almost quant. from the 3-CHO deriv. of II heated with $\text{CH}_2(\text{CO}_2\text{H})_2$ and piperidine until the evolution of CO_2 ceased, m. 240° (decompn.), mol. wt. (Rast) 258 (in the same way were obtained 2,4,5-trimethyl- and 2,4-dimethyl-5-ethylpyrrole-3-acrylic acid, m. 203° and 205° , resp.). 2,4-Dimethyl-3-vinyl-5-carbethoxypyrrole, from III heated in 1-g. portions under 12.5 mm. up to 220° in the course of 6–7 hrs. (yield, about 70%), m. 112° , gives a negative Ehrlich reaction in the cold, positive (blue color) on heating, refluxed with alc. NaOH it yields the hygroscopic 5-carboxylic acid (IV), m. $101\text{--}2^\circ$, while in MeOH with H and Pt sponge it gives the 3-Et compd. (carbethoxycryptopyrrole), m. 91° , identical with the product obtained from cryptopyrrole (V) by the Grignard method. IV, reduced in MeOH with H and Pt sponge and distd. with steam gives V (isolated as the picrate, m. 135°) almost quant. With HI of varying concns. IV loses the vinyl residue, giving 2,4-dimethylpyrrole; mineral acids resinify it, concd. AcOH-HBr carbonizes it and very dil. acid polymerizes or condenses it.

C A R

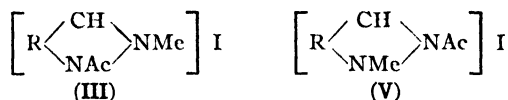

Action of pyridine and bromocyanogen on some pyrroles. HANS FISCHER AND PAUL ERNST. *Ber.* 59B, 138–44 (1926); cf. C. A. 8, 1580. The compd. previously prepd. from 2,4-dimethyl-3-acetylpyrrole (I) with $\text{C}_5\text{H}_5\text{N}$ and BrCN can be obtained in absolutely colorless form by repeated crystn. from alc., it m. 218° (decompn.) (instead of 208°), has the compn. $\text{C}_{27}\text{H}_{30}\text{O}_2\text{N}_6$, contains 2 mols. I (as shown by hydrolysis with concd. HCl and by formation of the 5-Br deriv., decomp. $167\text{--}9^\circ$, of I with Br in AcOH), 2 mols. $\text{C}_5\text{H}_5\text{N}$ (detd. by the method of Malatesta and Germann, C. A. 9, 1020), 2 atoms of N which are given off as NH_3 on hydrolysis and 2 active H atoms (Zerevitinov method). By the direct action of BrCN and $\text{C}_5\text{H}_5\text{N}$ on I in the presence of halogen acids is obtained a blue dye not further investigated. The 2 tetrasubstituted pyrroles (2,4-dimethyl-3,5-dicarbethoxy, 2,4-dimethyl-3-acetyl-5-carbethoxy) subjected to the same treatment were recovered unchanged. Of the trisubstituted derivs. only 2,4-dimethyl-3-carbethoxypyrrole (II) gave a cryst. compd. (III), yellow leaflets, m. 151° , but its compn. ($\text{C}_{20}\text{H}_{24}\text{O}_4\text{N}_4$, mol. wt. in boiling alc. 365 , EtO content 7.97% , active H 0.50%) shows that it contains only one II group and furthermore an HO group, with concd. HCl it gives 1 mol. II, $\text{C}_5\text{H}_5\text{N}$, NH_3 and a substance giving an exceedingly intense red color with $\text{Fe}(\text{NH}_4)(\text{SO}_4)_2$ and oxidized by Br , in the presence of HCO_2H is formed bis-[2,4-dimethyl-3-carbethoxypyrrolyl]methene- HCl . Treated in alc. with concd. HCl and boiled a short time, III evolves ClCN and yields a dye, sepg. from AcOH-HCl in blue-green needles, decomp. $190\text{--}4^\circ$, dil. solns. of which in alc., Me_2CO or AcOEt change after some time from blue-green to red, HCl restoring the blue color, the blue solns. show strong end absorption in the red to 610μ , with a diffuse band between 580 and 553μ . The compn. of the dye (air-dry, C 59.27 , H 6.45 , N 6.30 , Cl 14.12% , dried *in vacuo* at 100° (loss in wt. 8.71%), C 60.27 , H 7.53 , N 6.84 , Cl 8.80) indicates that it is a di- HCl salt of a condensation product of 2 mols. II with 1 mol. glutacetaldehyde and hence belongs to the class of König's polymethine dyes (Schreckenbach, *Diss. Dresden*, 1910). Similarly, from III in alc. with concd. HBr or from II in a little alc. with $\text{C}_5\text{H}_5\text{N}$ and BrCN in Et_2O is obtained a dye, blue needles, decomp. $220\text{--}5^\circ$, with C 54.09 , H 6.29 , N 6.28 , Br 18.50% ; attempts to prep. the free base from this HBr salt with NH_3 in alc. gave a non-cryst. product (C 53.07 , H 7.22 , N 7.54%), begins to smelt 120° but does not m. 220° ; its red soln. in alc. shows strong end absorption in the red but lacks the green band; with concd. HCl in alc. and with HBr it gives the above HCl and HBr salts; the perchlorate (C 52.43 , H 6.17 , N 5.83 , Cl 5.06%), seps. in needles, decomp. above 300° explosively in the air. König has in the meantime prepd. the above HCl salt (C. A. 19, 3488).

C A R

Proline. EMIL ABDERHALDEN AND HANS SICKEL. *Z. physiol. Chem.* 152, 95–100 (1926).—The HCl salt of proline Et ester is quite stable in H_2O and *in vacuo* at 120° whereas the free ester undergoes hydrolysis in the presence of H_2O at ordinary temp. and shows little tendency to form a polypeptide or an anhydride. However, the filtrate obtained in removing EtOH and HCl from the ester- HCl prepd. by hydrolysis of gelatin consists of two layers which, when mixed, evolve EtCl probably with formation of free proline. Proline Et ester b.p. $78\text{--}9^\circ$. In anhyd. Et_2O it undergoes hydrolysis from atm. moisture, with sepn. of proline crystals. From the residue obtained by vac.

A. W. DEX

the stable 2-Ac deriv.; at 50° I and AcI give a very hygroscopic product, m. 83–91°, converted by H₂O into a brown oil, sepd. by means of 2 N H₂SO₄ into II and I; these are also obtained by distg. the original condensation product under 15 mm.; at room temp., I and AcI yielded a product m. 82–90°, sol. in a little cold H₂O and recovered in great part unchanged on evapn. over P₂O₅, but on boiling with H₂O an intense odor of AcOH developed and on evapn. there remained a red-brown mass consisting chiefly of I with a little II; decompn. of the condensation product with K₂CO₃ yielded I and distn. under 15 mm. gave I, II and much indazole. These results indicate that the condensation product has the structure III and that II is 1-acetylintazole; a substance having the same properties is obtained by condensing II with MeI at 50°, while the compd. (IV), m. 170°, formerly regarded as 1-acetylintazole, reacts in an entirely different way with MeI (C. A. 19, 509) (at 100°, II and MeI give a product much contaminated with periodides, at room temp. there is no appreciable reaction in 2.5 months). 1-Methylindazole (IV) and AcI at 100° and at 50° yield products (probably V), m. 95–6° after digestion with Et₂O, at room temp. a product m. originally 125–32° but also m. abt 95° after standing a day in a desiccator; all 3 are somewhat less hygroscopic than III, give AcOH and IV when rubbed with H₂O and are practically unchanged by distn. under 15 mm. Unfortunately, V could not be synthesized from (the labile) 2-acetylintazole, m. 106°, and MeI, as high temps. could not be used and no reaction occurs at room temp.

C. A. R.

Indazylaliphatic acids. K. v. AUWERS AND H. G. ALLARDY. *Ber.* 59B, 95–100 (1926).—Indazole (I) with BrCH₂CO₂Et or MeCHBrCO₂Et at 100–20° gives almost exclusively 2-derivs.; at higher temps. the 1-isomers also are formed and may even become the chief products; in the presence of alkalis both forms are produced. These indazylaliphatic esters are more strongly basic than the indazyl-1-carboxylic esters, they not only form salts with mineral acids (which are decompd. by H₂O) but also picrates; the free acids can readily be obtained by sapon. of the esters, can be recrystd. from H₂O and melt very high; above their m. ps. they lose CO₂ and give the corresponding alkylindazoles, the 2- undergoing this decompn. more easily and smoothly than the 1-isomers. From I and Me₂CBrCO₂Et, which react only at 140°, is obtained 2-ethylindazole (II); probably the HBr formed sapons. part of ester at the high temp. and the resulting EtBr reacts with the unchanged I; the reaction is not smooth and the yield of II is only moderate (3.5 g. from 10 g. I). BrCH₂CH₂CO₂H at a high temp. gives a β-indazylpropionic acid (III) which, in the vacuum of a H₂O pump at 200°, decomp. smoothly into I and acrylic acid. *Indazyl-1-acetic acid*, m. 185–6°. *Et indazyl-2-acetate*, m. 54–4.5°, b₁₁ 175–7° (*picrate*, m. 164.5°); *free acid*, m. 257° (decompn.), forms 1,2-dimethylindazolium iodide with MeI. *Et α-[indazyl-2]-propionate*, yellowish, b₁₁ 172°, sol. in concd. HCl and repptd. by H₂O (*picrate*, yellow, m. 141–2°); *free acid*, m. 209° (decompn.). *1-Ester*, yellowish, b₁₁ 153–5°; *free acid*; *Ag salt*, amorphous powder. II (cf. C. A. 19, 3091), m. 40–1°, b₁₂ 133–4°, d₄²⁰ 1.076, n_D²⁰ 1.591. III, m. 148–9°, sol. in mineral acids and alkalis; *picrate*, yellow, m. 170°.

C. A. R.

Acylindazoles. JAKOB MEISENHEIMER AND OTTO SENN. *Ber.* 59B, 199–202 (1926).—It has been shown (C. A. 19, 508) that 4,5-benzo-7-methyl[hept-1,2,6-oxdiazine] (I) (formerly regarded as 1-acetylintazole) with BzO₂H easily takes up 1 atom of O, the H in position 3 being oxidized to HO. The 3-Me deriv. (II) of I, in which the 3-H atom is replaced by Me, would not be expected to undergo similar oxidation and as a matter of fact it proved to be very resistant towards BzO₂H; even after standing a day with a 2-fold excess of BzO₂H a considerable part of it was recovered unchanged and from the oxidation products were isolated an oil of strong odor (probably methylanthranil) and a small amt. of a substance m. 105–6°, presumably identical with that. m. 114–5°, obtained by oxidation of o-AcNHC₆H₄COMe (III) (Bamberger and Elger. *Ber.* 36, 3650(1903)). On the other hand, II is readily attacked by KMnO₄, yielding chiefly III. 2-Chlorobenzaldehyde benzoylhydrazone, m. 192°, is unchanged by long boiling with aq. or alc. alkalis, dissolves in concd. H₂SO₄ with dark color (H₂O pptg. a yellow substance, m. 142°, probably (2-ClC₆H₄CH:N)₂), rapidly darkens when boiled in cymene with KI, K₂CO₃ and *Naturkupper C* (IV) and yields long red-brown needles, m. about 240° (decompn.). 2-Chloro-5-nitrobenzaldehyde benzoylhydrazone, m. 135–8°, is entirely stable towards alkalis; 0.5 g. in 50 cc. cymene boiled 1.5 hrs. with 1.5 g. ignited K₂CO₃, 0.2–0.3 g. IV and 0.1 g. KI gives 0.2–0.25 g. 1-benzoyl-4-nitroindazole,

m. 192–3°. This synthesis of 1-acylindazoles is a new proof that the compds. formerly regarded as "1-acylindazoles" have the Bischler heptadiazine structure C. A. R.

Comparison of heterocyclic systems with benzene. I. 6,7-Indazolequinone-4-sulfonic acid. L. F. FIESER. *J. Am. Chem. Soc.* **48**, 1097–107 (1926).—6 Amino-indazole is obtained in 83.6% yields by reducing the NO₂ deriv. by SnCl₂; the diazo soln., contg. 1.5 mol. equivs. of H₂BO₃, boiled 15 min. gives 74% of the 6 HO deriv. With PhNH₂Cl this gives 6-hydroxy-7-benzencazoindazole, bright red, m. 238°. Reduction with Na₂S₂O₄ in alk. soln. gives 6-hydroxy-7-aminoindazole, darkens about 190°, decomp. 260°, isolated in 68% yield as the di-HCl salt, microneedles, HCl salt, pale yellow needles with 1 H₂O. It is oxidized to 6,7-indazolequinone, which gives with NaHSO₃ 6,7-indazolehydroquinol-4-sulfonic acid, turns black at 250°; the alk. soln. is first green but in the air it turns brown, clear red and on addn. of acid, yellow. The Na 6,7-indazolequinone-4-sulfonate, orange-yellow needles, results by oxidizing the above acid with NaNO₂; PhNH₂ gives 4-anilino-6,7-indazolequinone, bright red, m. 360° (decomp.); it is reduced by SnCl₂ or Na₂S₂O₄ to a hydroquinol very sensitive to air oxidation. 6-Amino-7-[p-sulfobenzeneazo]indazole, bright red (98% yield) 6,7-Diamino-indazole-HCl, rose-colored needles (51%); the free base is readily oxidized in the air. With HCO₂H and AcONa it gives 6,7-imidazoindazole (1,2,6,8-imidazoindazole), m. 293°. 6,7-Phenanthrazinoindazole (1,2,3,12-indazophenanthrazine), lemon yellow, m. 364°; the H₂SO₄ soln. is carmine-red. E. m. f. measurements are reported at 25° for 6,7-indazolequinone-4-sulfonic acid and 1,2-naphthoquinone-4-sulfonic acid, the normal reduction potentials of the 2 substances are 0.620 v. and 0.630 v., resp., which indicates a close relationship between the pyrazole and the C₆H₄ ring C. J. WEST

Anhydrides of derivatives of amino acids. C. GRANACHER. *Helvetica Chim. Acta* **8**, 865–73 (1925); cf. C. A. **19**, 2051.—35 g. BzNHCH₂CONHEt (I) and 4–5 parts P₂O₅, mixed to a paste with CHCl₃ and boiled 7–8 hrs. on the H₂O bath, taken up with ice-H₂O, filtered, and the aq. soln. made alk., yield 4–7 g. 2-phenyl-4-[glymethylamidimino]-benzoyl-5-ethyliminooxazoline, EtN C O CPh N CHCPh NCl₂CONHEt (II),

C₂₂H₂₄O₄N₄, golden leaflets, m. 143–4°, the reaction going beyond the initial glyoxaline stage (cf. Karrer and G., C. A. **18**, 2708; **19**, 2051) as follows: PhC. N. CH. C (NEt). O +

PhC(OH):NCH₂CONHEt → II. II is not attacked by alkalis, but heated 5 hrs. on the H₂O bath with 5% HCl, it deposits 2-phenyl-4-benzoyl-5-ethyliminooxazoline (III), PhC. N. CHBz C (NHEt) O, purified by removal of an alkali-sol. impurity by

warming with 2% aq. NaOH on the H₂O bath, pale yellow, m. 112°, very weakly basic, in alc. gives a deep yellow color with KOH, intense green with FeCl₃. II or III, heated 1–2 hrs. on the H₂O bath with 20% HCl, loses its yellow color and deposits α-benzoylhippuric ethylamide (IV), BzNHCHBzCONHEt, m. 197–8°, in alc. gives a deep violet-red color with FeCl₃; heated until clear with 5 parts 5% aq. KOH it yields unchanged IV, insol. in Et₂O, BzOH, and I. In an attempt to synthesize IV BzC (NOH)CO₂Et was reduced according to Gabriel and Posner's method for AcCH(NH₂)CO₂Et (Ber. **27**, 1141 (1894)); the resulting HCl salt, boiled 16 hrs. in PhH with BzCl, gives Et α-benzoylhippurate, BzNHCHBzCO₂Et, m. 128–9°, in alc. gives a red color with FeCl₃; is split to I by EtNH₂, hydrolyzes to BzOH and BzNHCH₂CO₂H when heated with alkalis. M. HEIDELBERGER

Anhydrides of amino acid derivatives. C. GRANACHER, V. SCHELLING, AND E. SCHLATTER. *Helvetica Chim. Acta* **8**, 873–83 (1925).—Since the type RC. N. CH. CO NR'

is of interest as an anhydride of tripeptides attempts at its synthesis were made (cf. also preceding abstr.). With Na and alc. PhC. N. CH₂. CO NH yields the Na salt,

evapd. and boiled 3 hrs. with PhH and MeI this gives 2-phenyl-5-methoxyimidazole instead of the expected 1-Me deriv.; it m. 56–8°, is fairly strongly basic, and heated with 1:1 HCl it gives BzOH, NH₄Cl and MeO₂CCH₂NH₂ HCl. PhC. N. CH. CCl NPh,

treated on the H₂O bath in alc. with Na until no more dissolves, yields after evapn. crystals of 1-benzyl-2,3-diphenylimidazolidine (I), PhCH PhN CH₂ CH₂. NCH₂Ph,

and an oil, phenylbenzylethylenediamine (II), PhNHCH₂CH₂NHCH₂Ph. I, m. 123°, is split by cold dil. HCl to BzH and II. To isolate II the aq. sol. of the reduction mixt. is best heated with HCl, extd. with Et₂O, made alk., and again extd. with Et₂O. II, b₁₁, 214–6°, gradually solidifies; with BzH in alc. it gives I, thus accounting for

the presence of I in the reduction mixt.; *dipicrate*, m. 158–60°; *dipicrolonate*, m. 215–7°. $\text{BzNHCH}_2\text{COCl}$ is best purified by shaking out with dry CHCl_3 to remove PCl_5 and POCl_3 . With 2 mols. PCl_5 in CHCl_3 $\text{BzNHCH}_2\text{CONHCH}_2\text{CO}_2\text{Et}$, heated after the initial reaction until reddish, yields *Et 2-phenyl-5-chloroimidazole-1-acetate*, isolated as the *picrate*, sinters 140°, m. 142°; *amide*, sinters 248°, m. 253°, not changed by Br and aq. alk.; with Br and NaOMe in MeOH it gives the *bromouamide*, sinters 260°, m. 264°. *Acetylglycinethylamide*, m. 144°; *1-ethyl-2-methyl-5-chloroimidazole*, b_{12} 101°, smells like $\text{C}_4\text{H}_5\text{NH}$. *Acetylglycinanilide*, m. 191°; *1-phenyl-2-methyl-5-chloroimidazole* (yield poor), isolated from Et_2O as the *picrate*, m. 176°. *Benzoylglucylleucine ethyl ester*, solidifies on long standing; *ethylamide*, m. 209°; neither yielded isolatable amts. of imidazoles.

M. HEIDELBERGER

Tetrahydro- γ -pyrones. IV. W. BORSCHKE AND R. FRANK. *Ber.* 59B, 237–42 (1926); cf. C. A. 18, 837.—Heptan-4-ol 2,6-oxide (I), b. 190°, m. 46–7°, can be obtained in 80% yield from α, α' -dimethyl- γ -pyrone in H_2O with Pt black and H_2 ; it gives in $\text{C}_6\text{H}_5\text{N}$ with $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ the *p-nitrobenzoate*, m. 96°, and with $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ the *p-toluenesulfonate*, m. 88–9°. *4-Chloroheptane 2,6-oxide* (II), b_{20} 65°, is obtained in 1.2 g. yield (together with 3.3 g. *di[hydroxyheptanoxide] phosphite*, $\text{HOP}(\text{OC}_7\text{H}_{13}\text{O})_2$, b_{20} 197°) from I slowly treated below –2° with PCl_5 and allowed to stand in the cold, and in about 50% yield from I slowly added to PCl_5 under cold low boiling petroleum ether and finally boiled 15 min. With EtMgBr , II gives *heptan-2,6-oxide-4-carboxylic acid*, m. 120° (*amide*, m. 197°; *anilide*, m. 177°), and *4,4'-di-[2,6-oxidoheptyl]*, $(\text{CH}_2\text{CHMe.O.CHMe.CH}_2\text{CH})_2$, m. 104°, isomeric with a compd., m. 80°, ob-

tained by Oppenheim in another way (*Diss. Lausanne, 1924*). With SOCl_2 in $\text{C}_6\text{H}_5\text{N}$, 3.9 g. I gives 0.9 g. of the neutral *sulfite*, $\text{SO}(\text{OC}_7\text{H}_{13}\text{O})_2$, b_{20} 160–70°, m. 76–7°. Heated 4 hrs. in a sealed tube at 110° with 4 parts fuming HCl , I gives 65% of a compd. or const boiling mixt. $\text{C}_{12}\text{H}_{24}\text{OCl}_2$ as an oil of peculiar odor, heavier than H_2O , b_{20} 74°. I (13 g.) added to 50 g. PBr_5 under petroleum ether yields 2.2 g. *4-bromoheptane 2,6-oxide*, b_{12} 70–80°; 6.4 g. of a compd. $\text{C}_{12}\text{H}_{24}\text{OBr}_2$, b_{14} 72–4°; and 3.4 g. of a substance, b_{14} 110°, having the compn. $\text{C}_7\text{H}_7\text{OBr}_3$ of a *dimethyltribromoheptadiene oxide*. With HBr (d 1.78) at 100°, 5 g. I gives 4 g. of a compd. $\text{C}_{12}\text{H}_{24}\text{OBr}_2$, b_{25} 94–9°. *Pentan-3-ol 1,5-oxide* (III) (7.4 g. from 10 g. γ -pyrone in H_2O with Pt black and H_2), b_{12} 84°; *p-nitrobenzoate*, m. 69–70°. *3-Chloropentane 1,5-oxide* (7.3 g. from 10.2 g. III slowly added to PCl_5 and CHCl_3 and cautiously warmed a few min.), b_{12} 46°.

C. A. R.

Preparation of benzodi-(γ -pyrones). GEORG WITTIG. *Ber.* 59B, 116–9 (1926). *Resorcinyl dipropionate* (52 g. from 27 g. $m\text{-C}_6\text{H}_4(\text{OH})_2$ with EtCOCl), b. 297–8°; 10 g. treated at 130° with ZnCl_2 and heated until a rapid rise in the temp. indicates that reaction has set in, gives 6 g. *4,6-dipropionyl-1,3-resorcinol* (I), m. 125–6°, 5 g. of which with Ac_2O and NaOAc at 170° yields 4.8 g. $\alpha, \beta, \alpha', \beta'$ -tetramethyl[benzo-1,6,3,4-di-(γ -pyrone)], m. 271–8°; α, α' -diphenyl- β, β' -dimethyl analog (2.5 g. from 2 g. I with Bz_2O and NaOBz at 200°), m. 261–1.5°. *2,3-Dimethyl-7-hydroxychromone* (30 g. from 40 g. 2,4-($\text{HO})_2\text{C}_6\text{H}_3\text{COEt}$, Ac_2O and NaOAc at 160–70° and subsequent sapon. with boiling 2 N Na_2CO_3), faintly yellowish, m. 257–8°, gives quant. with boiling $(\text{EtCO})_2\text{O}$ and EtCO_2Na the *propionate*, m. 75.5–6.5°, 10 g. of which with AlCl_3 at 120–30° yields 9 g. *2,3-dimethyl-7-hydroxy-8-propionylchromone* (II), m. 161.5–2.0°; this with Ac_2O - NaOAc at 170° gives 95% of $\alpha, \beta, \alpha', \beta'$ -tetramethyl[benzo-1,6,3,2-di-(γ -pyrone)], m. 188–91° and this or II with boiling NaOEt in excess gives 2,6-dipropionyl-1,3-resorcinol, m. 82°.

C. A. R.

"Tervalent" carbon. IV. N-Methylpolyaryldihydropyridyls. (Preliminary communication.) K. ZIEGLER AND F. A. FRIES. *Ber.* 59B, 242–8 (1926); cf. C. A. 29, 383.—From the pentaphenylcyclopentadienyl described in the earlier paper can be theoretically derived, by introduction of a -NMe- group between, say, C atoms 3 and 4, an *N*-methyl dihydropyridyl, a radical which, from the observations made in the cyclopentadiene series, should show little tendency to associate and the possible synthesis of which therefore seemed promising. The most obvious way to prep. such a radical would be the removal of the acid residue from the corresponding *N*-methyl pyridinium salt. 2,4,6-Triphenylpyridine (I) reacts quite rapidly with Me_3SO_4 at 100° to form *N-methyl-2,4,6-triphenylpyridinium Me sulfate* (II) and from this numerous other salts can readily be prepd. These quaternary salts show a great tendency to split off the addendum on heating. Thus the chlorides on slow heating at 100° (even on long heating *in vacuo* at 60–6°) or rapid heating to 122° decomp. into I and MeCl and II suffers the same decompn. at 174°; the aq. solns. of the salts, on the other hand, are perfectly stable on long boiling. 2,3,5,6-Tetraphenylpyridine and pentaphenylpyridine behave in the same way as I. If strips of Zn or Mg are dipped into an aq

soln. of the *N*-methyltriphenylpyridinium chloride (III) the surface of the Zn after some time, that of the Mg immediately, becomes covered with a dark blue layer; on adding an org. solvent immiscible with H₂O and shaking, the drops of the org. liquid, as they rise through the H₂O, assume a red-violet color but are immediately completely decolorized when they reach the surface; if the expt is carried out in a completely filled flask or under N the liquid floating on top of the H₂O soon becomes so intensely red-violet that it becomes completely opaque, but on exposure to the air it is very rapidly and completely decolorized. Of the solvents so far tried, AcOH seems to accelerate most the formation of the colored substance, in petroleum ether the reaction proceeds more slowly but the product is difficultly sol in this medium and seps in apparently amorphous flocks. The same characteristically colored solns., sensitive to air are obtained by the action of PhMgBr on III and on electrolysis of III in H₂O there sep at the cathode the same H₂O-insol blue flocks as are obtained with Mg alone or in the presence of petroleum ether. These methods of formation make it practically certain that the blue substance is *N*-methyl-2,4,6-triphenyldihydropyridyl, and although its isolation in analytically pure form has not yet been effected it can be asserted with considerable certainty that it is a radical which, if not completely monomol., shows very little tendency to associate. II (yield, 75%), seps in crystals with 1 H₂O, m. 101° on rapid heating, resolidifies 109° and m. again 174° (decompn.), acid chloride, C₂₁H₂₀NCl·HCl·2H₂O, m. 118–20°, decomp. 122° on rapid heating, sinters 101° on slow heating, resolidifies 123° and decomp. 143°, neutral chloride, seps with 2.5 H₂O. The solns. of the 2 chlorides remain clear on addn. of dil NaOH but assume a yellowish color; concd. NaOH ppts. a yellow substance, concd. Na₂CO₃ a white substance which is apparently not the carbonate but the "pseudo-base"; KBr, KI, HClO₄, HNO₃ give the corresponding difficultly sol salts; the sulfate is apparently easily, the ZnCl₂ and HgCl₂ double salts are difficultly sol, permanganate, violet-red, decomp. in aq suspension at 100°, deflagrates when heated in dry state on the H₂O bath. C A R

Question of the existence of the simplest monomeric dihydroquinolines. W. KÖNIG AND R. BUCHHEIM *Ber* 58B, 2868 70(1925). K and B confirm the doubts cast by Meisenheimer and Stotz (C A 20, 1082) on Rath's supposed synthesis of 1,2-dihydroquinolines (C A 18, 2707). They were never able to obtain from *o*-MeC₆H₄NH₂ and chloro- or bromoacetal any substance which might be regarded as monomeric dihydroquinoline; the products, obtained in the same amts and with the same b p (about 225–30°) as reported by R., yielded with HNO₃ only very small amts. of nitrosamine-like, easily resinified substances, and always consisted in large part of a diazotizable, i. e. of a primary aromatic amine, b 224–6° (after purification through the Bz deriv., m. 179°), d₄²⁰ 0.96251, n_D²⁰ 1.5491, contg 10.48% N and identified, through the compn. of its Bz deriv. (C 79.8 H 7.60, N 5.86%), and the m p of its Ac deriv. (105°), as 2,4-MeEtC₆H₃NH₂. K and B have also been unable to obtain *N*-ethylindole by R.'s method (C A 18, 2898). C A R

Synthesis of β-arylsulfonylquinolyl-α-arylsulfonylmethanes, their degradation by reduction and acid and the determination of their constitution. J. TROGER AND G. PAHLE, *J. prakt. Chem* 112, 221–42(1926). -- *p*-MeC₆H₄SO₂CH₂COCH₂Br (I) and freshly pptd. AgCl in EtOH give quant the chloride, m 140°; AgI gives the iodide, m 102°. *o*-Anisylsulfonylbromoacetone, m 115°, from the ketone and Br in C₆H₆ at room temp. With *p*-MeC₆H₄SO₂Na or from I and *o*-MeOC₆H₄SO₂Na there results *o*-anisylsulfonyl-*p*-toluenesulfonylacetone, m 177° (phenylhydrazone, yellow, m 113°); *o*-H₂NC₆H₄CHO in a tube at 160° for 1 hr gives β-*o*-anisylsulfonylquinolyl-α-*p*-tolylsulfonylmethane (II), m. 208°. Heating with concd HCl for 1 hrs in a tube gives β-*o*-anisylsulfonylquinolalidine, m. 159°, reduced by Sn and HCl to MeOC₆H₄SH. Reduction of II with concd. HCl and Sn and distn. with steam give a mixt. of MeOC₆H₄SH and MeC₆H₄SH, and after making alk., tetrahydroquinolalidine. *p*-Anisylbromoacetone, m. 104°; the *p*-tolylsulfonyl deriv., m 140°, β-*p*-anisylquinolyl-α-*p*-tolylsulfonylmethane, grayish green, m. 187°. *o*-Phenylsulfonylbromoacetone, m 80°, the *p*-tolylsulfonyl deriv., m. 144° (phenylhydrazone, yellow, amorphous, m 80°) β-*o*-Phenylsulfonylquinolyl-α-*p*-tolylsulfonylmethane, grayish green, m 194°; the constitution was established by degradation by acid and reduction. *p*-Phenylsulfonylbromoacetone, m 108°; the *p*-tolylsulfonyl deriv., m 116°. β-*p*-Phenylsulfonylquinolyl-α-*p*-tolylsulfonylmethane, gray, m. 182°. *o*-Anisylsulfonyldibromoacetone, m 160°, from the ketone and Br in AcOH at room temp. Di-*o*-anisylsulfonylacetone, m 165°, β-*o*-Anisylsulfonylquinolyl-α-*o*-anisylsulfonylmethane, m. 188°. *p*-Bromophenylsulfonylacetone, m 103°; quinolyl-α-*o*-anisylsulfonylmethane, m. 150°. Di-*p*-bromophenylsulfonylacetone, m. 195°, β-*p*-Bromophenylsulfonylquinolyl-α-*p*-bromophenylsulfonylmethane, m. 132°; its constitution follows from the products of its reduction. *p*-Bromophenylsulfonyl-α-anisylsulfonylacetone, m. 160°.

β -*p*-Bromophenylsulfonylquinolyl- α -*o*-anisylsulfonylmethane, m. 191°. *p*-Bromophenylsulfonyl-*p*-tolylsulfonylacetone, m. 163°. β -*p*-Bromophenylsulfonylquinolyl- α -*p*-tolylsulfonylmethane, m. 193°. *p*-Bromophenylsulfonyl- β -naphthylsulfonylacetone, m. 165°. β -*p*-Bromophenylsulfonylquinolyl- α -(β)-naphthylsulfonylmethane, grayish green, amorphous powder, m. 195°.

C. J. WEST

Condensation of γ -methoxyquinaldine with aromatic aldehydes. J. TRÖGER AND E. DUNKER. *J. prakt. Chem.* 112, 196-220(1926); cf. C. A. 19, 1278. γ -Methoxyquinaldine (I) and *p*-MeOC₆H₄CHO, heated with or without ZnCl₂ of K₂SO₄ *in vacuo*, give *p*-methoxybenzylidene- γ -methoxyquinaldine (II), pale yellow, m. 144°; HCl salt, with 2H₂O, yellow needles; methiodide, yellow, m. 168°; ethiodide, golden yellow, sinters 236°, m. 246°. If the above condensation is carried out under pressure at 185-90° there results α -*p*-methoxybenzylidene-*N*-methyl-*py*- γ -ketoquinaldine (III), light yellow, m. 283°; that III is not a polymer of II is indicated from its normal mol. wt. in PhOH. II is transformed into III by passing MeI vapors through molten II. The HCl salt, orange-yellow, m. 144°; ethiodide, yellow, m. 219°. Catalytic reduction of II gives the benzyl deriv., m. 92°; HCl salt, pale yellow, with 1.5 H₂O, III likewise gives a benzyl deriv., m. 214°; HCl salt, m. 197°. α -*o*-Methoxybenzylidene- γ -methoxyquinaldine (IV), yellow, m. 130°, from I and *o*-MeOC₆H₄CHO; HCl salt, citron-yellow, m. 191°. The benzyl deriv., m. 108°; picrate, yellow, m. 176°; this is much more sol. in EtOH than the picrate of IV, yellow, m. 208°. α -*o*-Methoxybenzylidene-*N*-methyl-*py*- γ -ketoquinaldine, yellow, m. 268°. α -*m*-Methoxybenzyl- γ -methoxyquinaldine, m. 49°; chloroplatinate, yellow; picrate, yellow, m. 154°. 3,4-Dimethoxybenzylidenequinaldine, m. 109-10°; the reaction is complete in 2 hrs. at 130°, in 15 min. at 155°. The benzyl deriv., m. 52°; chloroplatinate, orange leaflets. None of these benzyl derivs. is identical with cuspateine.

C. J. WEST

Reduction of β -arylsulfonylquinoline derivatives. J. TRÖGER AND A. UNGAR. *J. prakt. Chem.* 112, 243-67(1926).—*p*-Bromophenylsulfonylacetone, m. 100°; with *o*-H₂NC₆H₄CHQ this gives β -*p*-bromophenylsulfonylquinaldine (I), m. 168°. Reduction of 0.25 g. in 50 cc. fuming HCl by 3 g. Zn (60-75 min., the steam distillate amt. to 5 600 cc.) gives 76.1% (*p*-BrC₆H₄S₂). Under similar conditions β -*p*-chlorophenylsulfonylquinaldine gives 67.8% (*p*-ClC₆H₄S₂); β -*p*-tolylsulfonylquinaldine, 55.2% of (*p*-MeC₆H₄S₂); β -phenylsulfonylquinaldine, 60.2% of (PhS)₂. After removal of the thiophenol, the reaction product, after making alk., gives tetrahydroquinaldine (II), whose HCl salt, m. 195-6°; this is a mixt. of the *bz*- and *py*-derivs., which may be sepd. by fractional crystn. of the *bz*-deriv. The *py*-deriv. gives a HCl salt m. 190° (v. Braun gives 128-30°); the *bz*-deriv. gives a HCl salt m. 164°; a mixt. of the 2 m. 195-6°. β -*p*-Bromophenylsulfonylquinophthalone, light yellow leaves, from I, C₆H₄(CO)₂ and ZnCl₂; reduction gives II and *p*-BrC₆H₄SH. α -Propenyl- β -*p*-bromophenylsulfonylquinoline, m. 173°, in 30% yield from I, paraldehyde and ZnCl₂; HCl salt, m. 132°. The *p*-toluene deriv., m. 165°, on reduction with Sn and HCl yields *p*-MeC₆H₄SH and α -propyltetrahydroquinoline, whose HCl salt m. 216° and *Bz* deriv., m. 97°. Reduction with Pd and H gives α -propyl- β -*p*-tolylsulfonylquinoline, amorphous, further reduced by Sn and HCl to the above products. I and MeI in MeOH give the methiodide, yellow, m. 157°; reduction with Sn and HCl gives 90% of the theory of *p*-BrC₆H₄SH and *N*-methyl- α -methyltetrahydroquinoline. In the reduction there is also formed a small amt. of a base, m. 58°, which may be a decahydroquinaldine, though the amt. was insufficient to identify it completely. The following yields of disulfide were obtained upon reduction of β -arylsulfonyl- α -aminoquinoline: toluene, 73; *p*-chlorobenzene, 75; *p*-bromobenzene, 80; β -naphthalene, 46. α -Amino- β -*p*-tolylsulfonylquinoline-*MeI* yellow, m. 185°; the *p*-bromophenyl deriv., yellow, m. 192°. The corresponding ethiodides, yellow, m. 194° and 204°, resp. On reduction they give the corresponding thiophenol and the substituted II. α -Dimethylamino- β -*p*-tolylsulfonylquinoline, m. 132°, reduction gives nearly quant. *p*-MeC₆H₄SH. α -Dibenzylamino- β -*p*-tolylsulfonylquinoline, pale yellow, m. 164°. The reduction of β -*p*-tolyl- and β -*p*-bromophenylsulfonylcarbo-styryl is discussed.

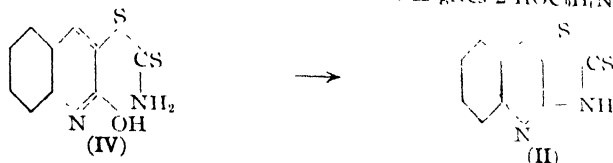

C. J. WEST

Use of rhodanine in organic synthesis. VI. Quinrhodine. C. GRANACHER, A. OFFNER AND A. KLOPPENSTEIN. *Helvetica Chim. Acta* 8, 883-92(1925); cf. G. Mahal, and Gerö, C. A. 18, 2166.—50 g. finely powd. *o*-O₂NC₆H₄CH: C. S. CS. NH. CO

(I) added to a boiling hot soln. of 50 g. Na₂CO₃ in 2 l. H₂O, reduced with a boiling soln. of 350 g. FeSO₄·7H₂O, 600 cc. H₂O, and 150 cc. NH₄OH, heated 15 min. on the H₂O bath, treated with 150 g. Na₂CO₃, filtered, and acidified with dil. HCl, yields 37 g. crude quinrhodine (II), purified by boiling with 20% aq. NaOH, dilg., pptg. with HCl, and crystg. from EtOAc or AmOH; yellow leaflets or brown-red needles, m. 295°. The

intermediate $o\text{-H}_2\text{NC}_6\text{H}_4\text{CH} \begin{smallmatrix} \text{C} \text{ S } \text{CS} \text{NH} \text{CO} \end{smallmatrix}$ (III), pro

rectly to II, since this could not be accomplished by dehydrating agents like Ac_2O , but more plausibly the rhodanine ring is opened by the boiling Na_2CO_3 , after which reduction and condensation take place according to the scheme: $\text{O}_2\text{NC}_6\text{H}_4\text{CH}:\text{C}(\text{CO}_2\text{Na})_2\text{S} \xrightarrow{\text{NH}_2} \text{H}_2\text{NR} \rightarrow \text{IV} \rightarrow \text{II}$. II reacts for SH, does not couple in alk. soln with PhN_2Cl , and forms a K salt (V), yellow needles, oxidized by $\text{K}_2\text{Fe}(\text{CN})_6$ to an insol disulfide. V and PhCH_2Cl , shaken in H_2O 5 hrs, give quinrhodine benzyl thioether, straw yellow, m. 145° . Fused with alkali to a clear melt II gives 2-HOC₆H₄N (VI), added

to 50% aq. NaOH at 120° and stirred 10-15 min., gradually raising the temp. to 180° , it yields mainly 3-sulfhydryl-2-quinolone (VII), with varying amts. of the corresponding disulfide, sol. in alc., and VI. VII is also formed in small amt. on fusing III with alkali. m. 104° . KOH with Me_2SO , it forms 2-quinolone 3-Me thioether, m. 271° (decompn.). benzyl ether (VIII), m. 234° . 1 g. VIII, boiled with excess EtI and treated dropwise with the calc'd amt. 20% NaOH, boiled 15 hrs, neutralized with HOAc, conc'd to incipient turbidity, and boiled with 200-300 cc. H_2O , yield *N*-ethyl-2-quinolone 3-benzyl thioether, white from AcOH, yellowish needles from alc., m. 138° . $\text{MeN} \begin{smallmatrix} \text{C} \text{O} \text{CH} \text{S} \text{CS} \end{smallmatrix}$ condenses smoothly with $o\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$ in HOAc with NaOAc

on the H_2O bath, boiled 15 hrs. with Ac_2O the product gives *N*-methylquinrhodine, pale yellow, m. 205° ; *N*-ethylquinrhodine (IX) sep. from the HOAc reaction mixt., almost white needles from AcO, m. 155° (yield 56%); *N*-phenylquinrhodine, pale yellow plates from AmOH, white from AcO, m. above 285° ; *N*-benzylquinrhodine, yellowish, m. 233° . IX is not attacked by boiling 50% KOH, but when fused with 50% NaOH, raising the temp. during 0.5 hr. to 220° , it yields VII on acidification. $\text{EtN} \begin{smallmatrix} \text{C} \text{O} \text{CH} \text{S} \text{CS} \end{smallmatrix}$

and 3,5-(O.N)₂C₆H₃CHO, boiled in a little HOAc for 2 hrs. give 2,4-dinitrobenzal-*N*-ethylrhodanine, red-brown, m. 133° , reduced with NH_4OH FeSO_4 it yields, on extn. of the Fe oxides with alc., the 2,4-diamino deriv., red violet, m. 223° ; boiled with Ac_2O this gives the diacetamino deriv., yellow brown, m. 272° , instead of a quinrhodine.

M. HEIDELBERGER

Condensations involving reactive methyl groups in heterocyclic bases. J. E. HUMPHRIES, *J. Chem. Soc.* 1926, 3716. Quinaldine and Michler's hydrol (I) in glacial AcOH condense to the pale yellow $\text{C}_{20}\text{H}_{16}\text{N}_2\text{CH}_2\text{CH}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$, m. 131° , oxidation with PbO_2 and AcOH gives a red amorphous dye, whose oxalate, $\text{C}_{20}\text{H}_{16}\text{O}_4\text{N}_4$, was analyzed; it dyes silk violet, while the salts are red the pseudo base is brown. *p*-Toluquinaldine and I give the compd., $\text{C}_{25}\text{H}_{24}\text{N}_4$, m. 152° . α -Picoline and I give the pale yellow compd., $\text{C}_{24}\text{H}_{22}\text{N}_4$, m. 187° . *p*-Toluquinaldine MeI (II) and I give Cu-red needles, $\text{C}_{22}\text{H}_{24}\text{N}_4\text{I}$, m. 160° (decompn.). II and $\text{PhN} \cdot \text{HSO}_3$ in EtOH at room temp. give II peroxide, golden yellow, m. 133° . II and $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ (III) in EtOH at 0° give 2-formyl-6-methylquinoline *p*-nitrophenylhydrazine, reddish brown, m. 211° , identical with the synthetic product from the hydrolysis product of $\text{C}_{10}\text{H}_{11}\text{N}(\text{Me})\text{CH} \cdot \text{NC}_6\text{H}_4\text{NMe}_2$ and $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$. Quinaldine-MeI and III gave the compd., $\text{C}_{17}\text{H}_{16}\text{O}_2\text{N}_4\text{I}$, red, m. 250° . The EtI deriv. gave the compd., $\text{C}_{15}\text{H}_{15}\text{O}_2\text{N}_4\text{I}$, red, m. 262° . α -Picoline MeI gave the compd., $\text{C}_{17}\text{H}_{16}\text{O}_2\text{N}_4\text{I}$, yellow, m. 260° . These compds. are all hydrazones. C. J. WEST

Course of the quinaldine synthesis with tetralylamines. 7,8-Tetramethylenequinaldine. JOSEF LINDNER AND ALFRED SIEGEL, *Monatsh.* 46, 225-49 (1926). Benzoyl- α -tetralylamine, m. 151° . Using the method given in C. A. 18, 2707, α -tetralylamine gives 7,8-tetramethylenequinaldine, m. 55° ; HCl salt, darkens 230° , m. 236° ; HBr salt, darkens 300° , m. $309-10^\circ$; soly. in H_2O , about 25° ; III salt, decomp. about 190° ; soly. in cold H_2O , about 1° . Picrate, yellow, m. 199° , soly. in hot H_2O , about 25° . C. J. WEST

Course of the quinaldine synthesis with β -aminotetralin. II. JOSEF LINDNER AND MAX STAUFER, *Monatsh.* 46, 231-40 (1926), cf. C. A. 18, 2707. This is largely

a theoretical discussion. The sepn. of the 6,7- and 5,6-tetramethylenequinaldine is best carried out by means of the HI salt; the relative yields of the 2 products are 35 and 65%. The 2 picrates have practically the same soly. in hot and cold EtOH. M. p. curves of mixts. contg. 87 to 25% of the 5,6-deriv. show a flat course from 175° to 167°. Dehydrogenation of the 6,7-deriv. gives α' -methyl- α -anthrapyridine (benzolo-6,7-quinaldine), m. 129°, b. *in vacuo* around 210°. HCl salt, darkens 196°, m. 200°; picrate, yellow, m. 216°.

C. J. WEST

Anthraquinone series. I. Amides from substituted anthraquinonecarboxylic acids with aminoanthraquinones. ALEXANDER ROLLET, OSKAR HAIDER AND ALOIS MERKA. *Monatsh.* 46, 131-6 (1926).—1-Chloroanthraquinone-2-carboxyl chloride, yellow, m. 201°; boiled with about 2 mols. 2-aminoanthraquinone in C_6H_6 for 5-8 hrs., there results 75-90% of 1-chloroanthraquinone-2-carboxylic acid-anthraquinone-2-amide (I), pale yellow, m. 317°; concd. H_2SO_4 gives an orange-yellow color. 1-Chloro-2-aminoanthraquinone gives 60-75% of the compd. $C_{28}H_{13}O_5NCl_2$ (II), pale brownish yellow, m. 347°. 1-Aminoanthraquinone gives 95% of the compd. $C_{28}H_{14}O_5NCl$ (III), deep yellow, m. 241°; the red-brown bath dyes cotton brownish red, turning to a pale greenish yellow in the air. The condensation product from 1,5-nitraminoanthraquinone could not be purified. I and 10% NH_4OH in a sealed tube give the 1-amino deriv., red, m. 365°; the brownish red vat dyes cotton the same color, changed in the air to a bluish rose. The corresponding deriv. from II, dark red, m. 368°; from III, $C_{28}H_{16}O_5N_2$, m. 331° (not sharply); the brownish red vat dyes cotton a pure red; because of impurities, the yield averages 55%, the highest being 80%. The by-products, one of which m. 293°, were not examd.

C. J. WEST

Comparison of boldine dimethyl ether with glaucine. KURT WARNAT. *Ber.* 59B, 85-6 (1926); cf. C. A. 20, 1405. The suggested identity of boldine di-Me ether with glaucine has been fully confirmed by direct comparison with a sample of glaucine supplied by Gadamer.

C. A. R.

Tetrahydroacridine, octahydroacridine and their derivatives. II. Resolution of the octahydroacridines (A) and (B). WM. H. PERKIN, JR., AND WM. G. SEDGWICK. *J. Chem. Soc.* 1926, 438-45; cf. C. A. 19, 521.—dl-Octahydroacridine (A) (m. 82°) is resolved by camphorsulfonic acid; the *l*-deriv., m. 85°, $\alpha_D -32^\circ$ (0.5 g. in 20 cc. EtOH); *d*-camphorsulfonate, m. 182°. The *d*-deriv., m. 84.5°, $\alpha_D 34^\circ$ (EtOH, c 2.5), 29° (Me_2CO , c 2.0); *d*-camphorsulfonate, m. 180°. Both active modifications undergo racemization on distn. and when equal amts. are mixed and recrystd. from Et_2O (m. 82.5°). 1-Octahydroacridine (B), m. 73°, $\alpha_D -24^\circ$ (EtOH, c 2.5), -19° (Me_2CO , c 1.0); *d*-camphorsulfonate, m. 172°; the *d*-base, m. 73°; $\alpha_D 22^\circ$ (EtOH, c 2). The salts of the B form are more sol. than those of the A form and the 2 may be sepd. by treatment with *d*-camphorsulfonic acid and crystn. from EtOH. $o-H_2NC_6H_4CHO$ (3 g.) and 1-methylcyclohexan-3-one (5 g.) heated at 100° for 1 hr. and at 130° for 1.5 hrs., give 3 g. 6(or 8)-methyltetrahydroacridine (I), m. 70-71°; picrate, yellow, m. 182°; reduction gives a mixt. of methyltetrahydroacridine (A), m. 92°, of which the *d*- and *l*-forms were prepd., m. 92°, $\alpha_D 20^\circ$ (EtOH, c 0.6) and -28° (EtOH, c 0.5) and the B form, m. 80°. I was also prepd. by heating 6(or 8)-methyltetrahydroacridinecarboxylic acid, yellow, m. 296° (decompn.) (from isatin and 1-methylcyclohexanone in 30% KOH) at its m. p. until the evolution of CO_2 ceased. Only the A form results when 6(or 8)-methyltetrahydroacridone is reduced by Na-Hg.

C. J. WEST

Tautomeric forms of 2,5-diketopiperazines and polypeptides. EMIL ABDERHALDEN AND ERNST SCHWAB. *Z. physiol. Chem.* 152, 88-94 (1926).—From enolized diketopiperazines the corresponding enolic dipeptides may be obtained by opening of the ring. The labile enol form of the anhydride undergoes cleavage much more readily than the stable keto form. In addn. to the isomers contg. double bonds between two pairs of carbons, other isomers representing the half enolized form and also double linkages between C and N are conceivable. By neutralizing an NaOH solution of the enol form of glycine anhydride with HCl and evapg. under diminished pressure, the unsatd. dipeptide was obtained. It decolorized $KMnO_4$ in the cold, gave the xanthoproteic and ninhydrin reactions, and dissolved in NaOH with intense yellow color which disappeared on heating. At 90-100° it rearranged to the keto form. It reacted with CH_3N_3 , but the resulting ether-ester could not be crystd. Enolized leucylglycine was obtained from the corresponding anhydride by hydrolysis and also by heating the ordinary dipeptide at 200° with Ph_3NH . It gave the same reactions as the enolic glycylglycine. A 0.05 *M* soln. was completely hydrolyzed by 0.2 *N* NaOH in 9 hrs. while the satd. form showed no hydrolysis in 15 hrs.

A. W. DOW

Decarboxylation of amino acids with formation of the corresponding amines and the preparation of the enol form of 2,5-diketopiperazines. EMIL ABDERHALDEN AND

Acetic anhydride and acetaldehyde from ethylidene diacetate. M. J. MARSHALL and G. S. SHAW. U. S. 1,578,454, March 30. H_3PO_4 is added to the ethylidene diacetate as a catalyst to facilitate its decompn. by heat.

Butyraldehyde. C. E. PIGG. U. S. 1,576,544, March 16. A mixt. of normal BuOH vapor and H₂O vapor is passed over a dehydrogenating catalyst such as one contg. Cu or brass at a temp. of 200-350° and the vapors are condensed.

Parabutyraldehyde. C. BOGIN. U. S. 1,576,503, March 16. H₂SO₄, ZnCl₂ or other acidic catalyst is added to butyraldehyde and the temp. of the mixt. is maintained at 15-50° until reaction is complete.

Oxalates from tree barks. W. A. FRAYMOUTH. U. S. 1,577,573, March 23. Bark of *Terminalia arjuna* or similar trees is crushed or ground to liberate oxalate crystals and the latter are recovered by froth flotation.

Dialkyl selenides and tellurides. C. A. HOCHWALT. U. S. 1,578,731, March 30. An alkali metal alloy such as one contg. Na and Se or Te is caused to react with a dialkyl sulfate, *e. g.*, R₂SO₄.

Symmetrical disubstituted thioureas. W. FLEMMING. U. S. 1,577,997, March 23. An amine, *e. g.*, aniline, is caused to enter into reaction with such amts. of aq. caustic alkali soln. and of CS₂ that the formation of thioureas and trithiocarbonate can take place simultaneously (equi-mol. proportions of amine, caustic alkali and CS₂ being used).

Benzoic acid. P. SEYDEL. U. S. 1,576,999, March 16. Toluene is oxidized to benzoic acid with 40% HNO₃ under a pressure of 10-80 lbs. per sq. in. in the presence of an oxide of Mn.

Oxidizing nitro aromatic compounds. E. R. MAXTED and B. F. COLE. Brit. 237,688, June 2, 1924. *p*-O₂NC₆H₄Me yields *p*-O₂NC₆H₄CO₂H when put in contact with an over Sn vanadate made by pptg. SnCl₄ with NH₃ vanadate in aq. soln.; *o*-ClC₆H₄Me yields *o*-ClC₆H₄CO₂H, nitronaphthalene produces nitrophthalic acid, nitroanthracene forms anthraquinone and *p*-nitrocinamic acid gives *p*-O₂NC₆H₄CO₂H. Other compds. which may be similarly oxidized include *o*- and *m*-nitrotoluene, nitroxylenol, nitro-mesitylene, nitrodurene, nitroethylbenzene, nitropropylbenzene and the corresponding halogen compds. Vanadates of Bi, Pb and Co also are referred to as suitable catalysts for oxidation of these and similar compds.

Nitroanisoles. E. H. WELTZ. U. S. 1,578,913, March 30. *o*-O₂NC₆H₄Cl is heated to 105-110° with MeOH in the presence also of H₂O and alkali metal hydroxide.

***o*-Benzylphenol.** W. KROPP, W. SCHRANZ and W. SCHULMANN. U. S. 1,580,053, April 6. PhOH is treated first with a benzyl halide and the resulting mixt. is then treated with a soln. of Ba(OH)₂ and heated. The cooled liquid is filtered and *o*-benzylphenol is sep'd from the filtrate by acidulation.

1-Phenyl-2,3-dimethyl-4-dimethylamino-5-pyrazolone. G. LOCHMANN. U. S. 1,580,059, April 6. See Brit. 214,261. C. 1, 18, 2582.

11 - BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A- GENERAL

FRANK P. UNDERHILL

The permeability of protoplasm to ions. MARILDA M. BROOKS. *Am. J. Physiol.* **76**, 116 (1926).—An analysis of the author's data on the amts. of As found by chem. analysis in the protoplasm, sap and wall, resp., of *Lecania* shows that the penetration of As₂O₃ and As₂O₅ cannot be explained according to the hypothesis (advocated by Osterhout) that only undissoc. mols. can penetrate living protoplasm. M. M. B.

Mechanism of the action of proteolytic enzymes. P. GIEARD. *Bull. soc. chim. biol.* **8**, 30-4 (1926). Comment on Hugounenq and Loiseleur. C. 1, 19, 3499. A. T. C.

Primeverose, primeverosides and primeverosidase. M. BRIDEL. *Bull. soc. chim. biol.* **7**, 925-32 (1925). See C. 1, 19, 2514. A. T. CAMERON.

The comparative physiological importance of iron and of zinc. G. BLERAND and H. NAKAMURA. *Bull. soc. chim. biol.* **7**, 933-41 (1925). See C. 1, 19, 3418. A. T. C.

The constitution of proteolytic enzymes and the mechanism of their action. L. HUGOUNENQ and J. LOISELEUR. *Bull. soc. chim. biol.* **7**, 953-73 (1925). See C. 1, 19, 3499. A. T. CAMERON.

The unsaturated mono-ethylenic fatty acids. Physiological role of the ethylene function. E. ANDRÉ. *Bull. soc. chim. biol.* **7**, 974-1003 (1925). A review. A. T. C.

The effect of different hydrogen-ion concentrations on mitochondria in the liver cell. I. T. SCOTT. *Am. J. Anat.* **36**, 385-97 (1925). Mitochondria are best preserved (in physiol. salt soln.) when the pH of the soln. is between 7.5 and 8.6. A. T. CAMERON.

Application of the phenomena of fluorescence in biological chemistry. R. FABRE. *Bull. soc. chim. biol.* 7, 1024-38(1925); cf. *C. A.* 20, 545, 722.—Fluorescence can be used for the qual. and quant. detn. of hydrastine in urine, quinine in urine, salicylic acid in milk after absorption of aspirin, and hematoporphyrin in Harder's gland and in rabbit's bile after intoxication with sulfonal. A. T. CAMERON

Hematoporphyrin. I. Some optical properties of this pigment. Application to the measurement of hematoporphyrin in Harder's gland in the white rat. **II.** Study of the photosensibilizing action of hematoporphyrin on the red corpuscles. R. FABRE AND H. SIMONNET. *Bull. soc. chim. biol.* 8, 56-66(1926); cf. Fabre, *C. A.*, 20, 545, 722, and preceding abstr.—By using the spectrophotometric detn. of the partition of intensity on the fluorescent spectrum, the quantity of hematoporphyrin in Harder's gland in the white rat is per pair of glands of mean wt. 0.18 g. from 1.25 to 1.5×10^{-6} g. The photosensibilizing action appears to be exclusively produced by radiations from the yellow region of the spectrum. A. T. CAMERON

Buffers in the study of proteases. I. Comparative study of methods of measuring p_H when determining pepsin by the Gross method. I. A. SMORODINTZEV AND A. N. ADOVA. *Bull. soc. chim. biol.* 7, 1060-7(1925).—Colorimetric detns. of p_H with methyl violet agree satisfactorily with electrometric measurements, with Gross' method. Methyl violet is unsatisfactory in the presence of glycerol. Casein solns. prepd. by the procedure of Gross possess a p_H almost permanent, and unaffected by boiling. Diln. of natural and artificial gastric juices with H_2O increases the p_H , as does preservation. Boiling does not influence it. A mixt. of casein and pepsin following the procedure of Gross has a p_H 1.04, which is scarcely altered during digestion. A soln. of casein in HCl possesses feeble buffer properties. **II.** Influence of buffers on the digestion of casein by pepsin. *Ibid* 1068-70; cf. *C. A.* 20, 211, 214.—The buffers HCl/glycine (p_H 1.14), HCl/HCl (1.2) and HCl/citrate (1.14 and 1.274) neither retard nor accelerate the digestion of casein by pepsin in the procedure of Gross. A. T. CAMERON

The sugars furnished by gein (geoside); preparation of vicianose by enzymic hydrolysis of this glucoside. H. HÉRISSEY AND J. CHEYMOL. *Bull. soc. chim. biol.* 8, 50-5(1926).—See *C. A.* 20, 435. A. T. CAMERON

The presence, in emulsin of almonds, of two new enzymes, primeverosidase and primeverase. M. BRIDEL. *Bull. soc. chim. biol.* 8, 67-70(1926).—See *C. A.* 19, 2514, 20, 435. A. T. CAMERON

The oxygen content of methemoglobin. M. NICLOUX AND J. ROCHE. *Bull. soc. chim. biol.* 8, 71-97(1926).—See *C. A.* 19, 3302, 3530. A. T. CAMERON

Methemoglobinization: action of hydroxylamine on hemoglobin. J. ROCHE. *Bull. soc. chim. biol.* 8, 98-112(1926).—A quant. study of the action suggests that it is most correctly represented by the equation. $11NH_2OH + 6HbO_2 \rightarrow 11b + 5HbO + 2N_2 + 3NH_4NO_3 + 9H_2O + NH_3$. A. T. CAMERON

New experiments simulating living objects. HERRERA. *Compt. rend.* 182, 462 (1926).—Two solns. are required: (1) gasoline 100 cc., olive oil 50 cc. and (2) NaOH 14 g., rhodamine 1 g., H_2O 100 cc. A few drops of soln. (2) are poured on soln. (1). The drops subdivide, move about slowly, elongate, form vacuoles and constantly change shape, in general closely simulating amebic forms. The smallest droplets resemble infusorial forms, ascending and descending. The phenomena last for some time, even for 1 hr. if the oil is only 5%. The movements probably originate from diffusion currents, changes in the osmotic pressure, and surface tension and other phys. chem. influences. C. C. DAVIS

Maltase. VIII. Direct fermentation of maltose by yeast rich in maltase. RICHARD WILLSTÄTTER AND EUGEN BAMANN. *Z. physiol. Chem.* 152, 202-14(1926); cf. *C. A.* 20, 1244.—With yeasts rich in maltase the optimum p_H for fermentation of maltose is 4.5 and at this acidity the activity of maltase is completely suppressed. Hence when maltose is fermented in acid medium the fermentation is a direct one and not preceded by hydrolysis. In the fermenting medium the enzyme would meet more favorable conditions than those under which the enzyme detn. is performed, since fermentation continually removes inhibitory products. This fact does not, however, invalidate the conclusion stated above, since the amt. of inhibitory cleavage products is very small in the 1st part of the expt. and yet even here hydrolysis is much less than the fermentation in the parallel expt. Maltose fermentation occurs over a wide p_H range, e. g., 3.0-6.5, without much influence on the rate. The induction period is very small, especially with p_H optimum. Distillery yeasts poor in maltase also ferment maltose, but the optimum here is p_H 3.5 and the induction period is much greater. A. W. DOX

Cytochrome, the porphyratin formed by its cleavage, and the related porphyrin

O. SCHUMM. *Z. physiol. Chem.* **152**, 147-59(1926) —Cytochrome, the respiratory pigment recently described by Keilin (*C. A.* **20**, 58), is probably closely related to, if not identical with myohematin. The presence therein of an Fe-pyrrole complex is now established by the prepn. of a porphyratin which may be obtained from plant sources, e. g., sugar beet, in a yield corresponding to the intensity of the cytochrome spectrum. Treatment of the porphyratin with $(\text{NH}_4)_2\text{H}_2\text{O} + \text{AcOH}$ splits off a porphyrin-like pigment which spectroscopically resembles α -porphyrin. Introduction of Fe then gives a porphyratin apparently identical with α -hematoporphyrin. Fischer's conclusion that porphyrin synthesis by yeast does not progress beyond the coproporphyrin stage is contradicted by a study of numerous yeast samples from various distilleries. The spectra of the pyridine exts. revealed without exception a predominance of porphyratin, and the presence of porphyrin could be demonstrated only by recourse to AcOH and Et_2O extns.

A. W. DOX

Plant proteases. IV. The ereptic components of some plant proteases. RICHARD WILLSTÄTTER, WOLFGANG GRASSMANN and OTTO AMBROS. *Z. physiol. Chem.* **152**, 160-3(1926); cf. *C. A.* **20**, 1245 —The instability of erepsin must be taken into account when examg. plants and fruits for their protease components. The dry enzyme prepn. from pineapple is without action on dipeptides, while the freshly pressed juice is active. A difference in activity was noted between the juice of fresh and that of wilted fruit. Pumpkin protease was active toward leucylglycine, although this action was feeble compared to that of its other protease components. Erepsin could not be demonstrated in commercial dry prepn. of papain, but the possibility remains that it may be found in the fresh latex of the immature fruit. The ereptic component of yeast protease is characterized by instability. **V. The individuality of some plant proteases.** *Ibid.* 164-82.—In his early work on plant proteases Vines ascribed peptone formation and peptone cleavage to 2 sep. enzymes. These he claimed to have sep'd. by extn with 2% NaCl. Quant. methods for estimating enzyme action were not employed. It is now shown that the tests used by Vines for distinguishing the 2 supposed enzymes, viz., the digestion of fibrin and the color test for tryptophan, were of such unequal delicacy that a negative tryptophan test was not valid. Moreover, in the fibrin test an enormous excess of enzyme was used, so that a considerable loss resulting from the NaCl treatment would not have been apparent here, but would have rendered the tryptophan test subliminal. Far more satisfactory for purposes of comparison is the present method of detg. the loss in wt. of fibrin and the increase of free carboxyls in peptone or gelatin by titration in alc. soln. Dried fibrin, thoroughly ground and passed through a 0.2-mm. sieve, is preferable to fresh fibrin. After the digestion with enzyme prepn. the mixt. is filtered, the residue dried and weighed and the loss calcd. By using these quant. methods for detg. peptone formation and peptone cleavage no evidence could be obtained of any sep'n. of enzyme components by means of NaCl extn. or alumina and kaolin adsorption. Papain digests fibrin at the p_{H} optimum of 7.1 to about 60%, after which further digestion proceeds with extreme slowness. Papain activated by HCN, on the other hand, digests fibrin completely and at a uniform rate. The fibrin residue is attacked only with difficulty by further treatment with fresh papain, but readily by papain-HCN. The duration of the HCN activation has no distinct influence on the hydrolysis. Pumpkin protease, the optimum of which is also at p_{H} 7.2, attacks fibrin more readily than other substrates. The action of papain on peptone, even after the HCN activation, is relatively slight, and the negative tryptophan reaction of Vines is not conclusive. The p_{H} optimum here lies between 5.0 and 5.2. By using Vines's method of fractionation of enzyme prepn. by means of NaCl extn. the relative activity toward fibrin and peptone remained the same in all fractions. Unlike trypsin, the adsorption of papain by $\text{Al}(\text{OH})_3$ occurs most readily from NH_4OH soln. especially in the presence of EtOH . Elution by 0.02 N AcOH then yields a more active prepn. but the relative activity toward fibrin and peptone remains const. Pumpkin protease is more readily adsorbed from acid soln., and here again the residual soln. and the adsorbate show the same relative activity toward fibrin and peptone. With kaolin the reaction of the medium has little influence on the adsorption. Fibrin itself adsorbs papain but does not effect any sep'n. of the supposed components of the enzyme. The digestion products which are formed during the adsorption pass into the residual soln. and appear to inhibit the digestion of fibrin more than that of gelatin. NaF is without influence on peptone digestion by papain with or without HCN, but inhibits somewhat the digestion of fibrin by papain-HCN.

A. W. DOX

Porphyrins from blood pigment. IV. The constitution of the porphyrins. ARNO PAPENDIECK. *Z. physiol. Chem.* **152**, 215-29(1926); cf. *C. A.* **19**, 303, 2674; **20**, 770.—In Willstätter's structural formula for hematoporphyrin the 2 hydroxymethyl side chains

are assumed to originate with hydration of an ethine bridge within each of 2 pyrrole rings in the hemin mol. The presence of unsatd. side chains is now generally accepted, and even an acetylenic linkage in the case of ooporphyrin, but the assumption of an ethine bridge in the Fe complex of a porphyrin or even in the more intricate structures of the blood pigments is no longer justified. Expts. with electrolytic and catalytic hydrogenation of several porphyrins throw some light on certain structural relationships in which the unsatd. side chain is concerned. Hemateric acid yielded meso-porphyrin, Nencki's hematoporphyrin gave a new deriv. for which the name *oxymeso-porphyrin* is proposed, and hemoporphyrin gave mesoporphyrin or a porphyrin indistinguishable from it, when hydrogenated by either method. These transformations confirm the existence of 1 or more unsatns. in the side chains of the porphyrins.

A. W. DOX

Temperature inactivation of sucrase. HANS V. EULER AND KARL JOSEPHSON. *Z. physiol. Chem.* **152**, 254-63(1926); cf. *C. A.* **19**, 2675.—Partial inactivation of sucrase by heating in aq. soln. and at optimum acidity effects no change in the affinities of the enzyme for the different forms of glucose or for fructose. Even in the presence of glucose or fructose as protective substance the heat inactivation causes no appreciable change in the affinity relations. If the inactivation can be traced to an alteration of the "colloidal carrier" of the enzyme complex, this denaturing process should not result in any alteration of the sp. properties of the enzyme portion designated as substrate-binding groups.

A. W. DOX

Fermentation of galactose by yeast after preliminary treatment with this sugar. II. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* **152**, 249-53(1926); cf. *C. A.* **19**, 2834; **20**, 929.—In addn. to the numerous differences previously observed between top yeasts and bottom yeasts it is now shown that the capacity to ferment galactose is acquired much more slowly by the former than by the latter. The varieties tested were distillery top yeast R and brewery bottom yeast II, which are believed to be representative of the 2 types employed industrially throughout Germany and Sweden. English top yeast differs in many respects from German top yeast, and possibly might show a difference also in its response toward the galactose treatment.

A. W. DOX

Protein chemistry. III. The constitution of the proteins. PERCY BRIGLE AND ROBERT HELD. *Z. physiol. Chem.* **152**, 230-48(1926).—Various conceptions of protein structure have been advanced from time to time. These include polypeptide chain, pyrrole rings, oxazoline rings and diketopiperazine rings. No direct evidence of the presence of pyrrole or oxazole nuclei has yet been presented, and the evidence in favor of the diketopiperazine structure is not considered altogether conclusive. A serious objection to all of these modes of linkage of the component amino acids is the O:N ratio, which in proteins varies from 1.28:1 in lactalbumin to 1.12:1 in elastin. In regard to the extra O in the terminal COOH, which in a large complex would be negligible, the O:N ratio for the acid-amide or diketopiperazine structure should be 1. Hydroxyamino acids are not known to be present in sufficient amt. in proteins to account for the higher O:N ratio. In lactalbumin, for example, the known cleavage products account for 84.2% of the protein, and here the extra O of hydroxyglutamic acid is offset by the additional N of the diamino acids. As a working hypothesis the possibility is suggested that shorter polypeptide groupings may occur in parallel chains connected by a CO bridge. Two possibilities then arise, (1) the linkage of terminal NH₂ groups through CO to form urea complexes and (2) ester-like complexes between the terminal carboxyls and polyatomic alcohols. Such a structure would be in harmony with the occurrence of polypeptides among the cleavage products of proteins and with the susceptibility of proteins to hydrolysis by enzymes. The expts. described deal with the behavior of simpler complexes of this type, viz., carbonyl-bis(dipeptide) toward C₆H₅(CO)₂O fusion, NaOBr and pepsin. These reagents were selected because they act upon proteins without attacking the polypeptide linkage. Fusion of the ester of carbonyl-bis(glycylglycine) (I) with C₆H₅(CO)₂O breaks down the urea linkage with formation of phthalylglycylglycine ester. The failure of NaOBr to act on I is due to the insol. of the latter, since it readily decomps. the free acid liberating CO₂ and N, then splitting the peptide if an excess of the reagent is employed. Neither I nor its free acid is, however, attacked by pepsin. No significance should be attached to this negative result until other carbonylbispeptides have been tested, since glycolic derivs. might be expected to exhibit anomalous behavior.

A. W. DOX

The enzymes contained in taka-diastase preparation. TOKUTSCHI SANO. *J. J. Shp. Tokyo* **42**, 730-4(1922); *Japn. J. Med. Sci.* **2**, 25-6.—S. detected catalase

lactase and emulsin, besides maltase, invertase, trypsin, lab, erepsin, lipase, hemolysin, adrenalase, glucoisomaltase etc., which had been found before.

Chemical constitution of spermine. II. The methylation of spermine. H. W. DUDLEY AND OTTO ROSENHEIM. *Biochem. J.* **19**, 1032-3 (1925); *C. A.* **19**, 1117. By methylating spermine, $C_{30}H_{52}N_4$, ten methyl groups are taken up, giving a quaternary ammonium base, $C_{20}H_{60}N_4(OH)_4$ and indicating that two of its N atoms are primary while the other two are secondary.

Notes on spermine. H. W. DUDLEY AND OTTO ROSENHEIM. *Biochem. J.* **19**, 1034-6 (1925).—Spermine is identical with musculamine, neuridine and gerontine, bases which have been obtained from calf muscle, human brain and dog liver, resp., by earlier investigators. Spermine is absent from bull semen, ox blood, cow milk and hen egg (cf. preceding abstr.).

Tyrosinase, its action on phenols and on tyrosine and other amino acids. R. A. MCCANCE. *Biochem. J.* **19**, 1022-31 (1925), cf. *C. A.* **19**, 2060. All the aerobic expts. were done in Barcroft differential micro respirometers and the anaerobic expts. in Thunberg vacuum tubes. Tyrosinase catalyzes the reduction of methylene blue by a soln. at pH 8 to p -cresol + glycine. When tyrosinase acts on tyrosine the action depends upon the fact that the latter is both an amino acid and a phenol, the amino acid acts as a coenzyme for the oxidation of the phenol. The spontaneous oxidation of the phenols exand. is independent of KCN.

A further note on the kinetics of enzyme action. G. E. BRIDGES. *Biochem. J.* **19**, 1037-8 (1925); cf. *C. A.* **19**, 2060.—A further modification of the equation of Michaelis and Menten (*C. A.* **7**, 2232).

Interaction of free amino nitrogen and glucose. HENRY BORSOOK AND HAROLD P. WASTENEYS. *Biochem. J.* **19**, 1128-37 (1925).—In alk. soln. in the presence of glucose, the free amino N of glycine and of complex derivs. of protein (peptic digest of albumin, Witte peptone and Parke-Davis peptone) was found to decrease, and the mixts. acquired the property of reducing methylene blue, which, in some cases, is accelerated by phosphate.

Oxidation of acetoacetic acid and ester by hydrogen peroxide and its biochemical significance. P. W. CLUTTERBUCK AND H. S. RAPER. *Biochem. J.* **20**, 59-68 (1926). An aq. soln. of the Na compd. of acetoacetic ester, or of the acid, is readily oxidized by H_2O_2 in the cold. On distg. the products of the reaction under reduced pressure, the aq. distillate reduces Fehling soln. in the cold and gives an osazone. From it mono-hydroxyacetone (acetol) was isolated. In addition, by subsidiary reactions, the following substances are produced: diacetylsuccinic acid, acetylacetoacetic acid, acetylacetylacetone, acetic acid, glyoxylic acid and oxalic acid. The authors discuss the mechanism of the reaction in relation to the later stages of β -oxidation, the possible derivation of carbohydrate from acetoacetic acid and a mode of origin of substituted pyrroles in living organisms.

Nature of the action on a photographic plate of sawdust and cholesterol irradiated by a mercury vapor quartz lamp. N. S. LUCAS. *Biochem. J.* **20**, 23-5 (1926). The action on a photographic plate of sawdust after irradiation by ultra-violet rays is not due to any secondary radiations given out by it (Hume and Smith, *C. A.* **19**, 1150), but probably to the production and subsequent gradual emanation of either H_2O_2 or O_3 (see Russell, *Proc. Roy. Soc. London* **74**, 131 (1906)). Similar expts. were carried out on cholesterol. This substance was melted on a roughened glass plate, and after irradiation placed in contact with a photographic plate. The fog produced was intense. When, however, the plate was sep'd. by quartz, no fogging occurred.

Tyrosinase-tyrosine reaction. IV. Note on the identity of tyrosinase from different sources. H. S. RAPER AND H. B. SPEAKMAN. *Biochem. J.* **20**, 69-72 (1926), cf. *C. A.* **18**, 402. —R. and S. prep'd. tyrosinase from the mealworm (*Tenebrio molitor*) and *Agaricus do.ophilus*. In each case the enzyme produced the same red comp'd. with tyrosine. These results contradict Gortner's expts. (*C. A.* **20**, 210).

Production in vitro of black pigments derived from hemoglobin. II. G. VERNONI. *Sperimentale* **70**, 1013-5 (1925), cf. *C. A.* **19**, 1577. —In the presence of serum and $HCHO$ an alc.-HOAc soln. of hematoporphyrin gives black granules much like those previously obtained with hemoglobin. Chlorophyll does not yield granules.

Separation of the lactic-acid-forming enzyme from the muscle; some of its properties. OTTO MEYERHOF. *Naturwissenschaften* **14**, 190-8 (1926). —By careful extn. at -1° or -2° with isotonic KCl soln. of chopped frog muscle and sharp centrifugation, a transparent granula-free ext. can be obtained of strong enzymic activity. It is almost free from cleavable carbohydrate and forms hardly any lactic acid spontaneously. The following results were obtained with it: Lactic acid is formed from glycogen or

starch at a slowly decreasing rate of 0.15 to 0.2% per hour (calcd. on wt. of fresh muscle) at 20° and p_H 7.4, *i. e.*, about $\frac{2}{3}$ of the spontaneous action of the cut muscle. The cleavage velocity of the first ext. is 5 times as high calcd. on dry substance as that of minced muscle, 100 times more than that of intact muscle. The enzyme is sol. in water, precipitable with acetone and can be dried with ether, retaining $\frac{1}{3}$ of its activity. Kept on ice the ext. loses its activity in $\frac{1}{2}$ day, instantaneously at 37°. It is filtratable through a Berkefeld candle and separable by ultrafiltration from the coenzyme (*C. A.* 16, 2545), which is essential to its action. The enzyme attacks hexoses (also glucose) and disaccharides (maltose, amylobiose) (*cf. Laquer, C. A.* 16, 2545) weakly. For moderate concns. (0.2 to 0.5%) the rate of lactic acid formation from glycogen, starch, amylopectin, amylose or trihexosan is about the same (dihexosan acts less vigorously); the last substances react at higher concns. (1 to 2%) more strongly than glycogen. Lactic acid is also formed by it from hexosediphosphoric acid (from yeast) and its products: fructosemonophosphoric acid (Neuberg) and hexosemonophosphoric acid (Robison). The action on starch or glycogen is, however, more vigorous, showing that the phosphoric esters are not intermediates. Addn. of phosphoric acid to the ext. somewhat reduces the initial speed of the action in glycogen, but increases the final yield.

B. J. C. VAN DER HOEVEN

Structural problems of protein chemistry from an enzymic point of view. ERNST WALDSCHMIDT-LEITZ. *Naturwissenschaften* 14, 129-33(1926).—A review (*cf. C. A.* 19, 3496, 2678; 20, 921). The proteolytic enzymes are divided into 4 groups; the sp character of enzyme action is emphasized and from it is concluded that the new conception of proteins as polymerized diketopiperazines cannot in its simple form account for the facts.

B. J. C. VAN DER HOEVEN

Changes in the colloidal condition of serum proteins under physical influences. III. I. PETSCHACHER. *Z. ges. expl. Med.* 47, 348-58(1925).—Detn. of the serum proteins and of the sp. viscosity indicate the changes in the colloidal condition of native serum brought about under the influence of time, heating to 56°, shaking and irradiation with ultra-violet and X-rays. In all cases there was an increase in viscosity and precipitability with $(NH_4)_2SO_4$ without any marked change in total protein. The changes were greatest on heating, less on standing and least by shaking and irradiation. The changes in colloid condition under physical influences seem to be similar in nature but proceeding at different rates. There is a progressive change in the structure of the protein mol., until it is finally denatured. The assumption of a change of albumin into globulin is unnecessary and unsubstantiated.

HARRIET F. HOLMES

Notes on tectin. E. BRESSLAU. *Verh. deut. Zool. Ges.* 29, 91-4(1924); *Ber. ges. Physiol. expl. Pharmakol.* 29, 703(1925).—Pure tectin is prepd. by heating a dense washed culture of colpidium 0.5-1 min. to 36°, then rapidly to 75°, centrifuging the aq. soln. and pptg. the pure tectin with coagulants. Yield: 1 g. from 750 l. culture. The white amorphous powder gives all protein reactions and Molisch's carbohydrate test. It is probably a mucin. Serum in diln. 1:5000 also causes sepn. of tectin from colpidium. Sp. immune serum is pptd., whereby tectin acts as the antigen. The serum obtained by previous treatment with colpidium cultures has also an agglomerating effect. This is probably a common property of all protozoa and was demonstrated particularly for trypanosomata.

MARY JACOBSEN

Metal-albumin compounds. The ultra-violet absorption spectrum as a means of discrimination between adsorption and chemical reaction. A. RONCATO. *Arch. sci. biol.* 6, 263-77(1924); *Ber. ges. Physiol. expl. Pharmakol.* 31, 329(1925).—The compd. formed by shaking egg albumin with Fe powder is an adsorption compd. Its ultra-violet spectrum is the same as that of albumin, while the addn. of a trace of ionized Fe is sufficient to produce an essential change. Oxyhemoglobin shows the same behavior. Starch forms an adsorption compd. with I without any change in the ultra violet spectrum.

MARY JACOBSEN

The occurrence and significance of enzymes in the human skin. ERICH KLOPSTOCK AND A. BUSCHKE. *Dermatol. Wochschr.* 79, 1485-7(1924); *Ber. ges. Physiol. expl. Pharmakol.* 31, 714(1925).—The skin has its own enzymes. The diastase content is the same for the entire skin; lipase, phenolase and tryptase show higher values for the skin of genital organs. The latter and the sole have the highest nuclease content.

MARY JACOBSEN

The liver and spleen pigments of the toad. HIROO OKAMOTO. *Frankf. Z. Pathol.* 31, 16-53(1925); *Ber. ges. Physiol. expl. Pharmakol.* 31, 820(1925).—The 2 pigments, hemosiderin and a decompn. pigment, occur chiefly in the endothelial cells of the liver and in the reticular cells and splenocytes of the spleen, in quantities subject to seasonal variations. The hemosiderin content of spleen and liver is low during the summer.

and remarkably high during the mating period. The decompn. pigment suffers parallel variations in the liver, while its content in the spleen is higher in summer than during hibernation. Spleen atrophy during hibernation is possibly related to these phenomena. The liver may vicariously take care of some functions of the spleen.

The buffering properties of serum proteins. MARY JACOBSEN. *Biochem. Z.* 163, 470-5 (1925).—By a detn. of the buffer value of serum, its ultrafiltrate, and the residue from the ultrafiltration, it is shown that the buffering of the serum is dependent only in small part upon phosphates or other salts of the serum, but in large part upon the protein or non-diffusable fraction.

Oxidation of dihydroxyacetone and glyceraldehyde in phosphate solutions, and the catalysis of the oxidation by heavy metals. F. WIND. *Biochem. Z.* 159, 58-67 (1925). The oxidation of mol. O of dihydroxyacetone and glyceraldehyde in phosphate soln is 20-30 times faster than for fructose. The oxidation is catalyzed by metals, especially Cu, but is slowed up by KCN and $\text{Na}_4\text{P}_2\text{O}_7$.

Enzymes of the skin. III. J. WOHLGEMUTH. The enzyme content of fresh skin of man and animals, and the influence of different kinds of light upon the skin. N. SUGIHARA. *Biochem. Z.* 163, 260-70 (1925); cf. *C. A.* 19, 2368.—The enzymic activity of the skin of the cow, swine, goat, sheep, dog, rabbit, cat, guinea pig, rat, hen, fish and frog are compared with respect to diastase, phenolase, gelatinase, and lipase. The skin of the rat is very rich in diastase and phenolase. There is no parallelism between the activity of the skin and of the blood. Irradiation of the skin with natural and artificial sunlight causes an increase of phenolase but a decrease of diastase and lipase activity, while ultra-violet light causes a decrease of the activity of phenolase, without affecting that of diastase and lipase.

Activity and heat stability of enzymes. Relation between rennet and pepsin. J. WOHLGEMUTH AND N. SUGIHARA. *Biochem. Z.* 163, 253-9 (1925).—Salts which activate diastase render it more stable to heat. The effect of heat upon the protective action of CaCl_2 , $\text{Ca}(\text{NO}_3)_2$, MgCl_2 and $\text{Mg}(\text{NO}_3)_2$ with parachymosin, chymosin, rennet and pepsin indicates that the protective action of CaCl_2 is not due alone to the Ca ion. The difference in behavior of the enzymes shows that pepsin and rennet are not the same, but instead are 2 distinct enzymes.

Enzymes of the human mammary gland. R. TATEYAMA. *Biochem. Z.* 163, 297-307 (1925).—The lactating mammary gland of the human is active with respect to nuclease, phosphatase, diastase, tributyrase and phenolase. It also decomposes a number of sugars into AcH.

Dialyzability and adsorbability of insulin. ELISABETH DINGEMANSE. *Biochem. Z.* 163, 412-21 (1925).—Insulin does not diffuse or electro-dialyze through collodion membranes, and diffuses only to a slight extent through parchment. However, it does flocculate at the cathode with the protein when electro-dialyzed in HCl soln. This pptn cannot be used further to purify the insulin. Insulin solns. with 0.06 to 0.5 mg dry substance per unit are only slightly adsorbed on kaolin in acid or in Na_2CO_3 soln. But upon charcoal, it is adsorbed either from an acid or neutral soln. This adsorbed material cannot be removed by 80% alc. or by solns. buffered at $p_{\text{H}} = 8.0$. Nor does AcOH always remove the adsorbed insulin from charcoal. **Behavior of insulin toward heat and some of its chemical properties.** ELISABETH DINGEMANSE. *Ibid.* 422-7.—Insulin may be heated for $1\frac{1}{4}$ hrs. on a H_2O bath without loss of activity and in N/100 HCl solns. is $\frac{1}{3}$ destroyed by heating for 2 hrs. If insulin is treated with Ac_2O , AcCl or BzCl , its activity is destroyed.

Remark upon the work of M. Dixon and S. Thurlow and that of G. Ahlgren. O. WARBURG. *Biochem. Z.* 163, 252 (1925), cf. *C. A.* 19, 303, 1901.—The system liver mash + hypoxanthine apparently is not part of a respiratory mechanism, since it is not affected by HCN. Methylene blue and oxygen cannot be expected to behave similarly as oxidizing agents in cells, as is implied by Ahlgren.

A tartarylhematin. S. HADIC. *Biochem. Z.* 163, 233 (1925).—Hemin from sheep's blood is treated with 4% tartaric acid in MeOH, and the soln. gently warmed, when micro-crystals of a tartarylhematin sep. from the soln. Analyses indicate that 4 hemin mols. may be present per mol. of the tartarylhematin.

Importance of the study of ions. ALBERT FARINE. *Rech. Ind. Schweiz. Chem.-Ztg.* 1926, 28-31.—Brief explanation of what ions are, with a brief discussion of their importance in physiology, pharmacology, food chemistry and medicine in general.

The effect of exposure period and temperature on the photosensory process in Ciona. S. HEGHT. *J. Gen. Physiol.* 8, 291-301 (1926). The latent period in the photosensory response of the tunicate, *Ciona*, is inversely proportional to the duration of the exposure

period to light. The velocity of the chem. reaction which detcs. the latent period is directly proportional to the concn. of photochem. products formed during the exposure period. Two processes in the form of a coupled photochem. reaction probably govern this response; the secondary reaction proceeds only in the presence of products from the primary reaction. The coupling may be a catalysis or a direct chem. relation. The relation between temp. and the latent period follows the Arrhenius equation in which $\mu = 16,200$. On this basis, the process governing the latent period is tentatively identified as an oxidation reaction catalyzed by Fe. The photocatalytic properties of certain Fe compds. are used as a model for the chem. reactions controlling the photo-sensory mechanism of *Ciona* and *Mya*. CHAS. H. RICHARDSON

Time relations of growth. I. Genetic growth constants of animals. S. BRODY *J. Gen. Physiol.* **8**, 233-51(1926).—Growth is conceived as a complex physiochem. process, the velocity of which is limited or governed, during any given phase, by a single master reaction. The time relations of each phase may be represented by an expression that represents the time relations of a single limiting reaction. The growth curve indicates that there are several consecutive phases of growth each of which has its particular velocity const. Two growth consts. are given for each of several species of mammals including man and methods of computation are discussed. C. H. R.

Studies on the formation and ionization of the compounds of casein and alkali. IV. The transport numbers of the compounds of casein with the alkali earth elements. D. M. GREENBERG AND C. L. A. SCHMIDT. *J. Gen. Physiol.* **8**, 271-8(1926); cf. *C. A.* **14**, 1434.—The values for the transport nos. of casein in solns. contg. alk. earth elements are abnormally high as compared with those obtained for casein in solns. of alkali metals. This is probably due to the fact that part of the base is bound by the casein ion in the form of complex ions. These complex ions probably have a definite chem. compn. CHAS. H. RICHARDSON

Enzyme effect and ionic antagonism. R. HÖBER AND A. SCHÜRMEYER. *J. Gen. Physiol.* **8**, 265-9(1926).—Invertase (from yeast) is sensitive to salts only in the presence of colloids such as gelatin, albumin, globulin and lecithin. Under these conditions its activity is reduced by the salts. The invertase-globulin and invertase-lecithin complexes show an ionic equil. in the form of a physiol. cation antagonism. At certain concns., Na and K on the one hand, and Mg, Ca, Sr, Ba, Al, and La on the other, inhibit one another; by observing these relations the invertase reaches its optimum activity. The salt inhibition and the cation antagonism are lacking on the acid side of the isoelec. point of globulin and lecithin. CHAS. H. RICHARDSON

The influence of electrolytes upon the electrophoretic migration of bacteria and of yeast cells. C. E. A. WINSLOW AND E. H. FLELSON. *J. Gen. Physiol.* **8**, 195-214 (1926).—The effect of electrolytes on electrophoretic charge is probably essentially the same for silica dust, bacteria and yeast cells. The normal negative charge is slightly increased by very low concns. of electrolytes, and markedly so in the case of yeast cells. Higher concns. of electrolytes cause a marked decrease in negative charge; this may at times lead to an isopotential condition or reversal of charge. The effect is probably due to the cation and increases with the valency, but the H ion shows exceptional activity. NaOH behaves like an ordinary univalent salt and increased alk. does not further depress the charge already depressed by salts. Because of the activity of the H ion, increased acidity does not further depress the charge even in salt solns. NaCl exerts less influence on the charge either in high or low diln. than the other compds. with the univalent ions studied. KCl is distinctly more effective than NaCl. Moderately high concns. of electrolytes depress the charge on yeast cells more than on *B. coli*. Silica dust is less affected by univalent and bivalent ions than are yeast cells, but is more affected by $AlCl_3$ than yeast cells or *B. coli*. High concns. of $AlCl_3$ decrease the positive charge produced by moderate concns. Org. substances do not affect electrophoretic velocity till they reach a concn. at which viscosity changes are involved. The following results are in accord with the Donnan theory of equil. as worked out by Loeb (*Proteins and the theory of colloidal behavior*, 1922): (1) the increase in charge as the result of small addns. of electrolytes; (2) the marked decrease in charge with further concn. of electrolytes depending on the valency of the cation. Certain difficulties with this theory as applied to colloidal particles are discussed. C. H. R.

Application of the theory of quanta to peripheral vision. P. LAZAREV. *J. Gen. Physiol.* **8**, 189-93(1926).—This is an extension of a theory of vision previously described (Lazarev, *Arch. ges. Physiol.* **154**, 310, 1913; cf. *C. A.* **8**, 1288; *Ionen-theorie der Reizung*, *C. A.* **17**, 2719). If the chem. formula of visual purple is A, that of its photochem. product B, that of the sensitive substance which under the action of B gives stimulating ions C, and D, stimulating products from C, then: $A \rightarrow P$

$C \longrightarrow D$. B acts as a catalytic agent for the reaction in C and $C \longrightarrow D$ is an autocatalytic reaction. "Every quantum of light energy absorbed by the rods produces a mol. of B , and the mol. of B produces in that of C a mol. of stimulating substance D . D produces in the substance C an acceleration of the reaction and the complete destruction of the substance C in an illuminated rod is produced. In the same time the visual purple is also destroyed." The theory is modified to account for dark adaptation.

CLARA H. RICHARDSON

Isolation of an extremely active non-phosphorized anticoagulant, by prolonged autolysis of organs. DOYON AND I. VIAL. *Compt. rend.* 182, 112-114 (1926), cf. C. A. 19, 1296.—Horse intestine was washed, hashed, and mixed with 2 l. of 0.5% NaCl soln. and 150 to 200 cc. of CHCl_3 for each kg. of tissue. The mixt. was placed in large well stoppered bottles and was allowed to autolyze 3 or 4 months (temp. not stated). The mixt. was then filtered and to the filtrate was added an equal vol. of 95% alc. when a ppt. formed which contained 7 to 8% of P. This ppt. was centrifuged and taken up with warm water when the mixt. was heated on the boiling water bath for at least 1 hr. A ppt. of phosphatides and other material was formed which was filtered out and alc. was added to the filtrate. If a ppt. was formed the process was repeated. If no ppt. was formed there was added to the filtrate in addition to the alc. it already contained, 2 vols. of alc. contg. 1 to 2% AcOH or HCl when the active substance was pptd. This was purified by washing with alc. in the centrifuge until neutral to litmus, then washing with Et_2O and drying in a vacuum. One g. of the substance *in vacuo* prevents the coagulation of 3 liters of blood and sensibly retards the coagulation of 10 l. The substance is acid, slightly sol. in water, and sol. in alk. solns. from which it is reprecipitated by acidified alc. It contains N but not P and it does not reduce Fehling's soln.

I. W. RIGGS

Invisibility of certain flocculates. AUGUSTE LUMBERT. *Compt. rend.* 182, 286-7 (1926).—Serums contg. gelose or starch are toxic, but after prolonged centrifugation become non-toxic. If sugar is added to the serum contg. gelose or starch so as to raise the density to 1.050, the toxicity is not removed by centrifuging.

B. METHODS AND APPARATUS

STANLEY R. BENEDICT

Characterization of hematoporphyrin and urobilin in urine by means of Wood's light. A. POLICARD AND A. LEULIER. *Compt. rend. soc. biol.* 91, 1422-31 (1924). Fluorescopy by means of Wood's light (light from the Hg arc filtered through a Ni screen) is more sensitive than ordinary spectroscopy. The hematoporphyrin must be extd. from the urine, since the latter gives a weak blue fluorescence.

B. C. A.

A microchemical method for the determination of calcium in urine. TAKEO INOUE. *Tokyo Ig. Kyo Z.* 36, 161-7 (1922), *Japn. J. Med. Sci.* 2, 18 (1924). Acidify with AcOH 2 cc. of urine in a centrifuge tube, place in a boiling H_2O bath, and add 0.3 cc. satd. $(\text{NH}_4)_2\text{C}_2\text{O}_4$. Heat 10 min., remove and centrifuge. Wash the ppt. twice with 2-cc. portions of H_2O , dissolve in weak acid and titrate with 0.01 N KMnO_4 . The error of this method is 5-6%.

F. A. CAYORI

Remarks on the measurement of p_{H} of whole blood and of plasma with the aid of the quinhydrone electrode. E. VELLINGER AND I. RACH. *Bot. soc. chim. biol.* 7, 1001-8 (1925).—The quinhydrone electrode is unsuitable for the measurement of the p_{H} of the whole blood, but can be utilized for that of plasma or serum, if account be taken of the protein error. A protein error of 1 millivolt corresponds to 0.1% protein (isoelec. gelatin).

A. T. CAMERON

The micromethod of Kjeldahl simplified, procedure without distillation. (MME.) B. PCHORECKA-LELESZ. *Bull. soc. chim. biol.* 7, 1039-43 (1925), cf. C. A. 19, 1287-7 (1925).—The quinhydrone electrode is employed for traces of NH_3 (dil. by the procedure already outlined, the coned. H_2SO_4 is exdmd. for traces of NH_3 , 1 cc. to 50, neutralize with 30% NaOH with methyl red, and est. with NaOH as usual).

and then the $(\text{NH}_4)_2\text{SO}_4$ is detd. directly after combustion by decompn. with alkali hypobromite and iodometry. A. T. CAMERON

The micromasurement of urea in 0.1 cc. of blood. (MME.) B. POHORECKA-LELESZ. *Bull. soc. chim. biol.* 7, 1085-8(1925); cf. preceding abstr.—Decompose 0.1 cc. blood, serum, or similar liquid with urease at p_{H} 9.2, aerate in a special app.; and est. NH_3 by the hypobromite-iodometric method. A. T. CAMERON

Adaptation of the method of isothermic distillation to the determination of the concentration of blood serum. C. HYRNAKOWSKI AND MISS A. RYCHTER. *Bull. soc. chim. biol.* 7, 1131-8(1925); cf. C. A. 19, 1212.—Results are in good agreement with recent cryoscopic detns. A. T. CAMERON

A sphyximeter. J. P. BOUNHIOL. *Bull. soc. chim. biol.* 7, 1139-43(1925).—A simple app. for measurement of respiratory exchange and basal metabolism. The original must be consulted for details. A. T. CAMERON

Comparative value of the principal technics of deproteinization. H. WUNSCHENDORFF. *Bull. soc. chim. biol.* 7, 1158-67(1925).— HPO_3 should be avoided; filtrates constantly give a positive biuret. CCl_3COOH gives too acid filtrates permitting possible mol. alteration. Tungstic acid gives better results, but the slow filtration renders acid hydrolysis possible. Colloidal $\text{Fe}(\text{OH})_3$ is considered the best precipitant. A. T. CAMERON

Some applications of spectrographic analysis in biological chemistry. E. BAYLE, R. FABRE AND H. GEORGE. *Bull. soc. chim. biol.* 7, 1168-77(1925).—Satisfactory results have been obtained in the detection of Mg in Ca oxalate ppts. in blood Ca detns. under incorrect conditions, in a study of Bi elimination in urine, and in the toxicological identification of Hg. The method is of advantage when the amt. of material is minute, and is easy and rapid. A. T. CAMERON

Modified tests for the alkaloids of the tropine group which have been mixed with organic matter and submitted to putrefaction. MADELEINE MAGNETTE. *J. pharm. Belg.* 7, 757-67, 781-3, 797-805, 821-3(1925).—As a result of extensive researches, the following conclusions were reached: (1) The alkaloids, like atropine, hyoscyamine and tropacocaine, direct derivatives of tropine, may be recovered from decomposing organic material. (2) In cadavers atropine and hyoscyamine resist putrefaction for a considerable length of time. (3) The alkaloids which yield ecgonine on hydrolysis, as benzoylecgonine and cocaine, and ecgonine itself cannot be detected in putrefying cadavers. (4) The identification of the products of hydrolysis of cocaine does not serve as conclusive evidence of the presence of the latter; these products either occur occasionally, e. g., MeOH, or else they exist normally in cadavers, e. g., benzoic acid. (5) Certain factors retard the disappearance of atropine and cocaine in the cadaver, viz: low temperatures, dry ground, exposure to air and especially an acid reaction of the medium. A. G. DUMÉZ

A comparison of Bang's method of blood sugar determination with that of L. Benedict. K. GOTO AND N. OSAWA. *Chug. Ij. Shp., Tokyo* 42, 1422-44(1922); *Japn. J. Med. Sci.* 2, 26-7.—On comparing Mayer-Benedict's method with that of Bang in the detn. of blood sugar of rabbits and dogs in hunger the authors proved that Mayer's method is influenced by creatinine and acetone in the blood and that the degree of increase of blood sugar after fructose administration appears to be higher in Mayer's method than in Bang's. The superior points of Mayer's method are the simplicity of treatment and the ever readiness of the expt. whenever picric acid has been added to the blood soon after it is taken. H. G.

The quantitative method for glycogen determination. TOSHIO OHARA. *Tohoku Ig. Z. Sendai* 6, 124-32(1922); *Japn. J. Med. Sci.* 2, 23.—A comparative study of 3 glycogen detn. methods. The results indicate that Pflüger's method gives the lowest, Yamakawa's the highest and Birry-Gurzevska's an intermediate value. H. G.

A method for the determination of pepsin by Congo red. M. KAWAHARA AND O. PRZCZENIK. *Wiener med. Wochschr.* 76, 129-30(1926).—The method of C. A. 19, 838 is modified by substituting casein for egg albumin. ARTHUR GROLLMAN

The micrometer syringe. J. W. TREVAN. *Biochem. J.* 19, 1111-4(1925).—An app. is described for measuring small vols. of fluid (0.01 cc., with an accuracy of less than $\pm 1\%$). The article does not lend itself to abstracting. BENJAMIN HARROW

A new type of micro-respiration apparatus. WM. K. SLATER. *J. Sci. Instruments* 3, 177-81(1926).—Measurements of CO_2 evolved and O_2 absorbed by living tissue may be made with accuracy to 1 cu. mm. E. H.

Denigé's method applied to Labat's reaction. PEREIRA A. FORJAZ. *Arch. Med. Legal* 1, 53-4(1922).—For the detn. of Br in biol. material (war gas poisoning) the Br is set free by $\text{K}_2\text{Cr}_2\text{O}_7\text{-H}_2\text{SO}_4$ and carried by an air current into a fluorescein soln. The

eosin formed is compared colorimetrically with soln prepd in the same way with a known and approx. equal quantity of Br.

Condensation of ninhydrin with indoxyl. (A new test for indican.) M. TOMITA *J. Oriental Med.* **2**, 189-90(1924); *Ber. ges. Physiol. exptl. Pharmacol.* **29**, 623(1925). Ten cc. of clear urine filtrate treated with Pb acetate and contg 1 cc HCl is heated with a few drops of 5% ninhydrin. A deep red color is formed. The very sensitive reaction is suitable for a detn.

A new reaction of cerebrospinal fluid. G. TACONE *Pediatrics* (Riv.) **34**, 131 (1926).—The reagent consisting of a 5% $K_2Cr_2O_7$ soln. contg 1 drop CCl_3CO_2H to each cc. produces a white turbid ring at the zone of contact with spinal fluid, which in positive cases (meningitis, encephalitis, postencephalitic lesions) is more intense than in normal sera and permanent. Differences in intensity and structure of the turbidity permit differential diagnosis.

Determination of carbon in urine and in dilute water solutions. O. KAUFFMANN AND J. LIEBOWITZ. *Biochem. Z.* **163**, 230-2(1925).—The C content of a soln such as urine or of glucose may be accurately detd. on samples of 0.3-0.4 cc., the Liebn method of combustion being used.

A new method for the estimation of pepsin in stomach contents. I. BOAS *Dent. med. Wochschr.* **51**, 511-2(1925).—The principle of this clinical method is the exposure of a carbohydrate-protein mixt., macromol. of const. compn., to the action of the gastric fluid and the estn., volumetrically, of the starch set free by the digestion of the protein.

Results of gastric juice analysis by the new pepsin method of Boas. P. HIRSCH, MAMROTH AND H. RINDELEISCH *Deut. med. Wochschr.* **51**, 512-3(1925), cf. preceding abstr.—The results obtained for pepsin parallel fairly closely the degree of acidity of the gastric juice in subjects without org. disease of the stomach.

Methods of separation by specific adsorption. A. PODOR AND A. ROSENBERG *Kolloid-Z.* **37**, 234-6(1925).—Expts. have been made to find a systematic method of sepg. substances usually encountered by the biochemist. The substances sepd from one another were albumin, peptone, carbohydrates, aliphatic acids and oxyacids (oxalic, malonic, succinic, lactic, malic, glyceric, tartaric, citric, pyruvic). The method consisted in removing: (1) the acids by adsorption on talcum powder in a relatively strong acid soln.; (2) the albumin from the filtrate by adsorption on kaolin (cf. C. A. **19**, 2224, 3102); (3) the starch from the kaolin filtrate by moist Fe hydroxide. The carbohydrates and peptone or amino acids remain and can be detd. by the ordinary approved methods. With dicarboxylic acids the decrease of the no. of OH groups in a homologous series favors adsorption with talcum. The introduction of OH groups into the mol. changed the talcum adsorption very little.

A spectrophotometric method for determining ammonia in blood. V. M. ARCHANGELSKII. *Arkiv. Biol. Nauk* **24**, 169-78(1924).— NH_3 can be detd. in solns by means of the spectrophotometer, this is a very delicate and accurate procedure. The examn. is made on Nesslerized material and is applicable to quantities ranging from 0.005 to 0.030 mg.; larger quantities cannot be accurately measured. It is, therefore, possible to det. the NH_3 in blood. The NH_3 content of the blood of dogs suffering from tetany increases on standing. This is not apparent in parathyroidectomized dogs on a Ca diet.

The microchemical determination of sugar according to Hagedorn and Jensen. E. KAUFFMANN. *Biochem. Z.* **166**, 207-9(1925).—Slight improvements are suggested for the microchem. sugar detn. in blood.

New micro-physicochemical methods. R. KELLER *Biochem. Z.* **168**, 88-93 (1926).—The cell is the seat of relatively very high elec. tension.

Cataphoresis of substances under physiological conditions. R. KELLER. *Biochem. Z.* **168**, 94-7(1926).—All colored and uncolored compds. show unmistakably and very quickly their behavior in cataphoresis provided their migration is studied under conditions similar to those in living cells, viz., comparatively high elec. tension and with a min. current. The results thus obtained agree very well with the behavior of these substances in plant or animal cells.

Clarification of urine containing sugar with charcoal. I. M. KOLTHOFF. *Biochem. Z.* **168**, 122-7(1926).—Charcoal adsorbs various sugars. Nevertheless a soln. can be freed from coloring matter and be cleared without any appreciable loss of the sugars. In clarifying urines, if the charcoal is used cautiously in just sufficient amt. to decolorize, the glucose is retained quantitatively.

The Hagedorn blood sugar determination. E. MERICH V. FAZEKAS *Biochem. Z.* **168**, 175-7(1926).—The original Hagedorn method is modified to obviate the errors

resulting from spontaneous reduction and oxidation of $K_3Fe(CN)_6$ and $K_4Fe(CN)_6$. The blood is deproteinized according to Bang's U acetate method. To the blood are added 2 cc. of the $K_3Fe(CN)_6$ soln. (3.3 g. $K_3Fe(CN)_6$ + 100 g. Na_2CO_3) and 5 cc. 0.5% $ZnSO_4$, and the whole is boiled 5 min. on the water bath. This is then acidified with 5% $AcOH$ and after cooling 1 cc. 5% KI is added and the material is titrated with 0.005 N $Na_2S_2O_3$. S. MORGULIS

Electrotitration in physiological fluids. II. Determination of iron. ERNST MISLOWITZER AND WERNER SCHAEFER. *Biochem. Z.* **168**, 203-16(1926); cf. *C. A.* **20**, 773.—The e. m. f. of a Pt electrode placed in a soln. contg. Fe^{+++} and Fe^{++} ions is given by the formula $E = A + 0.058 \log (C_{Fe^{+++}}/C_{Fe^{++}})$ volts (20°), where A is a const. (normal potential). So long as both Fe^{+++} and Fe^{++} ions are present E varies little, but changes strikingly as soon as one or the other ion is used up. This sudden and abrupt alteration in the value of E is used as the end point in the titration, which in practice consists of 3 steps. First all Fe^{+++} ions are reduced to Fe^{++} with $TiCl_3$, [(I) $Ti^{+++} + Fe^{+++} = Ti^{++4} + Fe^{++}$]. Next all the $TiCl_3$ and Fe^{++} are oxidized with bromate [(II) $BrO_3^- + 6H^+ + 6Ti^{++4} = Br^- + 3H_2O + 6Ti^{+++}$; (III) $BrO_3^- + 6H^+ + 6Fe^{++} = Br^- + 3H_2O + 6Fe^{+++}$]. The amt. of bromate used up between the end of II and of III, indicated by the sudden changes in E , corresponds to the quantity of Fe . For detg. the Fe in biol. fluids various procedures for ashing are discussed. III. A new method for determining sugar. *Ibid* 217-26.—The detn is carried out in 3 stages: (1) oxidation of glucose in a soln. of $CuSO_4$, $NaOH$ and Na citrate; (2) oxidation of the formed Cu_2O with a Fe^{+++} salt in HCl ; (3) titration of the resulting Fe^{++} ions with BrO_3^- with the sudden change in potential as the indicator. Solns. required are: (1) 75 g. Na citrate dissolved in about 140 cc. boiling water and filtered. Add to this 5.4 g. $NaOH$ in 25 cc. H_2O , and 1.68 g. $CuSO_4$ also in 25 cc., and dil. to 200 cc. (2) Fifty g. $Fe_2(SO_4)_3$ and 200 cc. H_2SO_4 (d. 1.81) are made up to 1 l. with H_2O . Twenty-five cc. of this soln. is mixed with 225 cc. concd. HCl , which gives the oxidizing reagent. (3) A 0.02 N or 0.01 N $KBrO_3$ is made from a 0.1 N soln. (0.783 $KBrO_3$ in 1 l.) which has been standardized with I^- and $Na_2S_2O_3$. Amts. of glucose range from 0.39 to 2.97 mg. with an av. error of ± 0.0016 mg., the probable error of the av. value being ± 0.001 mg. The glucose in blood is detd. as follows: 1.6 cc. blood and 7.5 cc. H_2O are boiled quickly in a small beaker, then acidified with 3 drops acetic acid. With const. stirring 9 cc. of a 1:9 dild. 5% colloidal soln. are added now, drop for drop, then 5 drops N $NaOH$ and 3 drops satd. Na_2SO_4 soln. The contents are transferred to a 20-cc. cylinder, and washed several times with small amts. of H_2O . This is filtered through a dry paper, and 5 cc. used for a blank titration and 2-5 cc. samples are used for the preliminary reduction, etc. S. MORGULIS

Determination of uric acid in blood. AL. IONESCU, I. BIBESCU AND D. POPESCU. *Bul. soc. chim. România* **7**, 65-72(1925).—A volumo-colorimetric method is recommended, based on decolorizing with $K_3Fe(CN)_6$ the blue compd. obtained with uric acid and Folin and Denis' phosphotungstic reagent. Prep. standard uric acid as follows: dissolve 0.10 g. of pure dried acid in 100 cc. of hot distd. H_2O contg. 0.20 g. NaH_2PO_4 and 0.40 g. Na_2HPO_4 , let cool, dil. to exactly 200 cc., and add 1 cc. $CHCl_3$ or 0.1% salicylic acid to prevent development of bacteria. For use, dil. 1 cc. to 10 cc. The soln. should not be more than 2 weeks old. Prep. a soln. contg. 2 g. $K_3Fe(CN)_6$ and 2 g. KOH per 100 cc., and dil. 1 cc. to 100 cc. before use. To standardize the $K_3Fe(CN)_6$, to 2.5 cc. of standard uric acid add 2.5 cc. of 20% CCl_3CO_2H , 2 cc. of phosphotungstic reagent and 20 cc. satd. Na_2CO_3 , shake, and titrate with $K_3Fe(CN)_6$ till decolorized. To det. uric acid in the blood, ppt. albumin with an equal vol. of CCl_3CO_2H , filter, and proceed as above. The reaction is $2K_3Fe(CN)_6 + 2KOH + C_4H_3N_3O_6 \rightarrow 2K_4Fe(CN)_6 + C_4H_3N_3O_6$ (allantoin) + CO_2 . The end point is sharp, and the results are not affected by variations in shade produced by a given amt. of uric acid under varying conditions of concn., time and medium. The reaction is practically not influenced by the other constituents of de-albuminized blood. Under normal conditions the av. uric acid content of the blood is 0.05 g. per l. for serum, 0.15 for whole blood and 0.020% in red corpuscles. Considerable variations are found in pathological conditions. A. PAPINEAU-COUTURE

Histological detection of sugar. J. WOLF. *Centr. allgem. Path.* **36**, 125(1925). The osazone reaction was used. F. B. SEIBERT

The specificity of the microchemical cholesterol reaction with acetic-sulfuric acid. A. SCHULTZ. *Centr. allgem. Path.* **36**, 529-31(1925).—Cholesterol dibromide heated in 90% alc. with $C_2H_5O_2Na$ gives oxysterol, which in turn gives the blue-violet color with the acetic anhydride-sulfuric acid reagent. The oxysterol treated with $FeCl_3$ soln. gives a green color. In the presence of neutral fats the reaction is

negative because oxidation of the cholesterol does not take place. Therefore, the reaction is specific for cholesterol, providing oxysterol can be produced.

F. B. SEIBERT

Detection of albumin in cloudy urines. A. FLORENCE *J. pharm. chim.* [8] **2**, 97–102 (1925).—Ppt. the albumin with $\text{CCl}_3\text{CO}_2\text{H}$ and use Mestrezat's diaphanometric method; or filter the pptd. urine, leaving a dry margin on the paper, wash with a little H_2O , dry at 100° , cut the paper into strips and (a) boil in a test tube with *Millon's reagent* (A), obtain a characteristic red-brown to brick-red color, (b) moisten other strips in a dish with concd. HNO_3 , after 1 min. wash off the HNO_3 with H_2O , then add NH_4OH , obtain a lemon-yellow to orange color if albumin is present. If pptn. of the urine with (10%) $\text{CCl}_3\text{CO}_2\text{H}$ (1:1.5) is slow, add .1 direct, then the paper turns red on drying. If pptn. is abundant, boil with .1 and obtain red brown grains, or heat a trace of the ppt. with a drop of NaOH on porcelain over a strong flame and note the odor of burnt horn.

McCANN, WILLIAM S.: **Calorimetry in Medicine.** *Medicine Monograph. IV.* Baltimore: The Williams & Wilkins Co. 98 pp. \$2.25.

C—BACTERIOLOGY

A. K. BALLS

Production of pyruvic acid by yeasts. E. KAYSER *Ann. Brass. Dist.* **23**, 305 (1925); cf. *C. A.* **18**, 3071.—The pigmented torulae found on grapes and apples give negative results in regard to production of pyruvic acid. With a Sauterine yeast more pyruvic acid was formed in mineral nutrient media contg. Ca lactate or sucrose when 2% of NH_4NO_3 was added than in solns contg. only 0.5%. Solns to which 0.5% of $(\text{NH}_4)_2\text{SO}_4$ had been added gave more pyruvic acid than solns. to which 2.0% had been added. Comparisons were made of the production of pyruvic acid in nutrient media contg. dextrose and levulose by 2 cider yeasts and one wine yeast which fermented dextrose more rapidly than levulose and by Sauterine yeast and pigmented torulae which fermented levulose more rapidly. The first 3 gave more pyruvic acid in dextrose media; the Sauterine gave more pyruvic acid with levulose and the torulae gave no pyruvic acid.

B. C. A.

Formation of gums by bacteria. A. FERNBACH, M. SCHOEN AND S. HAMAWARA *Ann. Brass. Dist.* **23**, 321 (1925).—Fernbach and Schoen (*C. A.* **6**, 3143) showed that a levulosan-producing bacterium was unable to produce the gum except from nascent levulose produced by the bacterium itself in the hydrolysis of sucrose. *Leuconostoc dextranicus*, Beijerinck acts in a manner exactly comparable on the dextrose from sucrose, producing a dextrosan free from reducing power. It produces the dextrosan only from sucrose and no gum is obtained from sucrose previously hydrolyzed by acid or invertase, nor from dextrose or levulose. The max. yield of dextrosan so far obtained is 10% of the sucrose.

Water-soluble vitamin and bacterial growth. S. HOSoya AND M. KUROYA *Tokyo Imp. Univ. Govt. Inst. Infectious Diseases. Sci. Repts.* **2**, 233–85 (1923); *Expt. Sta. Record* **53**, 162–3.—An extensive investigation of the relation of water sol. vitamin to bacterial growth. The vitamin preps. used were an aq. ext. of yeast, 2 oryzanin preps., and the substance isolated by Tsukiye (*C. A.* **17**, 1494) from the phosphotungstic acid ppts. of an alc. ext. of bran by the action of AgNO_3 and baryta. Four media were employed—routine broth autoclaved in neutral reaction at 140° for 2 hours and adjusted to pH 6.8 to 7; routine broth heated to 100° for 1 hr. with the addn. of N NaOH to 0.1 *N* alkyl. and adjusted to pH 6.8 to 7 with N HCl , and 2 protein free synthetic media, Uschinsky's soln. and Fraenkel's soln., both adjusted to pH 6.8 to 7. Care was taken not to carry over traces of autolyzed cells or of the original medium in making the inoculations. The conclusions are based chiefly on the growth of the bacteria tested in 1 of the synthetic media with the Tsukiye vitamin prepn. Some of the bacteria examd. were capable of growing without the vitamin prepn., although growth was in most cases stimulated by its presence, and for others the addn. of the vitamin was absolutely essential for growth. To the first class belong the meningococcus, *B. diphteriae*, *S. aureus* and *citreus*, *B. typhosus*, *B. paratyphosus* A, *B. dysenteriae*, *B. coli communis*, *V. cholerae*, *B. pyocyaneus*, *B. anthracis*, *B. tetani*, *B. oedematis maligni*, and *B. capsulatus welchii*, and to the second *Streptococcus hemolyticus* and pneumococcus. With these organisms the substitution of various amino acids and Na nucleate, indole, creatine, and urea was without effect. The activity of the vitamin as regards growth of hemolytic streptococci was destroyed by autoclaving at 182 – 185° for 2 hrs., but

not at 162° for the same length of time. It proved to be easily adsorbed from neutral aq. solns. by both fuller's earth and animal charcoal. In the presence of 0.025 *N* NaOH it was easily destroyed by heating at 100° for 2 hrs. In similar tests using yeast in place of hemolytic streptococci, it was found that the substance in the vitamin prep. which is essential for yeast growth was not destroyed by treatment with *N* NaOH or *N* HCl even if exposed to a temp. of 140° and pressure of 3.5 atms. for 2 hrs., and in neutral soln. was not destroyed by autoclaving at 160–162° or 182–185° for 2 hrs. It was adsorbed readily by animal charcoal but not to any extent by fuller's earth. The antineuritic factor present in the vitamin prep. was unstable in neutral soln. when autoclaved at a temp. of 140° for 2 hrs. In discussing the difference in properties of the factor required for the growth of hemolytic streptococci, the yeast stimulant and the antineuritic factor, 3 possible explanations are suggested: (1) that the 3 factors may be the same substance, the difference being simply the dose required by each kind of organism; (2) that the vitamin may be a single substance consisting of different parts utilized in different ways by bacteria, yeast and the pigeon; and (3) that the 3 factors may be of entirely different chem. nature. In the opinion of the authors, the third explanation is the most plausible. It is suggested that the yeast is capable of utilizing the simplest and most stable form, the hemolytic streptococcus a less stable, and the pigeon the least stable form. H. G.

The synthesis of the water-soluble vitamin by *B. coli* grown on synthetic medium. M. KUROYA AND S. HOSOYA. *Tokyo Imp. Univ. Govt. Inst. Infectious Diseases Sci. Repts.* 2, 287–304(1923); *Expt. Sta. Record.* 53, 163.—Evidence is presented that *B. coli* is capable of synthesizing the 3 factors present in the Tsukiye vitamin. A pure strain of *B. coli* was grown for 70 generations on one of the synthetic media used in the above study and finally for 3 days on a synthetic agar medium. The culture thus obtained was emulsified in distd. water, allowed to autolyze for 1 week at 37°, and extd with 70% alc. at 85–90° for 4 hrs. in the water bath. The resulting ext. after concn was used as the source of vitamin for the growth of hemolytic streptococci, yeast and rats, and in curative tests for pigeons, with positive results in all cases. As a source of vitamin for the growth of streptococci, the material showed the same properties as the factor contained in the Tsukiye vitamin. Conclusion: *B. coli* is able to synthesize vitamin D or bios, the streptococcus vitamin and vitamin B. H. G.

Studies in bacterial metabolism. LXXIII. Non-glucose-fermenting bacteria and insulin. A. I. KENDALL. *J. Infectious Diseases* 37, 329–32(1925); cf. *C. A.* 18, 3621.—Bacteria that regularly do not ferment glucose could not be made to do so by adding insulin to the media. LXXIV. Effect of insulin on cultures of *B. bulgaricus* and *B. acidophilus*. A. I. KENDALL AND MITZUTERU ISHIKAWA. *Ibid* 333–6.—Insulin had no effect on the amt. of glucose fermented by *B. bulgaricus* and *B. acidophilus*, although the character of the expts. leaves the subject an open question (cf. Noyes and Estill, *C. A.* 19, 1582). LXXV. Effect of insulin on bacterial metabolism. A. I. KENDALL AND MITZUTERU ISHIKAWA. *Ibid* 336–9.—The observations made in the preceding paper were extended to a larger no. of bacteria. Negative results were again obtained inasmuch as the bacteria were not changed in their characteristic action on glucose. JULIAN H. LEWIS

The mechanism of the Russell double sugar tube. M. W. HALL AND G. R. LACY. *J. Infectious Diseases* 38, 14–23(1926).—While the acids produced in the fermentation of dextrose in the Russell double sugar medium are mainly, if not entirely, volatile, their diffusion out of the medium is not the cause of the alk. reaction shown on the slant when typhoid and related organisms are grown. This reaction is due to excess of alk. substances produced from nitrogenous elements in the presence of O. In the absence of O a "mother substance" is formed, which rapidly becomes alk. when exposed to O. The ultimate alk. reversion in the butts of Russell tubes is the result of the diffusion into the butts of O rather than of the alkali formed in the slant portion of the tube. The paratyphoid and colon groups appear capable of producing an alk. reacting substance under anaerobic conditions, thus evidencing a definite difference in metabolism which may prove worthy of further study. No suggestion is made as to the chem. nature of the substance which is so easily oxidized into an alk. substance. JULIAN H. LEWIS

The effect of *Clostridium histolyticum* on the tyrosine in proteins. C. G. KING AND LILLIAN V. HJORT. *J. Infectious Diseases* 38, 42–7(1926).—A quant. study was made of the tyrosine content of edestin, salmon, tuna, cheese, casein, milk, gluten, beef, cottage cheese and peptone before and after growth of *Clostridium histolyticum*. The relation of the digestive action of the organism to the formation of tyrosine crystals in the medium was noted. In 7 of the 10 media, destruction of tyrosine was found. In

the remaining cases there was practically no destruction of tyrosine during approx. 3 months' growth of the organism
JULIAN H. LEWIS

Relations of surface tension to bacterial phenomena. MARTIN FROBISHER, JR. *J. Infectious Diseases* 38, 66-91(1926).—A consideration of the role of surface tension in biology indicates that it is an important factor in bacterial growth, morphology, probably in cell division, and to a less extent in the motility of bacteria, and their ability to retain Gram's stain. Numerous substances are tested as to their ability to lower surface tension and their effect on the growth of bacteria studied. Differences in ability to grow at low surface tensions offer a valuable means of differentiation between species of bacteria. It is possible, by measuring their ability to grow at low surface tensions, to distinguish *B. aerogenes* from *B. typhosus* and *B. morgani*; *B. diphtheriae* from *B. xerosis* and *B. hofmanni*; certain resistant types of streptococci from sensitive types; pneumococci from streptococci. The serologic types of pneumococci do not differ from one another in their sensitiveness to low surface tensions. Low surface tension of the culture medium may be an important factor in defg. the size of individual cells, the rate and extent of cell division, and the cell grouping. The growth producing properties of Hüntoon's "hormone" medium for pneumococci may be improved by raising the surface tension of the medium with charcoal. When prep medium for pneumococci, the surface tension should be raised to some point above 51 dynes. The loss of virulence of pneumococci after treatment with surface tension reducers may be due to the fact that these bacteria disintegrate when they are subjected to low surface tension, and the dissolution of pneumococci by bile may be due to the low surface tension induced by this substance. Na oleate was found to be the most useful reagent for reducing the surface tension of culture media.
JULIAN H. LEWIS

The acidophile bacteria. K. SCHIRK. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 104-18(1926).—Acidophilic bacteria from mouth, caries, intestines, vagina and milk were studied culturally and biochemically. They should be termed acid-tolerant rather than acidophilic.
JOHN T. MYERS

The question of vitamin production by bacteria. W. KOLLATH and B. LICHTEN-TRITT. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 119-25(1926).—*B. coli*, *B. mucosus capsulatus* and intestinal organisms from guinea pigs had no antiscorbutic effect when fed to guinea pigs. Apparently they neither produce nor set free vitamins from food materials. Evidence points toward a difference between the growth-promoting substance for *B. influenzae* and vitamins for animals
JOHN T. MYERS

The biological manifestations of corynebacteria. I. BITTER, M. GUNDEL and T. G. SANCHE. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 132-18(1926).—There are borderline strains of *B. diphtheriae* and *B. pseudodiphtheriae* which cannot be differentiated on cultural or morphological grounds. *B. diphtheriae* produces more acid from glucose than does *B. pseudodiphtheriae*, but some avirulent strains produce more acid than do weak acid-producing virulent strains. *B. diphtheriae* produces more alk than the pseudo types but again there are borderline indistinguishable strains. *B. diphtheriae* reaches an acid max. quicker and the opposite holds for alk. production. By means of animal passage, and variations in content and μ n of media, virulent strains may be changed to avirulent and vice versa
JOHN T. MYERS

Indole production by Bacillus avisepticus. J. CSONTOS. *Centr. Bakt. Parasitenk., I Abt., Orig.* 97, 178-81(1926).—Ten strains of *B. avisepticus* formed no gas from dextrose and did not break up arabinose, xylose or lactose. Indole was produced, but it gave a violet instead of a red color with the Salkowski test.
JOHN T. MYERS

The use of potassium tellurite in differential media. R. GILBERT and E. M. HUMPHREYS. *J. Bact.* 11, 141-51(1926).—A conen of H_2TeO_3 approximating 1/17 000 gave excellent results in isolating diphtheria bacilli from throat cultures and seemed to have no effect on the virulence. Certain Gram positive cocci, some of the higher bacteria, yeasts and molds seem to be inhibited very slightly if at all, while many of the motile bacteria including many anaerobes were markedly inhibited.
J. T. M.

The magnitude of the error due to ammonia and its salts in the Van Slyke amino nitrogen procedure as commonly applied in studies of bacterial metabolism. I. B. PARSONS and W. S. STURGES. *J. Bact.* 11, 165-75(1926).—The Van Slyke method has a high temp. coeff. 18% of the total NH_3 is evolved in 3 min. at 20°, 32% at 25° and 46% at 30°. Increase in diln. of samples markedly hastens the evolution of NH_3 . When NH_3 is removed consistent checks for amino N can be obtained. Without removal of NH_3 results are too high by 18 to 50% of the NH_3 N present depending on the temp. and the size of the sample used. This may cause amino N values to be 50% too high if the NH_3 N is equal to or greater than the amino N.
JOHN T. MYERS

Studies on salt action. X. The influence of electrolytes upon the viability and

electrophoretic migration of *Bacterium coli*. H. J. SHAUGHNESSY and K. I. CRISWELL. *J. Gen. Physiol.* **9**, 123-36(1925).—The electrophoretic charge on *B. coli* is highest in distd. H_2O at p_H 6.0 and 8.0. Under all conditions studied the migration velocity is decreased, but the decrease is not immediate, and is not affected by long exposure. A soln. of p_H 2.0 causes rapid death of the cells and a sharp decrease in electrophoretic charge, whereas a soln. of p_H 11.0, although nearly as toxic as the strongly acid soln., causes only a slight reduction in charge. In distd. H_2O the H -ion concns. near the neutral point are favorable to both viability and electrophoretic charge. In the presence of salts, however, this does not hold true. All concns. of $NaCl$ studied proved somewhat toxic and tended to decrease the charge. $CaCl_2$ was more toxic than $NaCl$ and greatly decreased the charge. Ringer-Locke soln. was markedly stimulating to growth at p_H 6.0, whereas it was somewhat toxic at p_H 8.0. It depressed migration velocity at all p_H values. These expts. show: (1) that a balanced salt soln. may be favorable to viability of bacteria at an optimum p_H , but distinctly unfavorable at more alk. reactions; (2) that the parallelism between viability and electrophoretic charge is not close and the two effects probably follow entirely different laws. C. H. R.

The production of hydrogen by microorganisms. A. C. THAYSEN. *Chemistry & Industry* **45**, 71-2(1926); cf. *C. A.* **20**, 964.—A number of publications seem to confirm Wieland's and Warburg's theories on the chemistry of respiration. Wieland regarded the process of respiration as depending on the faculty of the living cell to activate H atoms present in the respiratory substance. $AcOH$ bacteria convert $EtOH$ to $AcOH$ in the absence of free O provided methylene blue is available as H acceptor. Warburg did not accept this explanation but contended that it was the activation of mol. O by the plasma which was the essential feature of respiration and that this oxidation was due to the presence in the plasma of traces of organically bound Fe which acted as an activating catalyst. Szent-Györgyi and Kluver and Donker believed that both of these theories explain the metabolism of respiration. In earlier papers it is shown that H may be produced by the action of microorganisms on carbohydrates. Biological H production could compete with chemical production only where the H was a by-product. Such a case is found in the butyl alcohol fermentation. It is known that 1 lb. of maize, in addition to other products, yields 5.5 cu. ft. of H . A plant using 20 tons of maize per day would produce one quarter million cu. ft. of H . F. W. TANNER

B. M. DUGGAR

Role of different nitrogenous compounds as sources of nitrogen for higher plants in pure cultures. V. BIALOSUKNIA. *Bull. Inter. Acad. Polonaise*, **B**, 1924, 715-27.—Expts. on the availability of the N of different compds. for the nutrition of mustard and cabbage seedlings in sterile water cultures show that, in addn. to nitrates, the following compds. are also able to serve as sources of N : NH_4 salts, in the presence of $CaCO_3$, nitrites and asparagine. Carbamide, glycine and lecithin serve as sources of N only in the presence of sugars. Peptone, gelatin, egg-yolk and amino acids, except glycine, give no growth. B. C. A.

The presence of β -methylglucoside in the leaves of *Scabiosa succisa* L. (Dipsacaceae). N. WATTIEZ. *Bull. soc. chim. biol.* **7**, 917-24(1925).—See *C. A.* **19**, 3284. A. T. C.

The chemical composition of *Asperula odorata*. Extraction and properties of a new glucoside, asperuloside. H. HÉRISSEY. *Bull. soc. chim. biol.* **7**, 1010-6(1925).—See *C. A.* **19**, 2970. A. T. CAMERON

The glucosides of several species of indigenous orchids. P. DELAUNEY. *Bull. soc. chim. biol.* **7**, 1144-7(1925).—See *C. A.* **19**, 1442. A. T. CAMERON

The presence of loriglossin in *Listera ovata* R. Br. and *Epipactis palustris* Craniz, and some new reactions of this glucoside. C. CHARAUX and P. DELAUNEY. *Bull. soc. chim. biol.* **7**, 1148-50(1925).—See *C. A.* **19**, 2970. A. T. CAMERON

Melilotoside, glucoside liberating coumaric acid, extracted from the flowers of *Melilotus altissima* Thuil. and of *Melilotus arvensis* Wallr. C. CHARAUX. *Bull. soc. chim. biol.* **7**, 1053-9(1925).—These flowers contain a cryst. glucoside, which is hydrolyzed by emulsin or H_2SO_4 to a mol. of glucose and one of coumaric acid. Melilotoside crystallizes from H_2O with 1 mol. H_2O . A. T. CAMERON

The question of a substitute for iron in chlorosis. KARL BORESCH. *Ber. botan. Ges.* **42**, 284-90(1924); *Botan. Abstracts* **14**, 718.—When chromates and manganates are added together to the Fe -chlorotic cultures of *Phomidium Retzii* var. *nigro-violacea*, there results a rebuilding of the chlorophyll and of its water-sol. accompanying pigments in a way similar to that following the addn. of Fe . H. G.

Plant pigmentation and its biological significance. F. R. DA SILVA. *Rev. Tribunaes, Rio de Janeiro* 1923, 109 pp.; *Botan. Abstracts* 14, 723.—Plant pigments and their biological significance are discussed according to their functions, structure and characteristics. A brief summary of conclusions from Bohm to the present day is given and also a bibliography. Life is the function of chloro-assimilation. Pigments, as defined, include not only plastid and crystal pigments but the diffused pigments of the protoplasm, cellular sap, nucleus, of the corky and woody tissues (for which pigments the name of xylochromes is proposed), and of the excretions. Chem. properties of pigments are the basis of the classification. The groups are divided according to functions, chloro-assimilation, protection and nutrition and excretion. Many structural formulas are given. The physiol. classification is rejected. H. G.

Carbon dioxide and p_{H} regulation of the water by some fresh water algae. VI. ADMIR ULEILA. *Ber. botan. Ges.* 41, 20-31 (1923); *Botan. Abstracts* 14, 729.—The algae studied responded quickly to change in H-ion concn. Because of this rapidly to response U. believes that the cell membrane, instead of the whole protoplast, is involved in the reaction. He detd. the p_{H} value for the different green algae and divided them into 3 classes. (The p_{H} boundaries were narrow.) The C and H-S concn. of the water actually detd. the algal associations. The p_{H} value of water and surrounding water were remarkably const., but that of standing water. Extreme fluctuations. Yet such algae as *Cladophora* and *Oedogonium*, with narrow p_{H} limit, actually existed in standing water. They sometimes grew on different rocks, which had a p_{H} regulators. *Oedogonium* with p_{H} 7.5-7.7 grew in a strongly acid water. It was with incrustations called *Psichohormium* which are formed by the bacteria in *Synomonis confervarum* Chol. The latter forms a slimy ring around the algal cell. This bacterium produces the Fe carbonate and CaCO_3 , which form incrustations on the algae. The carbonate dissolves with the increase of CO_2 , freeing OH-ions , thus keeping down the H-ion concn. U. calls this relation "electrical symbiosis." H. G.

Potassium consumption of rye. MAX ESCHENHAGEN. *Botan. Arch.* 7, 418-48 (1924); *Botan. Abstracts* 14, 889.—K consumption is not a function of the K supply but of the concn. of K in soil. H. G.

Starch. H. ZIEGENSPECK. *Botan. Arch.* 7, 251-33 (1924); *Botan. Abstracts* 14, 893.—Differences in the digestibility of starch from different sources may be due to differences in the digestibility of the starch or by the amylase diastase may be due to chem. differences of the starch, which in turn, may be due either to differences in structure of the starch grain or merely to closer packing of individual particles. The permeability for diastase of the plasma layers immediately surrounding the starch grain plays an important role in digestibility. H. G.

Studies in the physiology of the fungi. XVII. The growth of certain wood-destroying fungi in relation to the hydrogen-ion concentration of the media. F. S. WOLPERT. *Ann. Missouri Bot. Gardens* 11, 43-97 (1924); *Botan. Abstracts* 14, 898.—Expts. were conducted with the following fungi: *Pezizomyces arvensis* (Willd.) Fr., *Polystictus versicolor* (L.) Fr., *Pleurotus ostreatus* Jacq., *Sarcophaedum commune* Fr., *Pholiota adiposa* Fr., *Leucites sepiaria* (Wulf.) Fr., *Armillaria mellea* (Ahl.) Quel., and *Daedalea confragosa* (Bolt) Fr. Growth curves for these fungate given to illustrate the relation of growth to active acidity of the culture medium. A greater portion of the growth curves of all of these fungi is on the acid side and in the majority wholly on the acid side. The range of tolerance for acidity is given for each fungus when grown in Richard's and in peptone-nutrient solns., and there is a discussion of the nutritional value of cellulose-nutrient solns. for these fungi when the source of C is the cellulose from filter paper, also white oak, pine, sugar maple and poplar woods. Of all the solns. used, growth of all the fungi is best when peptone is used as the source of both N and C. This is especially true when sugar is used in addition. One N is more available for wood-destroying fungi than are the more forms. Under environmental and physiol. conditions differing from those recorded in this paper the results would vary to some extent. "The p_{H} limits, optimum p_{H} zone, and direction of change in the active acidity of the substratum vary with the environmental conditions." H. G.

The effect of stimulating agents on the growth of roots. WILHELM WOLKENHAUER. *Botan. Arch.* 6, 233-74 (1924); *Botan. Abstracts* 14, 901.—A 0.0005% soln. of CuSO_4 stimulates growth of rye roots. Higher concns. retard growth. Rb nitrate down to 0.0005% retards root growth. A 0.01% soln. of the Rb salt permitted growth equal to the control. Orange G solns. of 0.01, 0.1, 0.3, 0.5 and 1.0% strength stimulate the growth of roots of rye; of these, 0.1% is the optimum. In 0.005, 0.05 and 2.0% solns., growth is just as rapid as in tap water. All higher concns. retard growth. H. G.

Reaction sensitivity of seedlings. CHRISTIAN KRULL. *Botan. Arch.* 6, 331-401

(1924); *Botan. Abstracts* 14, 901.—At a concn. of 0.0019%, H_2SO_4 causes death of oat and rye seedlings. Both withstand concns. of 0.00048% and under. Barley withstands 0.00004% of H_2SO_4 , is badly damaged by 0.00095%, and is killed by 0.00245%. Wheat is like oats and rye. Expts. are listed which deal with H_2SO_4 , HCl, NaOH and NH_4OH . H. G.

Hydrogen-ion concentration in relation to ecological factors. HERMAN KURZ. *Botan. Gaz.* 76, 1-29(1923).—Loams, silts or clays of the upland or slopes, whether of morainic, dolomitic or loess origin, were nearly always found to be more acid than the immediate alluvial flood plain soils. The draining waters were always alk. B. H.

Plum investigations. I. Winter injury to plum during dormancy. M. J. DORSEY AND P. D. STRAUSBAUGH. *Botan. Gaz.* 76, 113-43(1923).—The fruit bud is considered the dormant winter bud formed in late summer or early fall, as distinguished from the flower buds, 1 to 5 in number, inclosed by the scales of the fruit bud. The pith core is a storage region, its cells being packed with materials consisting principally of protein substances, fats and dextrin. Starch was not found. The p_H value of the pith core cells was 4.6. Ca, Mg, K, Fe and P were found. BENJAMIN HARROW

Inherited deficiency in carbohydrate metabolism in maize. W. H. EYSTER. *Botan. Gaz.* 78, 446-52(1924).—The first source of carbohydrates for maize seedlings is the endosperm. When this supply is exhausted, the plant dies, unless it is able to synthesize additional carbohydrates. E. has found a genetic type of maize that digests and absorbs the endosperm, but is unable to utilize the sugars thus obtained. BENJAMIN HARROW

Salt requirements of wheat at different growth phases. W. F. GERICKE. *Botan. Gaz.* 80, 410-25(1925).—The elements required longest in available form in the growth media for normal development of wheat are Ca and Fe. The removal of cultures grown 4, 6, 8 or 10 weeks in complete nutrient solns. to media devoid of N curtailed dry matter production, both of grain and straw, but otherwise the plants appeared normal. The max. development among all cultures was obtained from plants grown 4 weeks in complete nutrient soln. and then transferred into media devoid of P, in which they grew 104 days. BENJAMIN HARROW

Interrelation of relative day length and temperature. B. E. GILBERT. *Botan. Gaz.* 81, 1-24(1926).—Growth expts. and chem. analyses were made with plants of *Xanthium pennsylvanicum*, grown under known conditions of temp. and relative day length. Temp. was found to be a detg. factor in influencing the time of flower primordia formation. This temp. effect, however, was closely associated with a response to relative day length. Chem. analyses of seedlings germinated under high and low temp. conditions showed a marked accumulation of reducing sugars. BENJAMIN HARROW

Changes in nitrogen, potassium and phosphorus content of wheat seedlings during germination and early stages. JEHIEL DAVIDSON. *Botan. Gaz.* 81, 87-94(1926).—Wheat seedlings, within the age limits in which they are used for exptl. purposes, while changing but slightly in P content during germination, vary appreciably in N and P content from the stock seed from which they were obtained, depending upon their age and the conditions under which they were grown. BENJAMIN HARROW

The solutes exuded by root pressure from vines. J. H. PRIESTLEY AND A. WORMALL. *New Phytologist* 24, 24-38(1925).—A chem. examn. was made of a large quantity of exuded sap from the vine. Several dibasic acids occur exclusively. Only traces of org. N are present. A discussion is given of the bearing of the results upon the explanation of the mechanism of exudation pressure and of the substances essential in promoting and maintaining growth in the shoot of the plant. H. R. KRAYBILL

Hydrogen-ion concentration as a determining factor in physiological tissue development in the secondary cortex of the plant. H. PFEIFFER. *New Phytologist* 24, 65-98(1925).—The process of crystn. of Ca oxalate is detd. partly by the p_H of the soln. The monocline form is assumed at low p_H values while the tetragonal and the "gland" forms are found at neutral or basic p_H values. Sclerization of cortical cells occurs at a well defined p_H of the cell wall proteins on the alk. side of their iso-elec. points. H. R. K.

Suggestions concerning the absorption of ions by plants. D. R. HOAGLAND AND A. R. DAVIS. *New Phytologist* 24, 99-111(1925).—Doubt is raised whether the greatest progress will be made by observations upon the effects of many solns. of slightly varying compn. upon the yield of different plants. Many of the most important problems in plant nutrition are concerned with the absorption and utilization of the various ions and the part which they play in plant metabolism. H. R. KRAYBILL

The enzymes of *Stereum purpureum*. J. K. MAYO. *New Phytologist* 24, 162-71(1925).—Of the following enzymes tested for: diastase, inulase, glycogenase, invertase.

raffinase, maltase, emulsin, pectinase, protease, tyrosinase, oxidase and reductase all were found present except maltase, protease and reductase. H. R. KRAYBILL.

The effect of light of different wave lengths on the rate of reproduction of *Volvox aureus* and *Closterium acerosum*. A. BROOKER KLUGH. *New Phytologist* **24**, 186-90 (1925).—If the rate of reproduction is taken as a criterion of photosynthetic activity, photosynthesis is a wave-length phenomenon, red being most efficient, blue much less so and green inefficient. H. R. KRAYBILL.

Light and growth. I. The effect of brief light exposure upon etiolated plants. J. H. PRIESTLEY. *New Phytologist* **24**, 271-83 (1925).—Etiolated plants were found very sensitive to daily exposures of light of only a few min. duration. The results eliminate the explanation that the morphological changes produced upon etiolated plants by light are due to the effect of photosynthetic products. The light action appears to be photocatalytic and is produced upon products of metabolism in the living shoot and not upon the living metabolic machinery itself. H. R. KRAYBILL.

Phytochemical studies. II. AS. ZLATAROFF. *Biochem. Z.* **161**, 379-89 (1925); cf. *C. A.* **17**, 835.—The phosphatides (lecithin) from *Cicer arctium* L. obtained by extn. with Et₂O are sepd. by pptn. with acetone, and fractional pptn. with EtOH. Analysis indicates the presence of a lecithin pentosan, a lecithin glucose and a third lecithin, C₄₅H₈₀NPO₈. Hydrolysis of a fraction similarly obtained liberated betaine. W. D. L.

Absolute and percentage content of the alkaloid of some parts of *Lupinus luteus* L. during vegetation. TH. SABALITSCHKA AND C. JUNGERMANN. *Biochem. Z.* **163**, 415-56 (1925).—Seeds of *Lupinus luteus* L. were assayed for total alkaloid, and similar seeds were then sprouted, and the parts of the developing plants assayed after definite time intervals, so that the rate of change in the total amt. of alkaloid was detd. During germination, there is a decrease, and during growth, an increase in the amt. of alkaloid present. It later decreases markedly, probably due to its transference to new seeds. W. D. L.

Potassium as an antagonist to Röntgen rays and to radium. G. A. NADSON AND A. J. ZOLKEVIC. *Biochem. Z.* **163**, 457-63 (1925).—Seeds of *Sinapis alba* were irradiated with ultra-violet light, or else dipped into solns. of various salts, or exposed to Ra rays for definite time intervals, and the rate of germination and the no. of germinating seeds detd. Those seeds which were treated with solns. of KI and then exposed to Ra grew so much better than those directly exposed to radium, that there must be an antagonism between the K and radium. Na salts showed no such action. W. D. L.

The influence of alcohol upon the growth of seedlings. R. PEARL AND A. ALLEN. *J. Gen. Physiol.* **8**, 215-31 (1926).—When cantaloupe seeds (*Cucumis melo*) are soaked for 3 hrs. in solns. of EtOH (2-16%), and are germinated and grown in the dark in distd. H₂O, the total growth is 9-35% greater than from seeds grown under the same conditions but in distd. H₂O only. This is probably due to a simple selective action of the EtOH whereby the constitutionally weak and defective seeds are eliminated. C. H. R.

Quantitative variations of carbohydrates in the leaves of green plants in the course of one day. P.-P. STANESCU. *Compt. rend.* **182**, 154-6 (1926); cf. *C. A.* **18**, 1005.—Leaves of 6 species of plants were collected hour by hour and were cut up and dried as quickly as possible. The leaf powders thus prepd. were analyzed for mono-, di- and polysaccharides. The results indicate that these plants may be placed in 3 classes. (a) *saccharophiles* (*Polyanthes tuberosa*), characterized by a strong variability of the sol. carbohydrates and a comparatively slight variability of the polysaccharides, (b) *typical amylophiles* (*Medicago sativa*) with characters the opposite to those of class (a), (c) *amylophiles* (*Acer negundo*, *Urtica dioica*, *Carpinus betulus*, and *Rhus typhina*) in which these differences are less pronounced or non-existent. A study of the curves plotted from the results of analysis shows the rhythmic character of photosynthesis which is particularly sharp in daytime and in summer. I. W. RIGGS.

Formation, by heating plant juice, of urea and of a substance giving the same hydrazinic color reaction as formaldehyde. R. FOSSE. *Compt. rend.* **182**, 175-7 (1926); cf. *C. A.* **18**, 1472.—The expressed juice of young leaves of *Acer* and of *Phaseolus* was centrifuged and was treated with a mixt. of phenylhydrazine-ferricyanide-HCl when little or no color was produced. But if the juice is heated for 5 min. on the water bath a

occurs in the heated juice. After heating for 20 min. at 100°, followed by defecation with Pb(AcO)₂ and the removal of the Pb and S, 1 g. of urea per l. is found by the xanthidrol method. The juice without heating contains but a trace of urea. The production of HCHO and urea is attributed to the hydrolysis of a ureide. I. W. R.

Variations of inulin in the grafted Jerusalem artichoke. LUCIEN DANIEL. *Compt. rend.* **182**, 282-4(1926); cf. *C. A.* **18**, 848, 2022, 2360. L. W. RIGGS

Presence of a new oxidase in various fungi. J. WOLFF. *Compt. rend.* **182**, 343-4 (1926).—There exists in certain fungi of the genus *Russula* an oxidase, hitherto unnoticed, which accompanies laccase and tyrosinase, and has the property of oxidizing org. salts of Fe in wine. *Ferrase* is the name proposed for this enzyme. The species *Russula foetens* and *R. emetica* are poor in laccase but rich in ferrase. L. W. RIGGS

Influence of light and temperature on the germination of seeds in the absence of calcium. R. CERIGHELLI. *Compt. rend.* **182**, 483-5(1926); cf. *C. A.* **20**, 435.—In the absence of Ca, roots and stems of pea seedlings grew practically the same in the dark as in the light. In the presence of Ca, the roots and stems in 8 days made about 3 times the growth in the light and 4 times the growth in darkness that was made in the absence of Ca. The temp. exercises a special action upon both roots and stems. In the absence of Ca the root attains the same length at temps. ranging from 11 to 34°. The relation of the temp. to the growth of the stem is somewhat erratic, but the presence of Ca is necessary for the normal growth of either root or stem. L. W. RIGGS

Chemistry of albumin. OSCAR LOEW. *Ber.* **58B**, 2805-7(1925).—The results of the detn. of the constitution of the protein mol. by the usual methods, no matter how definitely they may establish the chem. structure of the mol., by no means permit of drawing conclusions as to how protein is built up in plants. Plants do not first form a series of NH_2 acids and diketopiperazines and then combine them in a definite order and no. into a large mol. but they manuf. the protein mol. with great rapidity from glucose, NH_3 (or asparagine) and sulfates. Except for asparagine, no single NH_2 acid nor diketopiperazine can be brought into relation with the process of protein formation in plants. Hitherto only one investigator (E. Schulze) has thoroughly studied the metabolism of protein in plants and the work of himself and his collaborators (especially Winterstein and Trier) has been entirely ignored by all who have carried out purely chem. investigations on the chem. constitution of protein. After germination of the seeds the reserve protein is peptonized and converted into NH_2 acids which, on the way to the meristems, are oxidized, their N finally appearing as asparagine which, in combination with sugar and sulfates, serves by the formation of new cells to manuf. protein. This new protein, formed in the cells of growing plant organisms, is not indifferent, like the reserve protein in the seeds or the protein of commerce, but is an exceedingly labile substance which as a rule is used up as fast as formed for the organization of the living organoids (cell nuclei, chloroplast, cytoplasm); its rearrangement into the stable, passive protein means the death of the cell. In some plants at a certain definite time more of this labile protein than is necessary for the formation of the living organoids is formed. It then accumulates in the cell juice of the vacuoles in roundish lumps rich in H_2O or in droplets which at 1st sight might be mistaken for fat droplets as they seem to disappear quickly in Et_2O because the resulting coagulum occupies only a very small space; when protein is needed, these formations are coagulated, dissolved and carried away, as can be seen by examg. suitable plants under the microscope at different seasons of the year (e. g., the epidermis of the base of the petiole of *Funkia siboldiana* in May, July and the end of Sept.). In the epidermis of the white base of old leaves of *Iris germanica* or *I. interregna* magnified 500-600 times, each cell, especially in the fall, is seen to contain a large, doubly refractive drop which is easily coagulated by heat, dil. acids, dil. alc., CHCl_3 , water, dil. HCHO , I-KI, quinone, in fact, any poison, considerable H_2O being forced out and a solid hollow sphere or a shrunken, irregularly shaped turbid mass resulting; alkalis, when not too dil., completely dissolve the drop. If a piece of this epidermis is cut through and immediately placed under the microscope, the drops in those cells which have been cut and, as a result, have almost instantly died, will soon be seen to shrink and lose H_2O , in sharp contrast with the large gleaming drops in the uninjured neighboring cells. As the labile protein evidently undergoes a deep-seated chem. change in the rearrangement there is no justification for drawing conclusions as to its mode of formation in plants from the structure of the stable form. C. A. R.

Philippine citrus fruits. A. H. WELLS, F. AGCAOILI, AND MARIA Y. OROSA. *Philippine J. Sci.* **28**, 453-527(1925).—Largely horticultural. Analyses for total solids, sucrose, reducing sugars, citric acid and oil are given for a large number of citrus species grown in the islands. J. J. WILLAMAN

FREY, ALBERT: Calciumoxalat-Monohydrat und -Trihydrat in der Pflanze. Zürich Gebr. Fretz. 65 pp.

E--NUTRITION

PHILIP B. HAWK

The fundamental requirements of a diet. C O SWANSON *Northwestern Miller* 145, 1167(1926).—Tables show the percentage of the different chem. elements found in the human body and the mineral compn. of wheat and mill products. A discussion follows showing the kinds of proteins to use to get the essential amino acids lysine, necessary for growth, and tryptophan, necessary to maintain life. Milk, meat and eggs are excellent supplements to white bread. L H BAILEY

Gas metabolism in the beri-beri of fowls (polyneuritis gallinarum). RYOJIYUN KINOSHITA. *Ni. Byor. Gak. K. Tokyo* 12, 186 7(1922); *Japan J. Med. Sci.* 2, 154 5 (1925).—During exptl beri-beri in fowls the respiratory quotient fell but there was no decrease in the O_2 consumption. These facts are explained on the basis of a defective carbohydrate oxidation in beri-beri. F A CATORI

Ultra-violet light and the antiscorbutic vitamin. P EGGLETON AND I J HARRIS *Brit. Med. J.* 1925, II, 989-91.—Light is unnecessary for the synthesis of vitamin C. Direct exposure of an animal on a scorbutic diet to ultra-violet light did not appreciably retard the onset of scurvy, and the treatment had no curative effect on a scorbutic animal. In cabbage in which the vitamin had been largely destroyed by heat exposure to the Hg vapor lamp gave doubtful regeneration of the vitamin, and infant food rich in C exposed to the rays showed no increase in the vitamin. A T CAMERON

Classification of vitamins. C FUNK. *Bull. soc. chim. biol.* 7, 1017 9(1925). See *C. A.* 20, 62. A. T. CAMERON

Definition of vitamins. MME. L. RANDOIN AND H. SIMONNET *Bull. soc. chim. biol.* 7, 1020-3(1925).—Vitamins are defined as substances still indeterminate chem and phys., which the animal organism cannot synthesize, and which possess properties recognized in certain fractions of the unknown part of the diet which are indispensable for the accomplishment of vital phenomena in the adult, or during the course of development of the animal, and whose absence produces characteristic pathological nutritional changes. It is considered desirable to restrict the term to substances indispensable to the life of the animal (excluding plants). A. T. CAMERON

Avitaminosis B, glucemia, and glycogen reserve. MME L. RANDOIN AND E. LE LESZ. *Bull. soc. chim. biol.* 8, 15-29(1926); cf. *C. A.* 19, 2693.—Further proof is advanced of the specificity of the results of avitaminosis, as contrasted with those of inanition. Deficiency of B results in a definite train of phenomena, which are only complicated by inanition changes. The disequilibrium following B deficiency does not affect the storage of glycogen in liver or muscle, nor its transformation into blood sugar, the increase in blood sugar preceding death being due to deprivation of some substance directly or indirectly indispensable to combustion of glucose. A. T. C

The technic of testing for the presence of vitamin A. J C. DRUMMOND, K. H. COWARD AND JAMES HANDY *Biochem. J.* 19, 1068-74(1925).—To insure the presence of the anti-rachitic factor, irradiated cholesterol is added to the basal diet. The latter consists (in parts by wt.) of purified casein 15, pure rice starch 70, yeast ext 5, salt mixt. 5, lemon juice 5. 10 mg. of irradiated cholesterol is given daily, this being administered to the animals separately in the form of one drop of a soln. in liquid paraffin, or it may be incorporated in the diet to the extent of 20 mg. %, so that each rat obtains 2-3 mg. daily. (The anti-rachitic factor may also be supplied by the addn. to the food of aerated cod-liver oil—that is to say, oil which has been oxidized for 12-28 hrs. by a current of air at 100°, thereby destroying its content of vitamin A, but not affecting the anti-rachitic factor.) BENJAMIN HARROW

Mammary secretion. VI. Vitamin B and the lactating rat's diet. 1. The quantitative relation of vitamin B to protein (continued). 2. Vitamin B requirement of the lactating and non-lactating rat. (Preliminary note.) G. A. HARTWELL *Biochem. J.* 19, 1075-81(1925); cf. *C. A.* 19, 98.—On a synthetic diet contg. 20% casein, 6-8 g. marmitol (the vitamin B prepn.) per 20 g. casein is needed for the mother rat to rear her young. On the same synthetic diet, the lactating rat requires at least 4 times as much vitamin B as does the growing animal. BENJAMIN HARROW

The effect of various carbohydrates on the ketosis of starvation in human subjects. M. W. GOLDBLATT. *Biochem. J.* 19, 948 57(1925).—The plan of the expt. was to undergo a preliminary period of complete starvation and then, having detd. the fasting respiratory quotient, blood sugar and excretion of ketonic substances, to ingest solns. of the various sugars and make similar observations. Glucose, fructose, sucrose and maltose have an antiketogenic action, while galactose, mannose, lactose and glycerol are inert. BENJAMIN HARROW

Studies in nitrogen and sulfur metabolism. H. E. C. WILSON. *Biochem. J.* 20, 76-83 (1926); cf. *C. A.* 19, 2074.—Gelatin ingested during starvation can be retained in part for six days. Meat extractives ingested during N starvation are in part retained. Excess water ingestion increases the output of N in the urine. In the storage of protein, the sulfur is probably retained first.

BENJAMIN HARROW

Studies on the metabolism of arginine and histidine. Part II. Arginine and histidine as precursors of purines. C. P. STEWART. *Biochem. J.* 19, 1101-10 (1925); cf. *C. A.* 19, 2074.—On a diet deficient in histidine and arginine young rats lose wt. and their allantoin excretion is markedly decreased. The addn. of histidine to the deficient diet causes a resumption of growth and an increased allantoin excretion, suggesting, as Ackroyd and Hopkins have pointed out (*C. A.* 11, 1454), that histidine functions as a precursor of purines in the animal body. The addn. of arginine to the deficient diet does not give rise to assumption of growth nor to increased allantoin excretion.

BENJAMIN HARROW

Note on anemia, urobilinuria and intestinal hemorrhage in rabbits in consequence of exclusive nutrition with cow and goat milk. E. BROUWER. *Biochem. J.* 20, 105-7 (1926).—In expts. on rabbits, with either cow or goat milk, in which 5 of the 8 animals developed severe anemia and died after a time, B.'s autopsies lead him to say "not only in human milk-anemia but also in exptl. milk-anemia one should make allowance for decreased building up of hemoglobin; for a symptom (urobilinuria) may be found which indicates an increased loss of red blood corpuscles, and in the deceased exptl. animals an increased loss of red blood by capillary hemorrhage into the intestinal cavity was observed."

B. H.

Use of colloidal ferric hydroxide sol for adsorbing vitamins B and D. ROSA ZAJDEL AND CASIMIR FUNK. *Biochem. J.* 20, 26-30 (1926).—[Z. and F.'s "vitamin D" is the yeast-growth-promoting substance.] The authors have repeated the work of Eddy, Kerr and Williams (*C. A.* 19, 308) in which they used colloidal Fe(OH)₃ gel for the adsorption of vitamin D, and find it unsatisfactory. No better results were obtained when the method was applied for the prepn. of vitamin B.

BENJAMIN HARROW

Vitamin B of lemon rind. S. G. WILLIMOTT. *Biochem. J.* 20, 31-6 (1926); cf. *C. A.* 19, 3295.—0.5 cc. (equiv. to 0.25 g. of rind) of lemon ext. fed per rat per day as the sole source of vitamin B gave nearly normal growth.

BENJAMIN HARROW

Sources of error in the technic employed for the biological assay of fat-soluble vitamins. HARRIETTE CHICK. *Biochem. J.* 20, 119-30 (1926).—C. tends to take Steenbock and Nelson's view (*C. A.* 18, 1320), that vitamins A and D (the antirachitic factor) are to be regarded as 2 members of a whole group of essential factors in diet, any one of which may limit growth; therefore in estg. vitamin A, it is important that a necessary supply of the antirachitic factor be provided. This constitutes a serious criticism of much of the previous work on vitamin A. Variations in the reserves of vitamins A and D which may be present in young rats, and which in turn depend on the diet upon which the young rats are reared, are another source of error.

B. H.

Maintenance of a standardized breed of young rats for work upon fat-soluble vitamins, with particular reference to the endowment of the offspring. H. H. SMITH AND HARRIETTE CHICK. *Biochem. J.* 20, 131-6 (1926).—A description of the lab. methods employed at the Lister Institute, London.

BENJAMIN HARROW

Antirachitic value of fresh spinach. HARRIETTE CHICK AND M. H. ROSCOE. *Biochem. J.* 20, 137-52 (1926).—Spinach grown in the open has little or no antirachitic properties, but when irradiated with ultra-violet rays it becomes powerfully antirachitic, confirming the work of Hess and Weinstock (*C. A.* 19, 845, 2068). "There is no obvious explanation for this discrepancy between the effect of direct sunlight and of artificial ultra-violet radiation." 0.1 g. of fresh leaves of spinach encourages growth and lessens or prevents xerophthalmia in young rats on diets devoid of vitamin A.

B. H.

Antirachitic value of winter spinach. M. A. BOAS. *Biochem. J.* 20, 153-65 (1926).—Winter spinach added to a diet deficient in vitamins A and D caused a marked improvement in the well-being of the rats and in the rate of growth, but the wt. of the skeleton was not, however, proportionally increased; from this it is concluded that winter spinach contains an amt. of vitamin D (antirachitic factor) which is negligible compared with its content of vitamin A.

BENJAMIN HARROW

The variation of the sodium chloride content of the blood and its relation to the food ingested. CHIYOMI FURUKAWA. *Hoku-Etsu Ig. Kw. Z., Niigata* 37, 548 (1922); *Japn. J. Med. Sci.* 2, 15.—The quantity of NaCl in the blood is nearly const. in hungry persons. When 50 g. NaCl was given to a hungry person, the increase of NaCl in the blood occurred 30 m.-1 hr. later. When food poor in NaCl such as bread or meat was given in sufficient amt., the quantity of NaCl in the blood showed a decrease 30 m.

later, which continued for about 2-2½ hr. When, however, 50 g. NaCl was added to the above food there appeared no alteration in the NaCl content of the blood. H. C.

Modern views on vitamins. J. C. DRUMMOND. *J. Roy. Soc. Arts* 74, 369-82 (1926).

The effect of deficiency of vitamin A on the blood platelet count in rats. A. D. STAMMERS. *Brit. J. Exptl. Path.* 6, 312-3 (1925).—No significant changes in the platelet count took place as a result of vitamin A deficiency confirming the view of Bedson and Zilva (*C. A.* 17, 1987; 18, 1321) rather than of Cramer, Drew and Mottram (*C. A.* 17, 2595).

HARRIET F. HOLMES

Flavoring substances in foods. I. The effect of ethyl acetate and a few other substances on the nitrogen excretion in normal dogs and in partly thyroidectomized dogs. II. Effect of ethyl acetate and a few other substances on the rate of growth of rats. III. The thyroid of rats receiving aliphatic esters and essential oils by mouth. U. G. BIJLSMA. *Rep. Dutch Civil Med. Service* 1924, 696-771; *Ber. ges. Physiol. exptl. Pharmakol.* 31, 754-5 (1925).—Dogs can be given 4 cc/kg. AcOEt without injury. Ten cc. are lethal. Salivation, somnolence and deranged coordination are the symptoms. The effect of aliphatic esters is similar to that of the alcs. and perhaps of other narcotics. Female and male dogs with considerably reduced thyroid show an increase of N excretion under AcOEt. Normal male dogs show an increase, female a decrease of N excretion. This is interpreted as an inhibition of thyroid activity in the female with simultaneous increase of N metabolism. AcOAm has the same effect. Cinnamon oil increased the N excretion in male animals. In females no definite conclusion could be reached. No distinct results were obtained with cumarine. II. A growth promoting effect on rats is probable. III. Administration of aliphatic esters or essential oils tends to decrease thyroid activity in rats.

MARY JACOBSEN

The active substances of rice bran against the disease of pigeons fed on polished rice. II. TOKICHIRO IKEDA. *J. Orient. Med.* 2, 90-101 (1924); *Ber. ges. Physiol. exptl. Pharmakol.* 29, 686 (1925).—Extn., purification and sepn. into protein fractions are described. The greatest part of the active substance (detd by the yeast method) was in the choline fraction, but could not be isolated. 25% was in the purine, and a small part in the histidine-arginine fraction.

MARY JACOBSEN

The influence of the thyroid on carbohydrate metabolism. (Thyroid in normal cases and in exophthalmic goiter under Röntgen irradiation.) D. MASELLI. *Problemi di nutrizione* 1, 367-80 (1924); *Ber. ges. Physiol. exptl. Pharmakol.* 31, 69 (1925). Irradiation of normal thyroid in dogs produced hyperglucemia without glucosuria. Irradiation of other parts of the body did not influence carbohydrate metabolism. A similar effect was produced by Röntgen irradiation of the thyroid in a patient with exophthalmic goiter. No histological changes of the thyroid were observed. M. J.

Action of daylight on nitrogen metabolism. GIUSEPPE SUNZERI. *Problemi di nutrizione* 1, 441-9 (1924); *Ber. ges. Physiol. exptl. Pharmakol.* 31, 71 (1925).—N metabolism and N utilization of N compds. in the intestine are lower in the dark than in daylight. Rabbits kept in the dark put on wt. owing to storage of N compds. M. J.

Chemistry of vitamin A. I. Separation of the effective constituent of liver oil and its properties. Preliminary report. KATSUMI TAKAHASHI AND KOZO KAWAKAMI. *J. Chem. Soc. Japan* 44, 590-605 (1923).—One kg. cod-liver oil was sapond. by means of 2 l. of alc. contg. 20% KOH at 80-90° for 30 min. Two l. of 28% alc. soln. of CaCl₂ was gradually added to the soln. with cooling and the mixt. was agitated for 1 hr. The Ca soap and KCl were sepd., the soln. was satd. with CO₂, the solvent distd. off below 60° under reduced pressure and the residue extd. with ether or petr. ether. The ethereal ext. was treated with dil. HCl and the freed fatty acid was sepd. with 50% alc. contg. dil. alkali, the soln. dried with Na₂SO₄ and the solvent was driven off in a current of CO₂. To the residue was added about 50 cc. of 80-90% MeOH; after 2-3 hrs. at 0°. 3-5 g. of cholesterol sepd. Impurities were sepd. by adding digitonin and the soln. was coned. to a reddish viscous sirup, which was once more dissolved in a small quantity of 80-90% MeOH and cooled at -20°; the active constituent then sepd. as a semicryst. substance, in a yield of about 0.1%. By the same method, the active constituents of butter and egg yolk were isolated. A mouse at the point of death because of lack of vitamin A recovered after being given 0.08 mg. of the constituent per day for 10 days. The isolated constituent is an aldehyde, contains no N, is very hygroscopic, is unstable to light and O₂ and is reduced by H₂ in the presence of Pt black, it is stable in Et₂O, alc., and especially in fat. It is insol. in H₂O, sol. in alc., Et₂O, C₆H₆, Me₂CO and other org. solvents. Its CHCl₃ or CCl₄ soln. gives the lipochrome reaction and blue color with Japanese acid clay.

K. K.

Photoactivation of vitamin A, cholesterol, of fats and other substances by ultra-

violet light. S. HAMANO. *Biochem. Z.* **163**, 438-44(1925).—Photographs of compds. and food substances made after irradiation show that cod-liver oil, butter, olive oil, oleic acid and its Ca salt, cinnamic and abietic acids, camphor, borneol, menthol and balsam are photoactive, just as is cholesterol. Other substances, such as glucose, sucrose, starch, satd. fatty acids, succinic, suberic, amino and salicylic acids, anthracene, naphthalene and acetyl alc. are not photoactive. W. D. L.

Antirickettic substances. II. The action of *n*-butyl nitrite on activated cholesterol and the antirickettic vitamin. CHARLES E. BILLS. *J. Biol. Chem.* **66**, 451-7(1925); cf. *C. A.* **19**, 2971.—The antirickettic vitamin in cod-liver oil is destroyed slowly at room temp. and rapidly on heating by *n*-butyl nitrite (used for the production of oxides of N rather than NaNO_2 and AcOH as it is freely miscible with oils and can be accurately measured). Seal oil which resembles cod-liver oil chem. and phys. and is sometimes used to adulterate it has no antirickettic value. Irradiated cholesterol dissolved in seal oil is moderately antirickettic. When irradiated cholesterol is dissolved in cod-liver oil and heated with *n*-butyl nitrite, the antirickettic activity of both are destroyed. The reactions support, but do not prove, the hypothesis that the antirickettic vitamin is identical with the antirickettic deriv. of cholesterol produced by irradiation.

A. P. IOTHROP

Further studies of the metabolism of avitaminosis. A. BICKEL. *Biochem. Z.* **166**, 251-94(1925).—During avitaminosis the body wt. of dogs progressively diminishes (loss up to 48%), the fat depots disappear almost completely, anemia and atrophica changes become prominent although the mixed diet is practically quant. absorbed and is sufficient in calories. The unoxidized urinary C gradually increases, while the N excretion remains unchanged at first but greatly increases in later periods. The quotient of urinary C:N slowly rises. During the middle period of the avitaminosis there is a great increase in the quotient, which B. attributes to an elimination of fat in the urine, but this diminishes again in a later stage. The increased lactic acid excretion during avitaminosis cannot account for the rise in the C:N quotient. The mineral components of the urine likewise increase in avitaminosis; especially is the excretion of P and Ca increased in this condition. Through insulin injections the pathological excretion of unoxidized C through the urine can be reduced in avitaminosis; this regulatory effect of the insulin upon the oxidation of C is only manifested where the C elimination is really pathological. The insulin effect in avitaminosis depends upon simultaneous ionic reaction, and in the absence of certain ions the regulatory influence of insulin upon the excretion of unoxidized C is lost. Of these ions P and Ca are especially indispensable, and these cannot be replaced by one another. Under the influence of insulin the organism retains P, if this is supplied in sufficient quantity, or it mobilizes the P from its tissues if the diet is deficient in P. In general, insulin causes a retention of ions. The increased lactic acid excretion during avitaminosis is likewise reduced to the normal level under the influence of insulin.

S. MORGULIS

Cholesterol content of some organs of the guinea pig fed a scorbutic diet. MOURIQUAND AND LEULIER. *Compt. rend. soc. biol.* **93**, 1314-5(1925).—Lack of vitamin C causes a very marked fall in the cholesterol content of the adrenals without modifying that of other organs or of the blood in any degree.

S. MORGULIS

Casein in the diet of white rats. LIDIA SAVAZZINI. *Compt. rend. soc. biol.* **93**, 972(1925).—Casein causes slight intoxication with loss in wt. and anemia in white rats.

S. MORGULIS

Basal nitrogen excretion. CHARLES RICHTER, JR., AND MINET. *Compt. rend. soc. biol.* **93**, 1270-1(1925).—By basal N excretion is meant the amt. of urea per day and per sq. m. of body surface under good dietary conditions but lacking in N. The av. N excretion of dogs in g. of urea per day and sq. m. was 7.53, but the individual variations are so large (4.1 to 11.3) that the significance of the av. value is not apparent.

S. MORGULIS

Excretion of urea in dogs on a nitrogen-free diet; its relation to the weight and body surface of the dogs, and its individual variations. CH. RICHTER, JR., AND MINET. *Compt. rend. soc. biol.* **93**, 1229-30(1925).—Expts. show that on a N-free diet the N excretion is proportional to the surface, but only for av. values.

S. MORGULIS

Studies of the digestibility of lichenin. ALBERT WALLERSTEIN. *Biochem. Z.* **166**, 157-61(1925).—The expts. were carried out on white mice which were fed on white bread or the same diet in which a part of the bread was replaced by lichenin. During the feeding periods with lichenin the fecal mass is greatly increased. The lichenin is 53-64% utilized.

S. MORGULIS

Metabolism of urinary nitrogen in dogs fed without protein. CH. RICHTER, JR., AND MINET. *Compt. rend. soc. biol.* **93**, 1228-9(1925).—Dogs were fed 3-7 days either

on sugar alone or on a mixt. of sugar and lard in different proportions. The N elimination diminishes during the expt. Thus, if the initial N elimination is 100, it becomes 84, 64 and 41 in the second, third and fourth fasting periods. Sugar causes a diminution in the amt. of N eliminated, and if the N without sugar is taken as 100, it is only 73 on a sugar diet. On a fat diet the N is sometimes diminished and at other times increased, the results being extremely variable. The N elimination is at a min on a diet consisting of fat and sugar.

S. MORGULIS

Phosphorus and calcium metabolism in young rats on a rachitic diet rich in calcium, under the influence of ultra-violet rays, cod-liver oil and phosphates. POUL SCHULTZER. *Compt. rend. soc. biol.* 93, 1005-7(1925).—The Ca and P in both feces and urine have been studied in several groups of rats. The number of mg. retained per g. of body increase is designated as the "retention quotient"; this was as follows under the different exptl. conditions: in the control animals on a rachitic diet and with evident rickets the quotient for Ca was 5.2-4.7 and for P 9.5-8.2 in 2 sep. periods. In the next group the quotient was detd. while the animals were on the rachitic diet and again when ultra-violet treatment was administered, with this result: Ca 4.1 and P 8.1 before, and Ca 10 and P 15.7 after the treatment with cure of the rickets. Similarly in the group given cod-liver oil during a second period the Ca quotient changed from 1.5 to 10.7, and the P from 8.3 to 18.4. Likewise when the rachitic rats were given phosphates the Ca quotient increased from 4.4 to 10.6 and the P quotient from 9.2 to 18.6.

S. MORGULIS

Calcium and inorganic phosphorus in the serum of rachitic rats under the influence of different treatments. POUL SCHULTZER. *Compt. rend. soc. biol.* 93, 1008-9 (1925).—In a number of rachitic rats (condition verified radiographically and also by necropsy) there was on an av. 11.9 mg. Ca and 5.6 mg. P per 100-cc serum. In 4 rats treated with ultra-violet rays the serum Ca rose to 15.2 and P to 8.6 mg. per 100 cc. In rats given cod-liver oil the serum Ca increased to 13.8 mg. and the P to 10.6 mg. per 100 cc. Normal young rats on an ordinary diet fail to show this increase in serum Ca under the influence of cod-liver oil or of ultra violet rays. The healing of rickets resulting from the exptl. adjustment of the Ca and P of the diet (either by increasing P or diminishing Ca) differs from the other 2 forms of treatment, in that the serum Ca and P reach but do not exceed the normal level.

S. MORGULIS

New studies on the relations between age and the appearance of avitaminosis C. C. G. MOURIQUAND AND M. BERNHEIM. *Compt. rend.* 181, 1103-4(1925); cf. *C. A.* 18, 1521.—Tests with guinea pigs, using 10 subjects in each trial, showed that in pigs weighing from 70 to 200 g. sensibility appeared in 11 to 14, av. 13 days, and crepitation in 16 to 23, av. 19 days; with pigs weighing 200 to 400 g. the figures were 6 to 9, av. 7.5 and 13 to 16, av. 14.8 days; with pigs weighing 600 to 800 g. the figures were 13 to 23, av. 16.3, and 23 to 30, av. 25.7 days. The symptoms of avitaminosis C appear sooner in young than in adult guinea pigs but also the symptoms appear sooner in pigs weighing 200 to 400 g. than in younger pigs.

L. W. RIGGS

Experimental production of the pellagra syndrome. GEORGES MOURIQUAND. *Compt. rend.* 182, 347-8(1926).—The pellagra-producing action of maize is exercised only in the presence of a regimen partially disequibrated. Alimentary equil. opposes the pathologic action.

L. W. RIGGS

Reproduction, growth and alimentary equilibrium. (MME.) L. RANDOIN, J. ALQUIER, (MME.) ASSELIN AND (MME.) CHARLES. *Compt. rend.* 182, 91-6(1926), cf. *C. A.* 19, 2365, 3298.—White rats were fed rations contg. 51.5-80% of coarse bran, the remainder of the ration consisting of one or more of casein, butter, sugar and salts. The conditions of alimentary equil. most favorable to growth were not always those most favorable for reproduction. Butter carries the indispensable principles of fertility. Thus in a ration contg. bran 56%, casein 16.8, sugar 25.5 and salts 1.7, sterility was absolute in both sexes. The ration bran and butter sufficed to keep the male fertile but not always the female; the addn. of casein insured the fertility of the female. With butter and casein present it is still necessary to take account of the ratio between the salt and energy constituents of the ration, especially for the female. Of the 8 rations studied, the best, all things considered, contained bran 51.5%, casein 7.8, butter 14, sugar 21.9 and salts (NaCl and CaCl₂) 1.8, in which the ratio of (total mineral matter) to (total digestible carbohydrates) was 1:9.5.

Experimental production of the pellagra syndrome. GEORGES MOURIQUAND. *Compt. rend.* 182, 347-8 (1926).—The pellagra producing action of maize is exercised only in the presence of a regimen partially disequibrated. Alimentary equil. opposes the pathologic action.

L. W. RIGGS

Reproduction, growth and alimentary equilibrium. (MME.) L. RANDOIN, J. ALQUIER, (MME.) ASSELIN AND (MME.) CHARLES. *Compt. rend.* 182, 916 (1926), cf. *C. A.* 19, 2365, 3298.—White rats were fed rations contg. 54.5-80% of coarse bran, the remainder of the ration consisting of one or more of casein, butter, sugar and salts. The conditions of alimentary equil. most favorable to growth were not always those most favorable for reproduction. Butter carries the indispensable principles of fertility. Thus in a ration contg. bran 56%, casein 16.8, sugar 25.5 and salts 1.7, sterility was absolute in both sexes. The ration bran and butter sufficed to keep the male fertile but not always the female; the addn. of casein insured the fertility of the female. With butter and casein present it is still necessary to take account of the ratio between the salt and energy constituents of the ration, especially for the female. Of the 8 rations studied, the best, all things considered, contained bran 54.5%, casein 7.8, butter 14, sugar 21.9 and salts (NaCl and CaCl₂) 1.8, in which the ratio of (total mineral matter) to (total digestible carbohydrates) was 1:9.5.

EDDY, WALTER H.: **Nutritional Factors.** Baltimore: The Williams & Wilkins Co.

F—PHYSIOLOGY

E. K. MARSHALL, JR.

The occurrence of fatty substances in the human ear. KICHIRYO NAKAMICHI. *Ni. Byor. Gak. K. Tokyo* 12, 106-9(1922); *Kyoto Ig. Z.* 19, 1045-70(1922); *Japan. J. Med. Sci.* 2, 141-2(1925).—The fat deposits in the ear are largely glycerol esters. Cholesterol esters are present if the fat deposits are extensive. By means of staining with Sudan III, the distribution of fat in the various tissues of the ear and the variation of fat content at different ages were studied. Usually the fat deposits increase with increasing age and the conclusion is reached that the hard hearing of old age is due in large part to increased fat infiltration.

F. A. CAJORI

Cholesterol metabolism in organisms. I. Cholesterol problem in regard to birds. MASAMICHI YAMAGUCHI. *Ni. Byor. Gak. K. Tokyo* 12, 111-2(1922); *Hokkaido Ig. Kw. Z. Niigata* 37, 1235-78(1922); *Japan. J. Med. Sci.* 2, 143-4(1925).—Cholesterol esters were found more abundantly in the bodies of birds than in human beings. Thirty species of birds were examined and cholesterol esters found in the endothelial cells of all the important organs and tissues. A hypercholesterolemia was produced in fowls and pigeons by the feeding of egg yolks. After such feeding large deposits of cholesterol were found in the liver. Lanolin, when fed, failed to increase the cholesterol of the blood or tissues.

F. A. CAJORI

Presence of an oxytocic substance (posterior hypophysis extract) in cerebrospinal fluid. SHEPARD SHAPIRO. *Arch. Neurol. Psychiatry* 15, 331-40(1926).—Of 28 cerebrospinal fluids from 25 different patients none caused an oxytocic effect on the virgin guinea-pig uterus. No evidence was obtained that intravenous injection of pituitary ext. caused increased secretion of the posterior principle into the fluid within 3 min.

A. T. CAMERON

Variations of phosphatides during liver autolysis. C. ARTOM. *Bull. soc. chim. biol.* 7, 1099-1128(1925).—In the livers of normal dogs the greater part of the fatty acids is combined as phosphatides, presenting very limited individual variations. The total P sol. in CHCl_3 can be fractionated into (a) true phosphatide-P, (b) P of phospho-nitrogenous impurities and (c) P sol. in acetone. The phosphatide index (phosphatide fatty acids/phosphatide P) is close to 18, so that almost all the phosphatides are lecithins or cephalins. During aseptic autolysis of such livers the phosphatides constantly diminish; the degree of diminution is more marked in animals killed during digestion or after administration of HCl than killed when fasting. Presence of excess of triolein or Na oleate slightly slows the phosphatidolysis. The phosphatide index varies very little, indicating that the hydrolysis is essentially a cleavage of the mol. with total liberation of the fatty acids. Sometimes, however, the index is sharply diminished, probably because of formation of marked amts. of intermediate products. Exptl. addn. of fat usually feebly augments the index. P of the (b) fraction diminishes more rapidly than that of (a), while the acetone-sol. P increases, both absolutely and relatively.

A. T. CAMERON

The hypoglucemic action of duodenal secretin. R. NOVOA SANTOS. *Bull. soc. chim. biol.* 7, 1151-3(1925).—Previous positive results (Santos, Barreiro and Criado. *Archiv. Endocrin. Nutricion*, Oct. 1924) are confirmed, both for man, the rabbit and the dog. The depancreatized dog does not respond to the injection of secretin like the normal animal, contrary to the statement of Penau and Simonnet (*C. A.* 19, 1883).

A. T. CAMERON

The corpus luteum as the source of the follicular hormone. C. G. JOHNSTON AND V. L. GOULD. *Surgery Gynecol. Obstetrics* 42, 236-9(1926).—In expts. with rats and rabbits no effect was obtained by injecting the alc.-ether-acetone ext. of carefully collected corpora lutea of pigs. Since the corresponding ext. of liquor folliculi of hog ovaries gave positive results it is concluded that the corpus luteum does not secrete the hormone which produces hyperplasia of the uterus and vagina.

A. T. CAMERON

Studies on the amount of combined carbonic acid in milk. H. TOKURA AND K. OGASAWARA. *Taisho Fujinkwa Gak. Z. Kyoto* 1922, 253-72; *Japan. J. Med. Sci.* 2, 15-6.—It was shown that the amt. of the combined carbonic acid in milk runs parallel to that of the blood.

H. G.

The intermediary metabolism of the kidneys. J. SNAPPER. *Wiener med. Wochschr.* 76, 50-1(1926).—The kidneys can oxidize β -hydroxybutyric acid. The intensity of the ketosis in acidosis depends on the state of this oxidative function of the kidney.

ARTHUR GRÖLLMAN

Distribution of phosphorus and fat in the resting and fatigued muscle of the cat, with a note on the partition of phosphorus in the blood. D. P. CUTHBERTSON. *Biochem*

J. 19, 896-910(1925).—Muscle fatigue causes (a) no change in total P_2O_5 , (b) an increase in the inorg. P_2O_5 of the stimulated muscle, a decrease in the inorganic P_2O_5 of resting muscle, (c) a decrease in the lactacidogen P_2O_5 in fatigued, and an increase in resting muscle, (d) no alteration in the total amt. of inorg. plus lactacidogen P_2O_5 , (e) no effect on the organic acid-soluble P_2O_5 other than lactacidogen, (f) a small increase in the total acid-soluble fraction and (g) no alteration in the phosphatide P_2O_5 . On the P compds. of the blood, the effect of fatigue was an increase in the inorg. P_2O_5 and in the total acid-soluble P_2O_5 , and a decrease in the organic acid-soluble P_2O_5 . The P-contg. skeletal muscles belong to the nucleoprotein group. BENJAMIN HARROW

Fate in the animal body of phenylsuccinic acid and β -phenylhexoic acid. P. W. CLUTTERBUCK AND H. S. RAPER. *Biochem. J.* 19, 911-14(1925); cf. *C. A.* 19, 3097. Phenylsuccinic acid administered to a dog (0.22 g. per kg.) is not easily oxidized, since 61% of the amt. given was recovered from the urine. β -Phenylhexoic acid, administered subcutaneously in the form of its Na salt, was recovered from the urine to the extent of 45%, chiefly as a compd. with glycuronic acid, but no phenylsuccinic acid could be detected. Probably γ -oxidation in this instance does not take place. B. H.

Influence of the administration of certain salts on the yield and composition of milk. A. T. R. MATTICK AND N. C. WRIGHT. *Biochem. J.* 19, 915-20(1925). For raising the plasma Ca content, $CaCl_2$ and NH_4Cl were used, and for lowering it, $NaHCO_3$ and Na_2HPO_4 were used. These were given in large oral doses. Neither the plasma Ca nor the general compn. of the milk was altered by these means. B. H.

Sulphydryl reaction of skin. ERNEST WALKER. *Biochem. J.* 19, 1085-7(1925); cf. *C. A.* 19, 1885. The substance which gives the nitroprusside reaction in skin cannot be extd. with water, despite Kaye's claims to the contrary (*C. A.* 19, 992), and is probably not glutathione but a thermostable sulphydryl constituent of muscle. B. H.

Studies on the physiology of plain muscle. IV. The lactic acid content of plain muscle under various conditions. C. L. EVANS. *Biochem. J.* 19, 1115-27(1925); cf. *C. A.* 18, 854. Lactic acid is present to the extent of 0.03-0.08% in "resting" plain muscle. The amt. is increased when the muscle is made to contract, or by treatment which in skeletal muscle produces *rigor*. The lactic acid production is much greater when the pH of the soln. is 9 than when it is 4.5. The acid rapidly accumulates in plain muscle when kept under anaerobic conditions, but not when kept in O. B. H.

On the presence of cyanate in the blood. ERIK GOTTLIER. *Biochem. J.* 20, 1-5(1926).—Despite Montgomery's assertion (*C. A.* 19, 1874), G. denies that there is any cyanate in blood. BENJAMIN HARROW

Note on the excretion of phosphate during water diuresis. R. E. HAVARD AND G. A. REAY. *Biochem. J.* 20, 99-101(1926).—The rate of phosphate excretion is independent of the water rate even when, owing to copious diuresis, the urinary phosphate is below the level of the plasma phosphate. BENJAMIN HARROW

Determination of bilirubin in meconium and feces of the nursing. VITTORE ZAMORANI. *Clin. pediatr.* 23, 9-19(1925); *Ber. ges. Physiol. exptl. Pharmacol.* 31, 254(1925).—Normal feces of children over 1 year and of adults contain only urobilinogen and urobilin, those of the nursing unaltered bilirubin. Bile secretion begins in the 6th fetal month and biliverdin appears in the meconium. In the first 8 days of life the bilirubin excretion is const., about 0.13% of the feces. It decreases to 0.01% after 6 months. Bilirubin is detd. by the method of Hijmans van den Bergh. M. J.

The significance of the color index of the blood. JAC. J. DE JONG. *Geneeskund. Bladen* 24, 139-69(1925); *Ber. ges. Physiol. exptl. Pharmacol.* 31, 261(1925).—Methods of detn. are discussed and results in health and disease are given. The color index is a measure not of the hemoglobin content but of the size of the cell, since the hemoglobin concn. has always the same value in health and disease. In normal man the vol. of the erythrocyte is $90\mu^3$, its hemoglobin content 26×10^{-12} g., the ratio 1.59-1.512. MARY JACOBSEN

Occurrence and significance of thymus lipoids. ANGELO KYRILOW. *Z. Konstitutionslehre* 10, 460-81(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 31, 276(1925).—Cholesterol esters alone and in mixts. with fatty acids occur in intrathymic tissue in quantities increasing with the age. The Hassall bodies contain phosphatides. The parenchyma shows a varying no. of cells contg. fat. No definite relation between lipid content and certain diseases could be established. Numerous large Hassall bodies with a high fat content were present in 3 cases of uremia. The cells contg. fat were absent during menstruation, in amenorrhoea and during the climacterium. MARY JACOBSEN

The chemical composition of the vitreous body of the eye especially of the extractive matter. TOKICHIRO IKEDA. *J. Orient. Med.* 2, 135-41(1924); *Ber. ges. Physiol. exptl.*

Pharmakol. 31, 925(1925).—The chem. constituents are: proteins, *d*-lactic acid, *l*-leucine (?), *d*-alanine, *l*- and *r*-proline, *l*-phenylalanine (?), *d*-valine (?), *d*-isoleucine (?) and hypoxanthine; 0.15 g. fat and 0.5 g. phosphatides per 29.49 g. fluid. This analysis proves that the vitreous body is chem. different from the retina and the gray matter of the brain.

MARY JACOBSEN

Ammonia content and ammonia formation in blood. III. Source of blood ammonia. J. P. PARNAS AND M. TAUBENHAUS. *Biochem. Z.* 159, 298-310(1925); cf. *C. A.* 19, 3108. —If protein-free blood is allowed to stand, the NH_3 concn. increases, which shows that the NH_3 comes from non-colloidal material. This NH_3 does not come from amino acids, but from some substance not recognized. A comparison of accuracy of colorimetric and volumetric methods for the detn. of small amts. of NH_3 is made, and the former is selected as being the more accurate.

W. D. L.

Activity of sodium in blood serum. L. MICHAELIS AND S. KAWAI. *Bipchem. Z.* 163, 1-7(1925).—In order to det. the active concn. of Na in blood serum, the potential of serum vs. a Na-Hg electrode, and the concn. of Na in a soln. of pure NaCl giving the same potential vs. the same electrode are detd. The difference between the 2 concns is a measure of the Na bound by proteins. The presence of Ca or K ions does not appreciably affect the p. d. The potential of horse serum is the same as that of 0.180 *N* NaCl, whereas analysis of the serum showed a concn. of 0.175 *N*. The agreement is within the limit of error of the method. Therefore, the activity of Na in serum is the same as that in a pure NaCl soln. of the same concn.

W. D. L.

Influence of insulin upon the fat content of rats in avitaminosis and in different conditions of nourishment. K. ONOHARA. *Biochem. Z.* 163, 51-60(1925).—White rats are fed upon diets contg. vitamin A in various amts. and then are treated with insulin and the change in the fat deposits in the body is observed. Insulin (0.8 units per kg. body wt.) shows no fat sparing action in white rats. **Influence of the mineral content of food upon the fat content of the body.** *Ibid* 61-6. —The average fat content of white rats fed upon a diet contg. sufficient amts. of CaCl_2 , MgCl_2 and NaCl is about 1% more than of rats upon a diet poor in salts. **The influence of insulin upon the blood fat content of dogs in avitaminosis.** *Ibid* 67-74. —Dogs are maintained upon a slightly negative N balance, the diet being insufficient in vitamins (not specified). Insulin is then injected into them but no changes in the blood fat or blood sugar are found. W. D. L.

Physiology of glands. L. ASHER. LXXVIII. Influence of the thyroids upon the growth-promoting properties of blood: the occurrence of a growth-promoting substance in blood. S. UCHIDA. *Biochem. Z.* 163, 75-94(1925); cf. *C. A.* 20, 941. —Tissue cultures are grown in the sera of animals from some of which the thyroids and thymus glands have been removed. With the removal of the thyroids, the sera lose some substance which normally promotes growth, so that poor development results. Removal of the thymus has a less well defined effect upon the growth of the cultures, whereas removal of the ovaries seems to have no effect at all. **LXXIX. Dependence of the ovaries upon the excitability of the central nervous system proved by the hyperglucemia after injection of diuretin.** S. UCHIDA. *Ibid* 95-108. —Upon the removal of the ovaries of rabbits, the effect of diuretin is diminished, but there results a hyperglucemia which lasts for several weeks. By removing one suprarenal gland, and sectioning of the splanchnic nerve on the opposite side, the hyperglucemia resulting from injection of diuretin is shown to be of central origin. **LXXX. Nature of the action of specific diuretics; urine secretion.** GEO. M. CURTIS. *Ibid* 109-60. —The diuretic action of *euphyllin* (theophyllin-ethylene diamine) is studied. Injection of glucose simultaneously with the drug repressed the diuresis. Urine chlorides and urea, f. p., elec. cond., org. materials, and osmotic relationships are studied. Neither the secretory nor the mechanical theory of urine excretion explains the action of specific diuretics. **LXXXI. Relation between the thyroids, thymus, spleen, and bone marrow.** H. NAKAO. *Ibid* 161-75. —The function of bone marrow in young rabbits is stimulated by injections of nucleic acid. The effect of the removal of the thyroids, spleen or thymus in various combinations upon this stimulation is observed. **LXXXII. Relation of supra-renals to the development of secondary sex characteristics.** W. KICHNIKAWA. *Ibid* 176-86.

W. D. L.

The thiocyanate content of human blood serum. H. SCHREIBER. *Biochem. Z.* 163, 241-51(1925).—The concn. of the CNS ion in the blood serum of women and non smoking men varies between 0.025 and 0.04 mg. %. With smokers, the value may be 3 times greater. After ingestion of thiocyanates, the concn. in the serum rapidly increases to perhaps 30 times the normal value, and remains above normal for 2 or 3 weeks.

W. D. L.

Decomposition of sugar in human placenta. R. TATEYAMA. *Biochem. Z.* 163,

292-6(1925).—By the detn. of the AcH formed by the action of placenta upon solns. of glucose, sucrose, lactose, sucrose, phosphoric acid, glycogen and starches, it is shown that all are decompd. into AcH. The action, however, is not uniform nor const. Both insulin and *dl*-alanine usually increase slightly the amt of AcH formed W. D. L.

G—PATHOLOGY

II. GIDEON WELLS

The distribution of phosphorus compounds in the blood in tuberculosis. K. LUCILLE McCUSKEY. *J. Lab. Clin. Med.* **10**, 466-74(1925).—A decrease in lecithin content of both the cell and the plasma with a simultaneous increase in acid sol P represents a grave, prognosis while the opposite is favorable. M. believes that the acid-sol P is used in the synthesis of lecithin. The sum of the lecithin and acid sol fractions is equal to the total P, except in the terminal stages of exudative pulmonary tuberculosis, in which the total P is greater than the sum of these two fractions. The additional P fraction is confined to the cell and represents a group not sol in EtO_2Ac or $\text{CCl}_3\text{CO}_2\text{H}$ (cf. *C. A.* **19**, 528).

L. K. CAMPBELL.

Physico-chemical aspects of hemolysis. III. A further study of some of the factors involved. REED ROCKWOOD AND E. C. MASON. *J. Lab. Clin. Med.* **10**, 91, 24 (1925); cf. *C. A.* **19**, 317.—Hemolysis by hypotonic solns. is accompanied by swelling of the cell mass while hemolysis by alkali, complement and antioceptor, saponin and NaOH soln shows no change in the cell vol. Hemolysis by acid may or may not be accompanied by swelling. The cells have considerable buffer power, which is greatest at the extremes of acidity and alk. This suggests a combination of acid and alkali with an additional buffer substance in these parts of the range and it is suggested that this combination may play an important part in rendering the hemoglobin-stroma union unstable in these zones. Viscosity detns. on the components of the biologic hemolytic system show no significant change during hemolysis. The hemoglobin and agar mixt. shows a certain similarity to the corpuscles in their behavior toward acid and alkali. The discharge of pigment from the cell of the red beet under the influence of acid and alkali and salt is in many respects similar to the loss of hemoglobin from the red cell or from the hemoglobin-colloid complexus. L. K. CAMPBELL.

Uric acid levels in the blood of man and animals. A. T. WEATHERS AND H. C. SWEANEY. *J. Lab. Clin. Med.* **10**, 480-5(1925).—The Folin Wu test does not give results equal to the total amt. of uric acid in the blood. Folin's and Benedict's latest methods give the same results and each method gives a fairly accurate recovery of uric acid added to human and animal bloods. Polyphenols and amino acids in quantities double those found in normal blood do not make appreciable error in uric acid detns. by the Folin or the Benedict method. The normal level of uric acid in the blood should be raised from 1.3 mg. to 1.4 mg. per 100 cc. of blood. Uric acid content of bloods in all stages of tuberculosis is normal excepting a slight decrease in the far-advanced stages. L. K. CAMPBELL.

Observations on the relation of urinary p_{H} to salt and water metabolism in a case of nephrosis. M. B. COHEN. *J. Lab. Clin. Med.* **10**, 526-32(1925).—Record of the urinary vol., percent chloride output, urinary p_{H} , plasma chlorides and wt. were kept for 110 days in a case of nephrosis on a diet of 10 g. of NaCl daily. With a rise in wt. of patient there was a chloride retention, diminished H_2O output, and a heightened acidity of the urine. Administration of alkalis to render the urine neutral was accompanied by a sharp increase in the chloride output, and loss of edema. Administrations of KH_2PO_4 reversed the process and was followed by a gain in wt. L. K. C.

The chloride content of the blood in pernicious anemia. R. I. HADEN. *J. Lab. Clin. Med.* **10**, 557-61(1925).—The chloride detns. on 30 cases of pernicious and 20 cases of secondary anemia are reported. The whole blood chlorides are usually high in blood with a low cell vol. in both primary and secondary anemia. The plasma remains normal regardless of the cell vol. A few cases of primary anemia show a low chloride content. No patients with secondary anemia had low chlorides. There is no relation of the chloride level of the blood to the free HCl of the gastric juice or to the vol. index of the corpuscles. The total store of chlorides in patients with very low cell vol. is higher than normal since the blood vol. shows little variations from normal and the plasma chloride content is higher than whole blood. L. K. C.

An attempt to find an antipeptic enzyme in the blood. U. D. KEASER. *J. Lab. Clin. Med.* **10**, 787-93(1925).—The methods described in the literature demonstrating an antipepsin were used and found to be inaccurate. More accurate methods must

Arch. inn. Med. **11**, 561-6(1925).—The water test in a healthy individual leads to no changes in the blood. When the reticulo-endothelial system has been blocked by an injection of electrocollargol there is a decreased elimination of H_2O and an hydremia as shown by a decrease in hemoglobin content and refractometric index. In patients with a tendency to edema these changes are particularly marked. H. F. H.

Insulin and the glucosuria of pregnancy. H. ELIAS, J. GÜDEMANN AND R. ROUBITSCHKEK. *Wiener Arch. inn. Med.* **11**, 567-80(1925).—Small doses of insulin increase the blood sugar content in pregnant and non-pregnant women. Intravenous introduction of sugar increases the blood sugar content equally in pregnant and non-pregnant women but in pregnant women the threshold of elimination is lower. Alimentary hyperglucemia responds to insulin less readily in pregnant or menstruating women than normal women. HARRIET F. HOLMES

The trypsin flocculation reaction in serum in its biologic meaning. P. SAXI AND A. KELEN. *Wiener Arch. inn. Med.* **11**, 549-60(1925).—The trypsin flocculation method previously described (*C. A.* **18**, 3401) has been modified by adding tricesol instead of chloral hydrate to the trypsin soln. Normal sera give a ppt. at 1:300 or 1:800. In certain pathological conditions, particularly severe diabetes, flocculation took place at dilns. as high as 1:51,200. A high titer was noted in carcinoma, pregnancy, decompensated heart disease, tuberculosis and nephritis. The antitryptic titer was not affected by parenteral introduction of trypsin or of a protein. The antitryptic titer was lowered by ligation of the pancreatic duct or extirpation of the pancreas. Administration of trypsin by mouth increased the antitryptic titer and it was also increased after meals. The trypsin flocculation reaction, therefore, is brought about by trypsin in the intestinal canal. HARRIET F. HOLMES

Exchange between tissue and blood. I. The action of venesection on the gases of the blood and the acid-base equilibrium of the organism. G. ENDRES AND C. NEUHAUS. *Z. ges. expl. Med.* **47**, 585-605(1925).—After venesection the CO_2 tension and the CO_2 content of the blood and serum are lowered. Small and moderate losses of blood cause no change in the reaction of the blood, but large losses of blood cause in most cases a change of the reaction of the blood towards the side of acidity. Loss of blood up to 0.3% of the body weight is without noticeable effect on the acid base equilibrium of the blood. Venesection leads to a lowering of the O_2 content of the arterial blood but has no noticeable effect on O_2 saturation or O_2 pressure. Both the CO_2 - and the O_2 -binding power of the blood are reduced, and in one case only half as much CO_2 was brought from the tissues to the lungs after venesection. Even after small or moderate loss of blood the urine shows an increase in the percentage of total P, primary phosphates, total N, ammonia N, NH_3 and degree of acidity. There is a decrease of alveolar CO_2 tension at the same time. HARRIET F. HOLMES

Fat replacement of the glycogen in the liver as a cause of death. E. R. LACOUNT AND H. S. SINGER. *Arch. Pathol. Lab. Med.* **1**, 84-9(1926).—With an extensive replacement of the liver by fat in persons who drink heavily of alcoholic beverages, death may be entirely unexpected and abrupt and with few symptoms of illness. H. F. H.

Amyloidosis produced by injections of proteins. R. H. JAFFÉ. *Arch. Pathol. Lab. Med.* **1**, 25-36(1926).—Amyloidosis occurring in mice after long-continued intramuscular injections of nutrose or serum results from an acquired hypersensitiveness to the injected substance. An endothelial resorption of the amyloid finally takes place in the liver, even though the injections are continued. HARRIET F. HOLMES

The lipid ratio and the content of water of normal and neoplastic tissues. A. H. ROFFO. *Néoplasmes* **4**, 65-72(1925).—In mice the amt. of H_2O contained in grafted tumors is 3 times the amt. of H_2O in the rest of the mouse, and this is also the ratio of cholesterol content of tumor and mouse. The ratio of cholesterol to fatty acids is an index of the capacity for the absorption of H_2O . This ratio is much higher in tumor tissue than in the rest of the mouse, or in a normal mouse. HARRIET F. HOLMES

The chemotherapy of cancer. J. THOMAS. *Néoplasmes* **3**, 108-25(1924). A review. HARRIET F. HOLMES

The dependence of the rapidity of oxidation on changes of reaction. I. The influence of an acid diet. R. DÜRR. *Z. ges. expl. Med.* **47**, 721-33(1925).—If an individual is kept on an acid diet for a number of days, the degree of oxidation is increased to a max. of 14%. Disturbance of the acid-base equil. by an acid diet is indicated by a decrease of the pH of the urine and a decrease of alveolar CO_2 tension, as well as by an increased degree of ventilation of the lung. If NH_4Cl is added to the acid diet the degree of oxidation is decreased 3.5-12%. HARRIET F. HOLMES

The catalytic activity of tissues and fluids in normal and pathologic conditions. J. THOMAS. *Néoplasmes* **1**, 145-52(1922).—The catalase content of the tissues and

blood varies normally, not only with the species of animal and with the individual, but also with the physiol. condition of the individual. It is probable there is a physiol. catalytic activity as there is a physiol. leucocytosis. The catalase content of the tissues and blood of patients with diseases other than cancer shows considerable variation but is generally lowered in cachectic conditions. It is low in tuberculous and syphilitic patients. The catalase content of the tissues and blood is generally lowered in patients with cancer, but there is nothing characteristic about the reduction. Exts. of cancer tissue contain less catalase than certain normal tissue exts. and more than others. The blood of cancer patients is also poor in catalase, but no more so than the blood of patients with other diseases.

HARRIET F. HOLMES

Serological diagnosis of cancer, based on a study of the reducing power of serum. J. THOMAS AND BINETTI. *Néoplasmes* 1, 51-9(1922).—The reduction of methylene blue proceeds more rapidly in a mixt. of serum and cancer ext. when the serum has been taken from an individual having a cancer. A positive cancer reaction with this test may be of diagnostic value. There were 2 apparent exceptions. In a far advanced case of cancer with cachexia the reaction was negative and one individual with a cancer heredity but showing no sign of a tumor gave a positive reaction, indicating that enzymes may be present in the blood in such cases in advance of the appearance of a tumor.

HARRIET F. HOLMES

The effect of solutions of copper sulfate on ducks. C. T. HURST. *Arch. Pathol. Lab. Med.* 1, 201-12(1926).— CuSO_4 solns. produced pigmentation in the livers of ducks. This pigment was hemofuscin. Definite pigmentation was produced in one instance with a 1:500,000 diln. of the salt. Paling of the deep yellow color of the feet and legs of several ducks, together with the deepening of the yellow color of the abdominal fat, may indicate that the carotinoid pigment responsible for this coloration may also be influenced by an overdose of CuSO_4 . It is probable that CuSO_4 would present only negligible dangers if used as anthelmintic for ducks and fowls provided its concn. does not go above 100 mg. per liter and if it is not used continuously. H. F. H.

A growth-promoting factor in tumor tissue. H. CHAMBERS AND G. M. SCOTT. *Brit. J. Exptl. Pathol.* 7, 33-40(1926).—A substance is produced from tumor cells during autolysis which *in vivo* causes an appreciable increase in the rate of tumor growth. It is a fairly stable chemical substance which is apparently derived from the nuclear structures.

HARRIET F. HOLMES

The action of calcium in man. II. The effect of calcium salts on the elimination of nitrogen in healthy individuals and in individuals with diseased kidneys. E. BARATH AND T. V. GYURKOVICH. *Z. ges. exptl. Med.* 47, 741-4(1925).—Ca salts, given intravenously or by mouth, caused a marked diminution in N elimination in the urine, both in healthy individuals and in individuals with kidney disease. Proteins are eliminated in decreased amount while Ca is administered. This may be due to an effect of the Ca salts on the permeability of the blood vessels of the kidney or to a decreased N metabolism.

HARRIET F. HOLMES

The behavior to nuclear staining of the erythrocytes of guinea pigs poisoned with lead. K. VORT AND G. ROESE. *Z. ges. exptl. Med.* 47, 734-40(1925).—The basophile granules and the polychromatic erythrocytes of guinea pigs poisoned with Pb give no nuclear stain, indicating an absence of a nucleic acid of the nature of thymonucleic acid. The basophile granules, therefore, have no genetic relation with the basophile nuclear substance of the cell nuclei. The nuclei of the normoblasts give the nuclear stain.

HARRIET F. HOLMES

Intercellular substances in experimental scorbutus. S. B. WOLBACH AND P. R. HOWE. *Arch. Pathol. Lab. Med.* 1, 1-24(1926).—Scorbutus is due to an inability of the supporting tissues to produce and maintain intercellular substances. The failure of cells to produce intercellular substance in scorbutus is due to the absence of an agent common to all supporting tissues which is responsible for the setting or jelling of a liquid product. Antiscorbutic substance is liberated in the destruction of tissues. Osteoblasts, in spite of great change in morphology, preserve their chem. potentialities and produce bone matrix.

HARRIET F. HOLMES

The importance of the phenomena of oxidation and reduction in the origin of cancer: a new hypothesis and arguments in its favor. J. THOMAS AND R. FIALIP. *Néoplasmes* 4, 73-9(1925).—Clinical study and chem. analysis of tissues and blood both indicate that cancer is the result of a disturbance of equil. between the oxidizing and reducing ability of the cells. There may be a disappearance from the nucleus of an oxidizing metal, as Mn, Mg, Fe or Cu, or its replacement by an inert metal incapable of acting as an oxidizing agent, as K or Zn. The production of cancer may be due to a decrease in oxidizing power or an increase in reducing power of the cell. H. F. H.

Urobilinemia. M. WINTERNITZ. *Z. ges. expl. Med.* **47**, 634-51(1925).—Urobilinemia is a frequent symptom of severe general infections and cardiac decompensation and is found in certain diseases of the liver and in the moribund. The urobilin contained in the serum is always enterogenous in origin, and its increase in the serum depends on a disturbance in the function of the reticulo-endothelial app. H. F. H.

A test of the function of the reticulo-endothelial apparatus. H. ADLER AND F. REIMAN. *Z. ges. expl. Med.* **47**, 617-33(1925).—Colorimetric detns. of the color index of the blood serum, made 4 min. and 1 hr. after intravenous injection of 10-12 cc. of a 1% Congo-red soln., gave an indication of the efficiency of the reticulo-endothelial app. of the organism. Septic infections, liver and circulatory disturbances, and extirpation of the spleen led to a rise in color index. The marked parallelism of the height of the Congo red index and the occurrence of urobilinemia indicate a relationship in the 2 conditions
HARRIET F. HOLMES

Diastatic activity in blood and urine. C. REID. *Brit. J. Exptl. Pathol.* **6**, 314-26(1925).—It is advisable to est. the blood diastatic activity in all cases where the urine diastatic activity is being examd. and especially in those cases which give a urinary diastatic figure toward the lower limits of normality. It would appear that the diastatic concn. factor would serve as an additional confirmatory test to MacLean's urea concn. test, as the figures obtained in both tests in healthy and pathol. cases were in general agreement.
HARRIET F. HOLMES

Ammonia in the blood of epileptics. J. M. LUCK, G. THACKER AND J. MARRACK. *Brit. J. Exptl. Pathol.* **6**, 276-9(1925).—High blood NH_3 occurs at times in epileptics, but not invariably before epileptic fits, and cannot be considered as the cause of the fits. An increase of blood ammonia is found in ketosis, whether occurring in starvation or in diabetes mellitus.
HARRIET F. HOLMES

A physico-chemical study of the serum of cancer patients subjected to an ultra-penetrating radio-therapy. A. H. ROFFO AND J. CORREA. *Neoplasmes* **3**, 211-24(1924).—Various physico-chem. tests were made on the serum of cancer patients before and after deep irradiation. In all cases after irradiation the surface tension and viscosity were increased, while the density, sp. cond. and p_H values showed no regular alterations in either direction.
HARRIET F. HOLMES

Free hydrochloric acid in the gastric juice in cancer patients. A. ROBIN. *Neoplasmes* **3**, 145-54(1924).—While free HCl is usually absent from the stomach content in cases of cancer of the stomach, this is not the absolute rule. Free HCl may be found in 10-25% of cases of cancer of the stomach and may be absent in a number of non-cancerous conditions as chronic gastritis. The absence of HCl is not to be attributed to a sp. action of the cancer on the secretion of HCl but may be due to chronic gastritis present. In cases where there is a normal secretion of HCl there may be little free HCl, due to a satn. with alk. bases coming directly from an ulcerating cancer or with albuminoids produced from the cancer tissue by peptic or peptolytic enzymes.
HARRIET F. HOLMES

The density of the blood. A. ROBIN. *Neoplasmes* **3**, 49-53(1924).—In general, the density of the blood is diminished in cancer patients. The lowered density is not, however, necessarily accompanied by a lessened hemoglobin content and a lowered blood count. The cases in cancer patients of an increased density of the blood are accompanied by an evident diminution in the activity of the glucolytic enzyme. The diminution in the density of the blood is less marked in sarcoma than in epithelioma.
HARRIET F. HOLMES

Refractometric study of the serum of cancer patients. A. KNIPFER. *Neoplasmes* **1**, 177-87(1922).—The refractometric methods of Freud-Kaminer and of Abderhalden may give values with normal serum of the order of +40: +10 and with serum from cancer patients an inverse ratio of +10: +30. Normal serum loses refractometric power on irradiation while serum from cancer patients on irradiation has its refractometric power augmented. Application of both refractometric tests before and after irradiation may prove of diagnostic value in cases of suspected cancer. H. F. H.

The influence of the ions $\text{Rb-SeO}_4\text{-SeO}_4$ on the respiration of normal and neoplastic cells. A. H. ROFFO AND S. M. NEUSCHLOSS. *Neoplasmes* **3**, 223-30(1924); cf. *C. A.* **19**, 2240.—Expts. *in vitro* and *in vivo* with rats indicate that Se and Rb salts cause a diminution of cell respiration in neoplastic and embryonal tissues as compared with normal and adult tissues.
HARRIET F. HOLMES

Glucolytic activation by tumor extracts. N. WATERMAN. *Brit. J. Exptl. Pathol.* **6**, 300-11(1925).—It is possible to increase the glucolytic activity of normal tissue by addn. of tumor ext. The activator substance present in tumor is not specific, as it

also contained in embryonic and to a lesser degree in normal tissue. The different behavior of the tumor-cell towards sugar utilization seems to depend only on quantitative differences caused by the presence of a much larger amt. of activator. Regarding the nature of the activator, some properties seem to point to an analogy with an insulin-like substance (cf. *C. A.* 19, 1737).

HARRIET F. HOLMES

The so-called reversion of hemolysis. I. The conditions of reaction for the change of the lake color of hypotonic hemolyzed blood to cover color with simultaneous reappearance of red blood cells in the microscopic field of vision. W. STARLINGER. *Z. ges. expl. Med.* 47, 406-19(1925); cf. *C. A.* 19, 1737 — Red blood corpuscles, hemolyzed by hypotonic solns., under certain conditions take up again hemoglobin from the laked soln. This so-called reversion of hemolysis is dependent on the kind and concn. of the blood used and the kind and concn. of the substance added. Reversion of hemolysis is brought about by neutral salts, heavy metal salts, HCl, NaOH and glucose, while urea, suspensions of lipoids and proteins are without effect. The H-ion concn. is of importance, as the neutral salts react less strongly on the reversion in a $p_{H} = 7$ than in a more acid or alk. medium. The reaction is more pronounced the lower the temp. **II. The nature of the course of the reaction.** W. STARLINGER. *Ibid* 420-33 — The so-called reversion of hemolysis seems to be due in part to an osmotic shrinking of greatly swollen, incompletely dissolved blood cells, and in part to a true return to the stroma of hemoglobin that had gone into solution. **III. A method of determination of the amount of hemoglobin that did not go into solution at first as well as of the amount that later was bound again to the stroma.** W. STARLINGER AND U. STRASSER. *Ibid* 434-46 — Native or citrated blood is suspended in its own plasma or in 0.9% NaCl. After centrifuging, the blood cells are dissolved in 9 parts distd. H_2O for at least an hr. 0.2 cc. of the blood soln. is mixed with 0.3 cc. distd. H_2O and 0.5 cc. 0.1 N HCl, and after a few min. 4 cc. 96% alc. are added. To 1 cc. of the soln. is added 1.0 cc. H_2O and to another cc. 1.0 cc. 0.308 mol NaCl soln. After centrifuging for an hour 0.5 cc. of the fluid is mixed with 0.5 cc. 0.1 N₂HCl and 4.0 cc. 96% alc. and the values obtained in an Authenreth colorimeter are compared with that of a standard soln. **IV. Some preliminary clinical findings.** W. STARLINGER AND U. STRASSER. *Ibid* 447-53 — A quant. study of hemolysis and its reversion in 50 normal and pathol. conditions showed that it gives an indication of the colloid chem. condition of the erythrocytes which is of no little importance if it is recognized that there are definite relations between the functional quantity and quality of red blood cells and their physico-chem. structure.

HARRIET F. HOLMES

Blood sugar in pernicious anemia. E. MEULENGRACHT AND POUL IVERSON. *Deut. Arch. klin. Med.* 148, 19(1925) — Two hundred and fifty detms. showed moderate increases in the blood sugar content accompanying pernicious anemia. The authors find no relation between blood sugar content and hemoglobin content or temp.; in this regard they fail to confirm the observation of Johansson (*C. A.* 17, 2317). The blood sugar curve in the acute periods may be raised or lengthened; these deviations result not from the anemic condition, but from the accompanying intoxication.

P. Y. JACKSON

The differential diagnosis of diabetes mellitus and glucosuria innocens. E. KULCKE. *Deut. Arch. klin. Med.* 148, 262-72(1925) — The blood-sugar curve after (1) feeding glucose, (2) injecting glucose and (3) injecting insulin, and the sugar content of the urine after the injection of insulin, do not strictly distinguish the 2 diseases. A case is discussed in which the blood sugar curve indicated diabetes after feeding carbohydrate, but harmless glucosuria after the injection of carbohydrate. P. Y. J.

The diazo and urochromogen reactions in the blood filtrate in kidney insufficiency; their explanation and clinical importance. E. BECHER. *Deut. Arch. klin. Med.* 148, 10-19(1925). — The blood serum, rendered protein free by pptn. with CCl_3COOH , gives a distinct yellow-brown diazo color-reaction in case of severe kidney insufficiency. NaOH was used instead of NH_4 , since the latter gave a slight color in a blank test; the other reagents were the usual ones for the test on urine. The filtrate from normal blood gives only a yellow test, due apparently to tyrosine and histidine. Acidification removes the color from a normal sample, but not from the pathol. one. In the latter case the color may be partly ascribed to aromatic oxacids, mono- and diphenols are not involved.

P. Y. JACKSON

Chromogens in the blood serum and in the urine in kidney disease; the origin of the bright color of the urine in atrophied kidney. E. BECHER. *Deut. Arch. klin. Med.* 148, 46-57(1925). — Blood and urine contain urochromogens and other chromogens, apparently tryptophan derivs.; tissue exts. also contain chromogens. Their appearance in the blood accompanies retention of indican, phenol, *p*-cresol, diphenols and aromatic

oxyacids. These are oxidized in the kidneys to the corresponding colored substances and eliminated as such.

P. V. JACKSON

Clinical observations on the physiology and pathology of the stomach secretions. LUDWIG HEILMEYER. *Deut. Arch. klin. Med.* **148**, 273-312(1925).—After stimulation with a 5% soln. of alc. contg. indigo carmin, the stomach juices of healthy persons contain 0.2-0.4% HCl; in true hyperacidity, over 0.5%; and in hypoacidity, 0.1% or less. The detns. were made as follows: A mixt. of 350 cc. H₂O, 18 cc. 96% alc. and 3 cc. of a 0.5% soln. of the dye is introduced into the stomach, mixed with the stomach contents, and every 10 min. a sample withdrawn for colorimetric detn.; the detn. is made rapidly as acid acts upon the dye. While the HCl concn. in an individual varies during the period of secretion, the total chloride is more nearly const. In pathol. cases showing no free HCl, or even an alk. juice, the Cl content is normal. Achyliaes secrete a juice of normal Cl content; but both the p_H of the urine and the CO₂ pressure of the alveolar air indicate that no acid is present and subsequently neutralized. Apparently secretion of Cl-ion and of HCl are independent; the latter requires more energy, is more easily disturbed by nervous impulses, and is especially more dependent upon the intensity of the stimulation.

P. V. JACKSON

The pathogenetic relations between true uremia, and the substances retained in the blood in cases of kidney insufficiency. E. BECHER AND F. KOCH. *Deut. Arch. klin. Med.* **148**, 78-85(1925).—The true symptoms of uremia vary widely with the blood content of phenol, cresol, diphenols and aromatic oxyacids; and are less closely related to the presence of intermediate decompn. products of proteins. This agrees with the observation that the symptoms of chronic phenol poisoning resemble those of true uremia.

P. V. JACKSON

The xanthoproteic reaction in protein-free blood in normal and pathological conditions. E. BECHER. *Deut. Arch. klin. Med.* **148**, 159-82(1925).—Normal whole blood and serum give a xanthoproteic reaction of the same intensity, detd. colorimetrically by comparison with a standard dichromate soln., the color in the serum being due to tyrosine and tryptophan. In kidney insufficiency the serum gives a higher value than whole blood; *p*-cresol, phenol, aromatic hydroxy acids and small amts of indican and diphenols are present. Extn. with ether, after hydrolysis, removes phenolic substances and reduces the intensity of the reaction. In severe kidney insufficiency the intensity is reduced by extn. with ether without previous hydrolysis, due to the removal of free aromatic hydroxy acids. Phenylalanine and other phenyl derivs. give a weaker reaction than do tryptophan, tyrosine, and other phenol and indole derivs. In acid soln. tyrosine shows less effect than tryptophan or indican; in alk. soln. this condition is reversed. Expts. are tabulated giving the comparative colorimetric values of other related substances, as indican, pyrocatechol, salicylic acid, adrenaline, etc.

P. V. JACKSON

Clinical, experimental, and histological investigation of the poisoning of the stomach by acids. K. SICK. *Deut. Arch. klin. Med.* **148**, 318-43(1925).—Observations on a number of hospital cases and on cats, of the anatomical and functional results of mineral acids taken through the mouth.

P. V. JACKSON

Disturbance of the physico-chemical equilibrium of the skin by making it acid or alkaline. FRANZ WIRZ. *Krankheitsforschung* **2**, 186-94(1926).—The hands and arms of the subject are placed in a galvanic bath at body temp.; the current enters by the skin of one arm, passes through the body, and leaves by the other arm. With normal individuals the skin of the anode-arm, in which there are an excess of anions, shows after about 12 min., with a current of 10 milliamps., small bright-red spots, which increase in size until all the immersed skin is red; the color disappears in a few hrs. after the end of the expt. On the cathode side after about 17 min. exposure, the skin begins to turn grayish or livid. In 100 different persons the results differed only in intensity. The acid-reddening is arterial, and corresponds to active hyperemia; the alkali-color is venous, and corresponds to passive erythemia. If the skin is exposed to bright sunlight, producing erythema before exposure to the current, the acid-arm is more inflamed, while inflammation is retarded and is less intense in the other arm. W. recognizes the acidification or alkalization of the tissue as a sp. causative factor in many skin diseases.

P. V. JACKSON

Experimental investigation of inflammation. HERMANN GROLL. I. The influence of acid and alkali upon the migration of leucocytes. L. SIEGEL. *Krankheitsforsch.* **1**, 59-65(1925).—The web of each hind foot of a frog is punctured, touched with 2% AgNO₃, and washed with water; water is then dripped upon one leg, and 0.01% HOAc, or 0.001% lactic acid upon the other. The degree of inflammation and the no. of leucocytes found in the tissue seemed not to be affected by the use of acid rather than

water, except where the acid was strong enough to exert a destructive effect of its own. When a current of 7–12 milliamp. is sent through the body of rats or guinea pigs, whose skin has been previously irritated with turpentine, no difference is observed in the no. of leucocytes in the tissues around the anode and cathode. **II. Further investigation of the action of acid and alkali upon the living organism.** HERMANN GROLL, *Ibid* 66–9.—A small current passed through both hind legs of a frog, previously injected with acid fuchsin or other dye, causes the skin of the acid leg to assume the acid color of the dye. Circulation ceases in the skin of both legs, and in the anode leg does not resume upon cessation of the current. Apparently an excess of OH-ions has less harmful effect than an excess of H-ions. This is also true in the muscles. **III. The oxygen-respiration of surviving kidney tissue, with special attention to alterations in the tissue.** HERMANN GROLL AND ILSE SCHIEFERDECKER, *Ibid* 2, 195–219(1926).—The O₂ consumption is detd. thus: A small piece of the surviving tissue is shaken in Ringer soln. satd. with O₂ in a closed vessel contg. air, at 37.5°; the change in pressure is followed with a manometer. For normal kidney tissue the value detd. ranges from 13.20 to 20.05, averaging 15.02 for 1.5 hrs.; these values represent cm. O₂ absorbed/(mg. tissue × hrs.). After HgCl₂ poisoning the normal values were found, except where the tissue showed fatty deposition and advanced necrosis; then the value was lower. In salicylate poisoning the rate of respiration falls much more rapidly with time than for normal tissue, though no morphological changes are visible microscopically. **IV. The effect of inflammation and of irritation on the rate of oxygen-respiration of tissues.** G. BORGER AND H. GROLL, *Ibid* 2, 220–62.—When one ear of a mouse is painted with croton oil, the rate of O₂-absorption is found first to rise sharply and then to sink below the value for the other ear; and to cease entirely after 24–36 hrs. When painted with 6% diphenylarsine chloride in petroleum ether, respiration ceased within 8 hrs.; with concd. formic acid, almost at once. One percent papain and tincture of cantharides increased the rate. The increase was the same whether the irritant was applied before or after cutting off the ears, so the change is not a secondary one due to hyperemia. P. Y. JACKSON

The cholesterol content of the blood serum in pernicious anemia. HERMANN KÖHN, *Deut. Arch. klin. Med.* 148, 357–71(1925).—The method of Autenrieth and Funk was used to det. cholesterol. In all cases of pernicious anemia there was a decrease in the cholesterol content, greater or less according to the stage of the disease. K. believes that hypocholesterolemia is directly proportional to the degree of toxicity produced by the disease in each stage. New researches are needed to clear up the question of cholesterol metabolism in pernicious anemia. P. Y. JACKSON

The sugar and calcium content of the cerebrospinal fluid. K. BRUCKE, *Deut. Arch. klin. Med.* 148, 183–94(1925).—B. confirms the conclusion of Leicher that the Ca content is very nearly const. in normal adults, and does not vary even with diseases of the central nervous system. B. noted a lowering of the sugar content in some cases of meningitis, and in progressive paralysis, an increase in epilepsy, and normal values for cerebrospinal syphilis. The const. value for Ca can be explained only by the active selective ability of the chorioid plexus, but whether this selectivity is resorptive or secretory is not detd. The results of numerous analyses are given in tabular form. P. Y. JACKSON

Disturbance of carbohydrate metabolism in pregnancy. O. KLEIN AND E. RIS CHAWY, *Deut. Arch. klin. Med.* 148, 195–213(1925).—Diabetes of pregnancy has been ascribed to renal disturbance, to failure of the liver to build up glycogen, and to disturbance of the glands of internal secretion. K. and R. investigated a case which showed blood sugar subnormal; after feeding glucose in 3–20 g. portions at 30 min. intervals, the blood sugar at first rose with each portion higher than for a normal person, but fell much more quickly to its subnormal level than in true diabetes. Levulose fed in the same way caused a pronounced decrease in sugar in both blood and urine, there was no levulosuria. The glucosuria observed did not correspond to the glucose intake, nor did it increase with a heavy protein diet. The usual symptoms of pancreatic diabetes were absent. The injection of 60 units of insulin, incompletely compensated by 70 g. of white bread 30 min. later, was followed in 2.5 hrs. by a rise in blood sugar from 0.089 to 0.162, an increase of 100%, while more than 4 hrs. were required for a return to the original value. Both serum protein and the no. of erythrocytes decreased with insulin injection. A control expt. without insulin showed about the same increase in blood sugar, and the same rate of elimination in the urine. The authors conclude that the abnormal carbohydrate metabolism in pregnancy results from disturbance of the glands of internal secretion. P. Y. JACKSON

Determination of variations in the acid content of the blood. KL. GOLLWITZER-

MRIER. *Deut. Arch. klin. Med.* **149**, 151-6(1925).—An abnormal concn. of acid in the blood may be detd. by the degree of loss of ability to take up CO_2 , after making an allowance for any change in the total alkali content. In a case of diabetic coma with uncompensated acidosis ($p_{\text{H}} = 6.94$) about 0.02 mol. alkali was withdrawn by the blood to neutralize the ketonic substances present. This was calcd. by measuring the decrease in CO_2 tension, and the corresponding decrease in bicarbonate content. In Hg poisoning, when the blood contains large amts. of the products of decomp. proteins, there is a large decrease in the anion deficiency, showing the retention of acids; on the other hand, in a case of tetany of the stomach the CO_2 rose to 117 vol. %, due to the alkali freed by loss of Cl.

P. Y. JACKSON

The antigen properties of hemoglobin. W. ENGELHARDT. *Biochem. Z.* **163**, 187-96(1925).—Rabbits are immunized by injection of hemoglobin from dogs' blood, and the antigen properties of the rabbit serum are studied. In this serum is found an antibody which can bind hemoglobin. The method of prepn. of the hemoglobin is without influence upon its ability to react with immune serum, which is specific in its action.

W. D. L.

The oxidase nature of the leucocyte granules. A. NEUMANN. *Folia Hematol.* **32**, 95-6(1925).—A defence is made of the theory of the oxidase nature of leucocyte granules.

JOHN T. MYERS

The genesis of blood platelets in the light of the oxidase reaction. K. KATSUNUMA. *Folia Hematol.* **32**, 29-31(1925).—The granules in the cytoplasm of megakaryocytes and blood platelets both give the oxidase reaction, which supports the theory that blood platelets arise from the cytoplasm of megakaryocytes.

JOHN T. MYERS

Experimental production of vituline fever. L. AUGER. *Compt. rend.* **182**, 348-50(1926).—Injection of insulin in the healthy cow produced symptoms like those of collapse in vituline fever. Instead of the usual injection of air into the udder, a subcutaneous injection of 40 g. of glucose in 20% soln. gave rapid relief.

L. W. RIGGS

Urinary calculi. Chemical composition and structure in relation to radiography. D. E. SHEA. *J. Am. Med. Assoc.* **85**, 1939-43(1925).—The relative opacity of a urinary calculus depends on the total mol. or at. wts. of its constituents and is influenced by its structure and thickness. Some urinary calculi having constituents of low at. wt. are negative to the Röntgen ray. These include stones composed of uric acid, urates and triple phosphate. The diagnosis of urinary calculi should not be guided entirely by radiographic reports.

L. W. RIGGS

The influence of nutrition on the growth of mouse carcinomas and rat sarcomas. F. LUDWIG. *Z. Krebsforsch.* **23**, 1-8(1926); cf. *C. A.* **19**, 2842.—Rats and mice kept on a vitamin-free diet as long as possible and then inoculated with malignant tumors either failed to develop these tumors or outlived control animals, all of which developed tumors. The animals were given vitamins when it became necessary to keep them alive. It is suggested that the fact that cancer appears mostly in old age is because in the actively growing periods of life the necessary vitamins are used by the normal growing tissues and only after cessation of body growth is there a surplus supply of vitamins available for tumor growth.

H. G. WELLS

The cytolytic action of selenium and its compounds. A. H. ROFFO AND L. M. CORREA. *Z. Krebsforsch.* **23**, 82-4(1926).—The effect of various Se compds. was tried on spindle cell sarcoma of the rat and normal rat liver cells. The tumor cells were much more sensitive to the lytic action of the selenium salts than were the normal cells. Sarcoma cells were not compared with normal connective tissue cells.

H. G. WELLS

The growth of normal and malignant tissue cells under increased oxygen pressure. A. FISCHER AND E. B. ANDERSEN. *Z. Krebsforsch.* **23**, 12-27(1926).—Under increased O tension, sarcoma cells are killed more quickly than normal tissue cells in artificial cultures. It was found possible, by using suitable O tension, to transform mixed cultures of normal fibroblasts and sarcoma cells into pure cultures of connective tissue.

H. G. WELLS

Anaphylactic shock caused by antibody in animals sensitized by antigen. Reversed passive anaphylaxis. E. L. OPIE AND J. FURTH. *J. Exptl. Med.* **43**, 469-82(1926).—Anaphylactic shock occurs (in rabbits) when the usual procedure for the production of passive anaphylaxis is reversed; that is, when an animal previously treated with an antigen receives the corresponding antiserum by way of the circulating blood. This susceptibility to the action of anti-horse serum produced by injection of antigen reaches a max. intensity after an interval of 4 hrs. presumably required to permit penetration of the antigen in sufficient concn. into the tissues. Desensitization to the action of a shock-producing dose of anti-horse serum can be brought about by repeated small

doses of the same antiserum. Anaphylactic shock and local anaphylaxis manifested by the acute inflammation of an immunized animal when injected with the antigen used for immunization (Arthus phenomenon) occurs under analogous conditions; that is, when antigen and antibody meet within the tissues. The peculiar characters of these reactions are dependent upon the site of entry of the irritating agent, which is the vascular system in 1 instance and tissue space in the other, and upon the concn. of antigen and antibody within susceptible tissues. Meeting of antigen and antibody within susceptible tissues is sufficient to explain the phenomena of local and general anaphylaxis so that it is unnecessary to assume the sudden formation of a toxic substance (anaphylatoxin).

Reaction of cow milk to blood serum precipitin. P. S. JONES AND C. J. WEST. *J. Exptl. Med.* **43**, 451-9 (1926).—Normal milk when tested with units of sp. blood serum precipitin which will detect 1/40,960 cc. of cow serum will react in dilns. of 1:80 and 1:160 and in some cases, at even higher dilns. Milk withdrawn from the udder at the end of milking is not richer in blood protein than that obtained at first. The udder fluid just before parturition is rich in serum proteins, their concn. within the udder is temporary; at first they diminish rapidly as soon as the udder is regularly emptied and then fall gradually to the normal level. Even in milder cases of mastitis there is a considerable increase in the serum content of milk from the affected quarter. As the process becomes more severe serum passes into the udder to a greater degree but the increase is confined only to the involved quarter. The addn. of even as little as 1:80 part of mastitis milk to bottled milk will increase the serum titer 4 to 8 fold. Milk heated to a temp. as high as 66° for 20 min. will react at the same dilns. as the raw milk. Milk pasteurized at 68-9° for 20 min. will no longer react. The precipitin test then affords a ready means of detecting milk heated above 68-9°.

Effect of antiserum against the soluble toxic substance of *Bacillus coli* in *Bacillus coli* peritonitis. BERNHARD STEINBERG AND E. E. ECKER. *J. Exptl. Med.* **43**, 443-50 (1926).—From young cultures of *B. coli* (18 to 24 hrs.) a sol. toxic substance was obtained and an antiserum against this toxic substance was produced. The sol. toxic substance is the principal lethal factor when cultures of *B. coli* are injected into the peritoneal cavity of rabbits. Intravenous administration of the antiserum can avert death in rabbits previously injected intraperitoneally with lethal doses of *B. coli*.

Effect of jejunostomy in experimental obstruction of the jejunum of the dog. R. L. HADEN AND T. G. ORR. *J. Exptl. Med.* **43**, 183-93 (1926).—Jejunostomy does not prevent the development of the chem. changes of the blood characteristic of obstruction of the jejunum in the dog. Treatment of jejunal obstruction with NaCl soln. tends to prolong the life of animals regardless of jejunostomy.

Experimental bone marrow reactions. I. Anemia produced by collargol. G. L. MÜLLER. *J. Exptl. Med.* **43**, 533-53 (1926).—The effect produced by the intravenous administration of collargol on the bone marrow of rabbits varies directly with the amt. of collargol injected; 3 fairly well defined stages are recognized. There was no evidence of injury to blood cells in the peripheral circulation. The erythrocytic bone marrow aplasia was present before any appreciable decrease of red blood cells was found in the peripheral blood. The results were less clear cut in a series of rats, but anemia of a similar type was produced in all animals when sufficiently large doses were injected. Splenectomy did not alter the course in rats materially. The cause of the anemia may be sought in the deviation of the parental endothelial cell towards clastocyte formation at the expense of the development of erythrocytes.

PETERS, JOHN P. AND VAN SLYKE, DONALD D. **Quantitative Chemistry in Clinical Medicine.** Baltimore: The Williams & Wilkins Co.

H PHARMACOLOGY

ALFRED N. RICHARDS

The individual sensitivity of rabbits toward insulin. E. LAQUEUR AND S. E. DE JONGH. *Biochem. Z.* **163**, 308-37 (1925). There is an intra and an inter-individual variation in the response of rabbits to insulin. Climate is responsible for some of these variations. **Determination of the active strength of insulin and the new clinical unit.** E. LAQUEUR AND S. E. DE JONGH. *Ibid.* 338-43.—The method used for assay of an insulin prepn. is described. **Relation between dose and blood sugar lowering (concentration-activity curve) and swelling value of insulin.** E. LAQUEUR AND S. E. DE JONGH. *Ibid.* 344-55.—By the swelling value of insulin is meant the smallest dose which will in 2 hrs. produce a lowering of the blood sugar of 0.06 to 0.15 mg. cc. For rabbits, it

is about 0.1 unit. It may vary as much as 400% for humans, and so must be detd. for each individual. **Influence of carbohydrates, fats, and protein upon the sensitivity toward insulin.** A. GREVENSTUK, S. E. DEJONGH AND F. LAQUEUR. *Ibid* 355-70.—See C. A. 19, 3538. **Influence of the degree of purity upon the activity of insulin.** S. E. DEJONGH AND F. LAQUEUR. *Ibid* 371-80.—See C. A. 19, 3538. **Giving of insulin by means other than by subcutaneous or intravenous injection.** S. E. DEJONGH, E. LAQUEUR AND K. NEHRING. *Ibid* 381-9.—Insulin given by enteral, rectal, vaginal or nasal routes is not absorbed, but given percutaneously in salves it is absorbed. The last method is being studied for its clinical application. **The glycogen content of the liver of rabbits with insulin, especially with the detachable abdominal window.** A. GREVENSTUK AND F. LAQUEUR. *Ibid* 390-402.—The technic whereby successive portions of the liver of rabbits may be removed for the detn. of glycogen enables the effect of insulin upon liver glycogen to be detd. Insulin seems to have no definite influence upon liver glycogen, probably because the error of the detn. is so large. **Influence of glycogen and starch injections upon the cramps of insulin rabbits.** S. E. DEJONGH AND F. LAQUEUR. *Ibid* 403-5.—Intravenous injection of glycogen or sol. starch can relieve insulin convulsions in rabbits. **Influence of intravenous injection of glycogen and starch upon the blood sugar of rabbits.** F. LIPMANN AND J. PLANELLES. *Ibid* 406-11.—The ability of blood diastase to hydrolyze glycogen is dependent largely upon the degree of purity of the glycogen. Intravenous injection of sol. starch or glycogen produces a rise in blood sugar lasting for 3 hrs. W. D. L.

Insulin and the blood-fat. A. C. WHITE. *Biochem. J.* 19, 921-6(1925).—The marked hypoglycemia caused by insulin in the normal dog is accompanied by an increase in the blood-fat, the fatty acid being affected more than the cholesterol.

BENJAMIN HARROW

Insulin and glucose utilization: effects of anesthetics and pituitrin. C. G. LAMBIE. *Brit. J. Exptl. Pathol.* 7, 22-32(1926).—The av. rate at which the tissues remove glucose from the circulation in the decerebrate cat with the liver tied off is 0.15 g. per kg. per hour. This rate is increased by 75 to 100% by insulin in doses of 10 units per kg. When the liver is included and the splanchnics are cut, the rate of removal averages 0.6 g. per kg. per hr. The rate at which the tissues remove glucose from the circulation when the liver is excluded is about the same under anesthesia as in the decerebrate prepn. The rate at which insulin accelerates the removal of glucose appears to be unchanged by the administration of anesthetics. Doses of pituitrin which are sufficient to prevent the fall in blood sugar under insulin in the intact animal fail to do so when the liver is excluded, and glucose is supplied at the rate necessary to keep the blood sugar level during the control period.

HARRIET F. HOLMES

The antagonism between adrenaline and insulin with regard to the autonomous nervous system. V. KOGAN AND N. PONIROWSKY. *Z. ges. exptl. Med.* 47, 557-671(1925).—Insulin and adrenaline are antagonistic in their behavior towards the autonomous nervous system.

HARRIET F. HOLMES

The influence of insulin on the secretion of adrenaline by the adrenals. M. N. TSCHIBOKSAROFF AND Z. J. MALKIN. *Z. ges. exptl. Med.* 47, 580-4(1925).—The injection of insulin has a stimulating action on the process of excretion of adrenaline by the adrenals.

HARRIET F. HOLMES

Effect of Röntgen rays on the vegetative system. OTTO STRAUSS AND JULIUS RÖTHNER. *Strahlentherapie* 18, 37-63(1924); *Ber. ges. Physiol. exptl. Pharmacol.* 31, 486(1925).—Röntgen irradiation lowers the blood pressure of rabbits. This action has some relation to the sympathetic as it can be suppressed by atropine. Liver and pancreas irradiation increases the blood sugar; in the dog pancreas irradiation has the same effect. Isolated irradiation of the adrenals is followed a few days later by a decrease of blood sugar. Skin irradiation in man has no influence on glucemia.

MARY JACOBSEN

Thallium as a poison and a remedy. HUGO HARTNACK. *Berl. tierärztl. Wochsch.* 41, 49-51(1925); *Ber. ges. Physiol. exptl. Pharmacol.* 31, 633(1925).—A review.

I- ZOÖLOGY

R. A. GORTNER

Determination of water-soluble excretions of aquatic animals. EMIL LENK. *Biochem. Z.* **168**, 61-8 (1926).—Changes in elec. cond. of the water in which fish live are used to det. the elimination of H_2O -sol. waste products. The fish (*Phoxinus phoxinus*) begin to excrete about 2 hrs after feeding. Expts. at 10, 18, and 25 show that the metabolism and the rate of excretion both increase with the rise in temp. The temp. coeff. (van't Hoff's) varies from 1 to 1.44, and is greater at the higher exptl. temp. (10-20°, 1-1.21; 15-25°, 1.18-1.41). S. MORELLIS.

Cetacea. IX. Serological investigation of the relationship of different kinds of whales. NOBUYOSHI FUSE. *Japan J. Med. Sci.* **1**, Pt. II, 1-4 (1925).—Pptn. reaction and complement fixations indicate that the sperm whale, the finback and the "seiwal" are closely related. **X. Synovial liquid.** *Ibid.* 5-9.—The synovial fluid of the finback has a slightly alk. reaction and is very thick, though this property is lost on standing some time at room temp.; that from a head joint required 325 sec. to flow from a Redwood viscometer at 38° (50 cc. of H_2O required 25 1/2 sec.), d. 1.012, solid constituents, 2.45-2.55; ash, 0.96-1.00; total N, 0.2645-0.2896 (g. per 100 g. liquid), corresponding values for the liquid from a shoulder joint are .275 sec., 1.012-2.13, 0.93-1.01, 0.2110-0.3016. The liquid from the shoulder joint of a "seiwal" had d. 1.013, solids, 2.39, ash, 1.10. The liquid from the finback had a refractive index of head, 1.33797-1.33766; shoulder, 1.33820-1.33799. **XI. Physiological importance of the divisions of the whale stomach.** MAKI TAKATA. *Ibid.* 11-23, cf. *Ch. I* **16**, 3511. A study of the enzymes of the whale stomach indicates that the pepsin formation occurs in the 2nd stomach; lipase occurs in the mucous membrane of all 3 of the stomachs but is present in largest amts. in the 3rd stomach. The H_2O , Cl and Fe content of the mucous membrane showed the following variations in 4 animals: 2nd stomach, 79.6-84.7, 2.33-3.14; 0.026-0.040 (the last 2 are reported for the dry substance), 3rd stomach 85.5-88.7; 2.50-4.48; 0.022-0.041, duodenal ampulla, 83.1-86.3, 3.30-5.75, 0.011-0.026. The behavior on autolysis is also reported. **XII. Physicochemical properties of the "seiwal" urine.** SHIKANOSKE MORIMURA. *Ibid.* 25-7.—The limits observed in 7 samples of urine were, d. 1.023-1.034, freezing point lowering, 1.83-2.51, dec. cond. (K_{10}^0), 239.3-432.2, p_H (electrometric) 3.8-5.6, (thy. indicators) 5.5-6.5, relative surface tension, 92.2-97.9, stalagmometric quotient, 1.01-1.01. **XIII. Content of the cysts occurring in the spermatid duct. The liquid accumulation in the uterus.** KATSUMI OKAZAKI. *Ibid.* 29-30.—The cyst consists of a pale yellow, slightly turbid liquid of d. 1.010-1.015, it is slightly alk., lies between 7 and 8, analysis showed H_2O , 97.83%, solids, 2.17%, total N, 0.12, protein, 0.3, Et_2O -extractives 0.61; ash, 0.89. A non-pregnant uterus contains a nearly colorless liquid, which is slightly turbid, reacts slightly alk., d. about 1.030, freezing point lowering, 1.86°, ash 3.5-4%, of which about 0.5 is Cl. **XIV. The nature of ambergris and its constituents.** MAKOTO SUZUKI. *Ibid.* 31-42. Ambergris contains about 25% of ambrin (I), very small amts. of morg. compds., largely $Ca(PO_3)_2$ a porphyrin but principally a fat-like product which has not been investigated. I m. 83° [α_D^{20}] 20.5 (0.5 g. in 25 cc. 90% $EtOH$), contains 83.7% C and 12.1% H, mol. wt. in camphor, 340. Catalytic reduction caused the addn. of about 4 atoms of H, the reduced compd. m. 78-80°. I adds 86% Br. The behavior of I towards different cholesterol reagents is reported, which indicates that I is a sterol or a deriv. thereof. **XV. Composition of finback whale blood.** YOSHIO OKAHARA. *Ibid.* 43-7 (1925).—The dry matter of the blood is about 22 g. per 100 cc. blood, the total N 2.6 to 2.8 g. The urea N varies from 20 to 30 mg. for blood, 25 to 34 mg. for serum, the NH₄ N varies from 7 to 15 for blood, 3 to 4 mg. for serum, ammonia N, 0.5 to 0.9 mg. for blood, 0.9 to 0.12 for serum. The total fatty acids (mg. per 100 cc.) in the blood are about 545 for the serum, 662-825. The lecithin, 250-75, 370-120, cholesterol, free, 86, 21-30, combined, 48-53, 68-76. The blood sugar may vary from 0.0806 to 0.1604 g. per 100 cc. blood, and from 0.0532 to 0.1626 for serum. The inorg. constituents of the blood vary as follows in 4 samples: Na, 322-343 mg. per 100 cc.; K, 221-232; Mg, 4.6-6.6, Ca, 5.4-7.4, Cl, 8.7-50.7, H₂SO₄, 1.9-2.6; H₃PO₄, 30.6-40.3. **XVI. Whale flesh.** MAKOTO SUZUKI. *Ibid.* 49-50.—The "seiwal" flesh on the market contains 75% H_2O , the solid matter contains 3.4% N

The flesh, treated with Me_2CO at room temp., then extd. with EtOH and CHCl_3 , gave 6% of an ext., contg. 0.068 g. free and 0.004 g. combined cholesterol and 0.1 g. lecithin P_2 as P_2O_5 ; I no., 29.7; acid no., 65.2. An air-dried sample contained 4.5% Et_2O extractives, contg. 0.03 g. cholesterol. The dry material usually contained 15-20% H_2O , 10-15% N, 5-6% ash. The ash gave the following analysis (g. per 100 g. flesh): Cl, 0.57; P_2O_5 , 1.68; H_2SO_4 , 1.68; Na_2O , 0.42; K_2O , 0.94; CaO , 0.03; MgO , 0.13; Fe, 0.035. **XVII. Peritoneal fluid.** NOBUYOSHI FUSE. *Ibid* 51-3.—The peritoneal fluid of the finback whale is a brownish yellow fluid of sp. gr. 1.020, slightly alk. towards litmus, shows a f. p. lowering of 0.70° , contains 3.42 g. solid substance per 100 cc.; urea 0.006, NH_3 0.008, amino N 0.018, creatinine 0.01, uric acid trace, total N 0.542, non-protein N 0.75, sugar 0.065, Et_2O ext. 0.07, total ash 1.05, NaCl 0.8, H_2SO_4 0.02, H_3PO_4 0.08, K 0.03, Ca 0.01, Mg 0.006, Fe 0.0003. **XVIII. Sugar content of the blood.** YOSHIBUMI MASUMIZU. *Ibid* 55-60.—The various methods employed for detg. sugar gave fairly consistent results, indicating that the values really represent sugar. In the blood and serum of the finback whale the sugar varies from 0.205 to 0.364, 0.110 to 0.35; in the "seiwai" the values are from 0.065 to 0.262, 0.165 to 0.341 (only 2 samples of serum reported). **XIX. Composition of the tendons and sclera.** Preparation of *d*-aminobutyric acid from sclera. SHU OIKAWA. *Ibid* 61-7 (1925). The tendon of the sperm whale, air-dried, lost 23.2% of its wt. at 110° and contained 15% ash, the air-dried sample contained 14.28% total N. The fat-free sclera contained 13.4% H_2O , 0.7% ash and 12.30% total N. The total N of the tendon and sclera was divided as follows (% of the total): NH_3 , 5.53, 1.17, humin, 2.03, 0.89; mono- NH_2 , 69.75, 60.49; non- NH_2 , 3.08, 8.85; arginine, 6.44, 10.49; lysine, 7.49, 8.21; histidine, 2.24, 1.71; cystine, 3.01, 5.04. The hydrolysis of 200 g. sclera and 100 g. tendon gave the following amts. of NH_2 acids: glycocoll ester-HCl, 21.2 g., 18.5 g., alanine, 6.6 g., 5.7 g.; leucine, 2.9 g., 1.2 g.; proline, 1.6 g., 8.5 g.; glutamic acid-HCl, —, 2 g.; phenylalanine, 3.5 g., traces; *d*-aminobutyric acid, 4 g., —. This is the 1st time this acid has been definitely isolated from an acid hydrolysis of a protein. **XX. Composition of the urine of Delphinidae.** MAKOTO SUZUKI. *Ibid* 69-70.—Three samples are reported, one from "Grindwal" and 2 from porpoises; samples were collected 8 hrs. after death. Sp. gr. 1.032 at 11° , 1.052 at 22° , 1.038 at 20° ; f. p. lowering, 2.005, 3.408, 2.278; total N, 1.747, 2.974, 1.764; urea, 2.940, 5.250, 2.910; NH_3 , 0.17, 0.145, 0.091; creatinine, 0.162, 0.116, 0.156; creatine, 0.187, 0.148, 0.137; uric acid, 0.048, 0.036, 0.029; Cl, 0.653, 0.848, 0.606; Ca, —, —, 0.028; Mg, —, —, 0.025. **XXI. Enzymes of the pancreas.** MAKI TAKATA. *Ibid* 73-89.—Trypsin is present but amylase is nearly or completely absent. **XXII. Preliminary investigation of the articular cartilage of the whale.** SHU OIKAWA. *Ibid* 91-5(1925).—The cartilage contained 77.5% H_2O , 2.43% ash, 2.9% N, 1.9% total S, 1.4% SO_4 and 0.8% fat. Extn. with 0.1% HCl gave about 0.3 g. chondroitinsulfuric acid from 500 g. cartilage. About 35% of the total N is present as collagen, 7% as chondromucoid, 5% as albumoid, and 15% extractives. The chondromucoid was isolated and the protein component sepd. and its N partition detd. of the total N (12.39%) 1.05% is humin N, 48.75 mono- NH_2 , 15.90 non- NH_2 , 6.78 NH_3 , 18.64 arginine, 1.05 histidine, 5.25 lysine and 2.66 cystine. The gelatin after purification contained 1.17% ash, 0.47% S and 17.57% total N, distributed as follows: humin 0.06, mono- NH_2 53.78, non- NH_2 18.21, NH_3 1.94, arginine 12.86, histidine 2.62, lysine 7.29. **XXIII. Amniotic liquor of the sperm whale.** MAKOTO SUZUKI. *Ibid* 97-101(1925).—The amniotic liquor, collected 10 hrs. after the death of the whale, was pale yellow, slightly opalescent, d_{20} 1.013, freezing point, -0.577° , nearly neutral to litmus and showed the following analysis: H_2O , 96.11 g. per 100 cc.; dry substance, 3.89; total N, 0.216; protein according to Scherer, 0.043; by AcOH pptn., 0.028; urea, 0.064; NH_3 , 0.022; NH_2 N, 0.018; uric acid, 0.004; creatine, 0.014; creatinine, 0.016; fat, 0.011; cholesterol, present; fructose, 1.975; Cl, 0.122; H_2SO_4 , 0.055; P_2O_5 , 0.008; K_2O , 0.061; Na_2O , 0.078; CaO 0.046; MgO , 0.015; Fe, 0.0004. C. J. WEST

Blood of the seal. MAKOTO SUZUKI. *Japan. J. Med. Sci.* (Trans., II) 1, 71-2 (1925).—The blood of the seal has a hemoglobin value of 160 (Sahli), contains 81.7 mg. Fe per 100 cc. blood, has a sp. gr. at 18° of 1.069-1.073, shows a freezing point lowering of $0.70-0.72^\circ$ and contains 3.8501 g., total N per 100 cc. blood, divided as follows: residual 0.0800, urea 0.0187, NH_3 0.0125, NH_2 0.0243, creatinine 0.0028, uric acid 0.0082; Cl, 0.3440; Na and K as chlorides, 0.8420. C. J. WEST

Comparative biochemistry of urine. NOBUYOSHI FUSE. *Japan. J. Med. Sci.* (Trans., II) 1, 103-10(1925).—In a series of 17 tables, F. gives the compn. of the urines from the weasel, racoon, tiger, leopard, hyena, bat and python, including the total N, urea, NH_3 , NH_2 N by formol titration, creatine and creatinine, uric acid, purine N

and allantoin, total S, total and ethereal H_2SO_4 , P, ash, sp gr etc For most of the animals several samples are reported.

Developments in pest destruction with hydrocyanic acid. WALTHER HERZOG *Oesterr. Chem.-Ztg.* 29, 27-8(1926).—Tin cans filled with diatomaceous earth impregnated with HCN are opened in the room to be fumigated, and the room is sealed for 24 hrs. The room is then opened for 20 hrs., and the atm is tested for HCN by hanging up paper strips impregnated with 0.25% soln. of $Cu(AcO)_2$ and benidine. If HCN is present, the paper turns blue.

Pigments of butterflies' wings. I. Melanargia galatea. D. L. THOMSON. *Biochem. J.* 20, 73-5(1926).—By successive extrs with ether, ammonia and alcohol, and a final pptn. from an alk. soln. by means of acid, a yellow cryst. powder, sol. in AcOH and hot alc., was obtained. The m p was 253° and the mol wt (by Rast's camphor method) 313, with a probable error of not less than 10%. T thinks the pigment is a flavone or flavonol.

The substance in the oyster and edible mussel giving a positive naphthol reaction. W. LOELE. *Centr. allgem. Path.* 36, 8-12(1925).—The cells contg. this substance are enumerated. They give a gray-violet color when put into an alk. naphthol soln.

F. B. S.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

A modification of the calcium pectate method for the estimation of pectin. A. M. EMMETT AND M. H. CARRÉ. *Biochem. J.* 20, 6-12(1926); cf. *C. A.* 16, 1994.—"The authors criticize the methods in which pectin is pptd. by neutral 95% alc., "owing to the failure of alc. to ppt. a dil. soln." Acidified alc. is much better. Where the pectin solns. contain substances precipitable by Ca, the authors ppt. first with acid alc., and then dissolve the ppt. and reppt. as Ca pectate.

BENJAMIN HARROW

Effect of short periods of cold storage on beef and mutton. W. M. CLIFFORD. *Biochem. J.* 19, 998-1003(1925).—Beef and mutton kept at 25° F. and 35° F. appear identical in appearance with freshly killed meat up to the third day of storage, on the sixth day, kept at 25° F., they show ice spicules and the red color characteristic of frozen meat. In hot English weather, beef and mutton will not keep for 6 days in a room at 35° F. There was no change in total N, sol. N, amino N, carnosine or creatine in meat kept at 35° F. for 3 days, or at 25° F. for 13 days.

BENJAMIN HARROW

Crystals found in canned salmon. E. D. CLARK AND R. W. CLOUGH. *Pacific Fisherman* 23, 11-2(Oct., 1925).—Complaints were made of the presence of broken glass in cans of salmon. The material was found to be not glass but crystals of $MgNH_4PO_4$.

E. H.

Effect of chemical preservation of eggs upon the stability of their vitamin contents. ERNEST TSO. *Biochem. J.* 20, 17-22(1926).—"Pidan" is made from raw duck eggs by applying a mixt. of slaked lime, straw ash, soda, table salt and water. In these preserved (Chinese) eggs, the vitamin B content has been destroyed, without, however, affecting the vitamin A or the antirachitic factor.

BENJAMIN HARROW

Note on the storage of eggs. E. A. GRIFFITHS, D. J. R. DE VILLIERS AND LEITCH ANDERSON. *Dept. Agr., Union S. Africa, Science Bull.* 41, 16 pp(1925).—In eggs with 16 eggs the f. p. of the albumin varied from 30.55 to 31.65° F. and that of the yolk from 30.74° to 31.82°, the av. being 31.29° and 31.38°, resp. In some cases the yolk froze at a lower temp. than the albumin and *vice versa*. F. p. detns. on eggs laid by the same hen on 3 successive days showed no definite trend. Under suitable conditions eggs could be kept in storage for several months at 28° without freezing. White-shelled eggs lost wt. more rapidly in storage than brown eggs. Varnish and wax were not suitable agents for reducing evapn. losses. Eggs coated with the former were contaminated by the solvent and the latter caused bursting in a no. of cases. Coating with oil at 250° F. was effective in preventing evapn. losses but detracted from the appearance of the eggs.

K. D. JACOB

Simplified determination of milk fat in fat mixtures. J. GROSSFELD. *Z. deut. Oel-Fett-Ind.* 46, 49-51, 65-6, 84-5, 97-9, 114-5, 130-2(1925); cf. *C. A.* 19, 3548—G. records an extended investigation of detg. butter fat in mixts. by means of his "butyric acid no.," which expresses the amt. of sol. volatile fatty acids which distills over after the saponified fat has been treated with a satd. soln. of Na_2SO_4 and caprylic acid (coco-nut oil fatty acids) and has been acidified with H_2SO_4 expressed as 0.1 N acid and boiled.

(1) The ratio no. V is suitable for the detn. of milk fat in the presence of coconut oil. (2) V equals 3.8 for the R.-M. no., 12 for the B no. of Bertram, Bos and Verhagen, and 20 for the new distn. no. of van Gilmour. More accurate values are obtained by incorporating other constns. such as the sapon. no., the A no. of Bertram, Bos and Verhagen and the Polenske no. or the sum of the Polenske and R.-M. no. (van Gilmour). (3) Bertram, Bos and Verhagen's method is far superior to older methods but more complicated than van Gilmour's. (4) G.'s expts. increased the V value to 81 by salting out the acids with Na_2SO_4 soln., satd. with caprylic acid; but for coconut oil the value could not be reduced to zero. (5) By incorporating the sapon. no. the milk fat content can be accurately detd. to within $\pm 1.0\%$. (6) A simple method is described for detg. the "butyric acid no.," which on the basis of a 5 g. sample has the value of 20 for milk fat, 0.9 for coconut oil and 0 for other edible fats of low sapon. no., -0.3 to -0.8 for oils and for fish-liver oils, but the latter may be brought to 0 by appropriate modification. (7) The butyric acid no. is practically proportional to the milk fat content. Smaller samples than 5 g. furnish a higher value and larger ones a lower value. Increased temp. when the soap soln. is acidified gives lower results. (8) Under varying exptl. conditions the titration values depend upon the distribution of the sol. acids between the salt soln. and the liquid insol. acids and this influence overshadows the soly. proper of the fatty acids in H_2O . (9) Caprylic and caproic acids are more influenced by this distribution ratio than butyric acid, so that the name "butyric acid no." is justified. (10) A formula is derived for the calcn. of the probable milk fat content M in a fat mixt. from the butyric acid no. b and the value V (sapon. no. less 200), viz.: $M = 5.115b - 0.085V$ and a table has been calcd. for convenience. (11) Com. margarins furnished the butyric acid nos. 0.0 to 0.6 with sapon. nos. of 194-223, equal to 0.0 to 1.1 milk fat by calcn. Com. butter samples yielded a butyric no. of 18.6-23.0, mean 20.3, equal to 3.28-4.05% butyric acid, corresponding to a mean R.-M. no. of 27.3. The factor for calcg. the butyric acid no. from the R.-M. no. is 745. *Method*—Saponify in a R.-M. flask over the free flame 5 g. of the fat with 2 cc. KOH (75% g. in 1000 cc.) and 10 cc. glycerol and dil. the resulting clear soap soln. carefully after a few min. with 100 cc. H_2O . When cooled to 20° add, while shaking, 50 cc. dil. H_2SO_4 (25 cc. coned. H_2SO_4 in 1000 cc.), 15 g. powd. anhyd. Na_2SO_4 , 10 cc. of coconut oil soap soln. (described below) and about 0.1 g. purified kieselguhr. Let stand 10 min. or longer with repeated shaking and filter through a dry folded paper with fine pores. Of the perfectly clear filtrate dil. 125 cc. with 50 cc. H_2O in a 500-cc. round-bottom flask; add some pumice stone and distil 110 cc., titrate directly with 0.1 N caustic and phenolphthalein. Subtract from the no. of cc. used the amt. required for a blank detn. and multiply the result by 1.40, giving the butyric acid no. *Prepn. of the coconut oil soap soln.*—Heat carefully 100 g. coconut oil, 100 g. glycerol and 40 cc. of the above KOH soln. in a l flask with shaking until a clear soap soln. is obtained. Let stand, dil. carefully to 1000 cc. A modification of this method is also given for the detn. of very small amts. of milk fat in which a 15% soln. of MgSO_4 is used to ppt. all acids of high mol. wt., including oleic, linolic and linolenic acids, which exert a disturbing influence on the distribution of butyric acid between H_2O and org. solvents. P. ESCHER

Lactose determination. H. WEISS AND B. BEYER. *Milchwirtschaft Forsch.* 2, 108-12(1925); *Ber. ges. Physiol. exptl. Pharmakol.* 31, 10(1925).—Besides the method of Bruhns that of Weiss is recommended, a detailed description of which is given.

MARY JACOBSEN

Freezing data on ice cream. C. D. DAHLE. *Ice Cream Trade* 22, No. 3, 63(1926). The f. ps. of ice-cream mixes of variable ingredient content were detd. Sugars and water-sol. substances lower the f. p. of ice cream mixes; they also increase the total freezing time. The influence of glucose and corn sugar, in lowering the f. p. against cane sugar, was brought out. General physico-chem. laws seem to hold true for ice cream freezing. H. F. ZOLLER

Investigations in fig culture and treatment. S. R. GANDHI. Dept. Agr., Bombay Presidency, *Bull.* 117, 27 pp.(1924).—Fresh Poona figs contained H_2O 75.0, total sugar 17.2 and reducing sugars 15.2%. The compn. of the dried figs was ash 3.2, ether ext 0.7, proteins 4.7, digestible carbohydrates 89.3 and fiber 2.1%. The water and reducing-sugar contents of Persian, Afghanistan, Grecian and Smyrna figs are given. K. D. JACOB

Size and maturity of canned peas. C. F. MUTTELT. *Ann. fpls.* 10, 74 6(1926). Regenerated mature peas canned to imitate green peas can be distinguished by draining, washing in cold water, drying in vacuum over H_2SO_4 to const. wt., and measuring. Regenerated peas have a considerably greater diam. than even "semi-fine" or "medium"

peas. Screening of the peas, either before or after canning, cannot give reliable indications as to the degree of maturity. Cf. following abstr. A. PAPINEAU-COUTURE.

Procedure for distinguishing "regenerated" preserved dry peas from preserved green peas. C. F. MUTTLERT. *Compt. rend.* 182, 238-40 (1926).—Four samples of canned green peas contained an av. of 58% hydrolyzable matter of which 10% is sol. and 21.8% nitrogenous material of which 4.7% is sol. The corresponding figures for canned regenerated dry peas were 63.5, 5.3, 23.5 and 2.2. The green peas averaged 12.1% cellulose, the ratio of starch to sugars was 5.1, starch to cellulose 4.1, insol N to sol. N 3.8. The corresponding figures for dry peas were 7.8, 11.2, 7.6 and 9.6%. Cf. preceding abstr.

Influence of cooking and of malting on the digestibility of leguminous starches. R. LECOQ. *J. pharm. chim.* [8] 3, 12-5 (1926); cf. C. A. 16, 2151.—The optimum proportion of malt flour acting on raw and cooked flours of lentils and of wheat is 30%, and the optimum temp. is 75° for raw and 60° for cooked flours. The raw starches of lentil flours are less easily converted into reducing sugars by maltase than those of wheat flour, but the action of maltase on the cooked flours yields practically the same (and increased) quantity in both cases. Hence the addn of malt flour to cooked leguminous starches (A) is a convenient means of aiding their digestibility. Moncaux's observation (C. A. 18, 134) that pancreatic juice acting on A produces less maltose than with starches of wheat and other cereals suggests that possibly malt amylase is more active towards A than is the amylase of the pancreatic juice. L. W. RIGGS.

Determination of moisture in wheat and flour. IV. HARRY SNYDER AND BETTY SULLIVAN. *Ind. Eng. Chem.* 18, 272-6 (1926); cf. C. A. 19, 1605.—Fifty-eight flour moisture tests obtained by drying in a current of H₂ yielded 0.54% more moisture than vacuum oven drying at 100° and 600 mm. and upwards. Flour moisture results are relative rather than an abs. expression of moisture content. S. WALDBOFT.

The conditioning and milling of grain. C. H. BRIGGS. *Northwestern Miller* 144, 988, 1307 (1925). RUTH BUCHANAN.

Methods of storing and aging flour. C. H. BRIGGS. *Northwestern Miller* 144, 452 (1925). RUTH BUCHANAN.

Moisture in flour. W. W. SKINNER. *Baking Tech.* 5, 72-7 (1926).—Changing of moisture limit is discussed from the viewpoint of the miller and the public. The change of analytical methods since the establishment of the 13 1/2% moisture standard is considered. If any change in limit is to be made, it should be changed by as much as the differential between the assumed moisture and what the true moisture is finally found to be, or that upon which the standard was based be continued in use. R. B.

The calcium and phosphorus content of commercial wheat flours. C. B. MORISON AND M. R. REESER. *Baking Tech.* 5, 86-7 (1926).—Tables are given showing the Ca and P content of com. brands of wheat flour for the purpose of supplementing older information found in textbooks such as König, Sherman and Leach. A. O. A. C. methods were used for the analytical detns. Data given are of contemporary interest as it is from flour obtained under modern milling conditions. RUTH BUCHANAN.

Studies on the toxicity of copra meal. I. VICTOR SULIT. *Philippine Agr.* 14, 511-22 (1926).—Analyses of the copra meals used are given. Copra meal is toxic to guinea pigs when it constitutes a large part of an otherwise complete ration, but promotes health and vigor when it does not constitute more than 37% of the ration. The symptoms, which developed irrespective of the oil content of the meal used, suggested scurvy, but liberal administration of tomato juice was not beneficial. Twenty-two citations are appended. A. L. MERRINS.

Fluorine cachexia in herbivorous animals fed on forage experimentally altered by treatment with gases containing fluorine. H. CRISTIANI AND R. GAUTIER. *Compt. rend. soc. biol.* 93, 911-2 (1925); cf. C. A. 19, 3521. S. MORGULIS.

Study of the effect of fodder altered by fumes from aluminum factories on animals: fluorine cachexia in cattle. H. CRISTIANI AND R. GAUTIER. *Compt. rend. soc. biol.* 93, 912-4 (1925).—Fodder so treated produces cachexia and finally death. S. M.

Shervi as a fodder crop. ANON. Dept. Agr., Bombay Presidency. *Bull.* 115, 12 pp. (1924).—Shervi (*Sesbania acgyptiaca*) may cause diarrhea when fed to cattle in amts. greater than 10-15 lbs. per day, but in limited quantities it is a valuable supplementary food. A sample of the green fodder contained H₂O 68.25, ether ext. 1.61, proteins 5.50, digestible carbohydrates 11.99, fiber 9.07, ash 2.58, and total N 1.01%. K. D. JACOB.

Philippine citrus fruits (Wells, et al.) HD. Determination of moisture (Tausz, Rumm) 7.

WARTH, A. H.: *Carbonated Beverages*. Baltimore: The Williams & Wilkins Co.
 HUBER, KARL: *Die Obstverwertung*. Berlin: P. Parey. 216 pp. R. M. 6.

Apparatus for pasteurizing milk in bulk. A. J. DAVIS. U. S. 1,578,267, March 30.
Sterilizing and deodorizing milk and cream. F. L. ARMITAGE. Brit. 237,899, Aug. 2, 1924. Mech. features.

Skim-cheese. C. M. GERE. U. S. 1,578,820, March 30. Skim milk is coagulated at a temp. of about 31° and the curd thus formed, after sepn. from the whey, is worked up at about the same temp., then soaked in whey which has been cooled to about 22°, drained to remove surplus whey, warmed to substantially its original temp., pressed and cured.

Ripening cheese. R. W. COON. U. S. 1,579,196, March 30. Cheese with an original moisture content of 36-40% is exposed to a temp. of about 13-21° and a humidity of 75-90%.

Butter. B. PLISIC. U. S. 1,572,123, Feb. 9. Milk is heated to "blood heat" and churned at this temp. until the milk is in a light white creamy form. The butter is then skimmed off, melted and cooled.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Laboratory of the Société Française des Constructions Babcock & Wilcox. C. ROSZAK. *Technique moderne* 18, 137-8(1926).—Brief description of the chem. and of the phys. testing labs. A. PAPINEAU-COUTURE

Studies in filtration. J. W. HINCHLEY, S. G. M. URE and B. W. CLARKE. *J. Soc. Chem. Ind.* 45, 1-10T(1926).—A discussion is given of Poiseuille's law and the formulas of Lewis, Baker, Sperry, Alliot, Donald and Hunneman, and Hatschek. Expts. were run on small lab. filters of both suction and pressure type. The solns. were prepd. by pptg. CaCO_3 , MgCO_3 , $\text{Ba}_3(\text{PO}_4)_2$ and $\text{Al}(\text{OH})_3$ and allowing to stand overnight to form cryst. ppts. Eleven tables and 11 figures are given showing the results. With filtration under vacuum, (a) neither thickness of cake nor compn. of liquor affected the structure of the cake, (b) increase in vacuum gave no evidence of consolidation of cake, (c) compn. of prefil does not apparently affect the structure of the cake. With pressure filtration with CaCO_3 , (a) increase in pressure increases solids in cake, (b) as the solids in the prefil decrease the solids in the cake increase. Different filter cloths offer different resistances. With cakes over $\frac{1}{4}$ inches the flow is directly proportional to the pressure, but for thinner cakes the flow depends upon some power of the pressure. Cakes of different structure are shown to offer different resistance. Curves plotted with resistance against cake thickness are straight lines. L. A. PRIDGEON

Some practical applications of the Lewis filtration equation. H. C. WEBER and R. L. HERSHEY. *Ind. Eng. Chem.* 18, 341-4(1926).—The derivation and integration of the filtration equations given by Walker, Lewis and McAdams in "Principles of Chemical Engineering" are given. An exptl. method of examg. these equations on commercial app. filtering defecated sugar solns. is described and results of a series of expts. are tabulated and discussed. It is valuable in estg. the proper amt. of filter aid. Within the accuracy of plant measurements, the equation is generally valid. L. A. PRIDGEON

Cooling by evaporation. FRIEDRICH MERKEL. *Z. Ver. deut. Ing.* 70, 123-8 (1926).—A development of the theory of heat exchange between the surface of water and air, moving in counter currents, leads to the expression $Wd\vartheta = k(i'' - i)dF$, where W = water going to cooler, ϑ = temp. of water, k = proportionality constant, i'' and i = heat content of moist air at ϑ and t , resp. (temps. of water and air), and dF = area over which transfer occurs. The heat content of in- and out-flowing air, rather than its temp. and moisture content, is the important factor. By integration and graphic development curves are derived, and these are tested by comparison with exptl. results from studies on different types of cooling devices. "The practical conclusion is that the cooling effect is improved more by increasing the quantity of air employed than by subdividing the water more minutely." W. C. FBAUGH

Temperatures of the evaporation of water into air. W. H. CARRIER and D. C. LINDSAY. *Refrigerating Eng.* 11, 241-57(1925).—A thermodynamic treatment of drying and cooling by evapn. Equil. temp. is measured accurately by the wet-bulb thermometer, and this throws much light on the fundamental laws involved in all com.

drying processes. The amts. of error in the wet-bulb temps. have been detd. by the authors and applied in obtaining the theoretical temps. of equilibria. Tables contg., and formulas for arriving at these errors are given. H. F. ZOLLER

Concentration by fractional condensation. J. L. YOUNG. *Ind. Eng. Chem.* 17, 984(1925).—Inserting four fractionating bulbs of special design between a boiling flask and a condenser makes it possible to collect five fractions of the distillate. Students' expts. showed 85–90% EtOH in the last bulb and a concn. of only 2–3% in the first. The result represents the equil. existing at the time the distn. is interrupted. W. C. EBAUGH

The flow of liquids. A. H. McADAMS. *Refrigerating Eng.* 11, 279–306(1925).—When a fluid flows at const. rate through a pipe the motion may be either turbulent or viscous. For isothermal flow the mechanisms of the 2 types of motion are discussed, and data are given to verify the mental pictures of these mechanisms. It is shown that the dimensionless ratio Du/μ has a controlling influence upon the numerical value of the friction factor, the equiv. frictional length of an elbow, the ratio of av. to axial velocity, and upon a 4th dimensionless ratio involving the coeff. of heat transmission between the wall of the pipe and the liquid flowing inside the pipe. In addn. auxiliary data are given as to the effects of temp. and concn. upon both viscosity and sp. gr. and of sp. heat, sp. gr. and av. mol. wt. upon the coeff. of thermal cond. So far as possible such data are given for fluids of interest to refrigerating engineers. H. F. Z.

Roasting and burning ores, limestone and similar materials. ANTON APOLD AND HANS FLEISSNER. *Chem. Ztg.* 50, 156–7(1926).—An experimental plant was made by using a shaft roaster through which siderite (spathe iron ore) descended while hot gases ascended. These gases were obtained by burning powd. coal in the usual way, but mixing cold air (from the one fan) with the products of combustion so as to yield a gas mixt. of about 650°. This entered the roaster through the sides and the central hearth. Cold air blown into the bottom of the shaft roaster mixed with the heated air above, giving a temp. of about 450°; spathe iron roasts quickly at this temp. Fuel economy and other advantages are claimed. Ca and Mg carbonates, etc., can be burned readily in the same plant if suitable operating temps are maintained. W. C. EBAUGH

Movement of materials in industrial plants. VON BRZOLD. *Chem.-Ztg.* 49, 855–6(1925); cf. C. A. 20, 100.—This concludes an elementary presentation of the theory and practice of conveyor systems. W. C. EBAUGH

Methods of packing chemicals for export. ANON. *Chem. Age* (London) 14, 294–7(1926). E. H.

Safeguards against accidents in chemical works. A. O. JONES. *J. Soc. Dyers Colourists* 42, 83–6(1926).—Safeguards against accidents caused by machinery, fire, handling and transportation of materials and poisoning are discussed. I. W. RIGGS

Regulations proposed following the tetraethyl lead investigation. ANON. *Ind. Eng. Chem.* 18, 432–3(1926). To be considered at a meeting of health authorities with Surgeon General in May, 1926. They cover the manuf. of PbEt₄ and blending to make ethyl fluid, ethylizing gasoline, distribution of ethyl gasoline, automobile garages, repair shops, service stations and filling stations. C. M. SALLS

Chronic benzene poisoning. Report of a case with necropsy findings. F. J. ROHNER, C. W. BALDRIDGE AND G. H. HANSMANN. *Arch. Pathol. Lab. Med.* 1, 221–6(1926).—A description is given of a typical case of benzene poisoning, with a history of industrial exposure to fumes of benzene. HARRIET F. HOLMES

Modern trend in applying ozone to cold storage. F. E. HARTMAN. *Refrigerating Eng.* 11, 400–15(1925); cf. C. A. 19, 548. —A review of the field in an able manner. Quant. study of the application is urged. Types of com. app. are discussed. H. F. ZOLLER

The production of low temperatures. BALTZAR VON PLATEN AND C. G. MUNTERS. *Refrigerating Eng.* 12, 142–8(1925).—A small absorption refrigerating machine has been designed from thorough thermodynamic considerations. Elec. heat is employed for driving the dissolved NH₃ gas from the H₂O absorber. Use is made of an inert gas (H), which is lighter than NH₃, to act as a lifting-pump (injector) for circulating the NH₃. H. F. ZOLLER

Determination of the diameter of pore and pore number in filter stones (Ruoss) 2. Stoneware and chemical industry (Binz) 19.

Chemiker-Kalender. Vol. III. Ed. by Walther Roth. Berlin: Julius Springer. 592 pp. R. M. 16.50. Reviewed in *J. Am. Chem. Soc.* **48**, 1115, Vol. I & II. Cf. C. A. 19, 1654.

Comminuting solids and forming colloidal solutions. O. AUSPITZER. U. S. 1,577,052, March 16. Mech. features.

Separating gases. E. B. MILLER. U. S. 1,577,534, March 23. Silica gel or similar finely divided porous solid gas-adsorbing material is fed into a stream of mixed gases such as air carrying vapors of volatile liquids and the adsorbed gas is subsequently sepd. and the adsorbent used again, in a cyclic process. An app. is described.

Electric resistance material. W. OTTO. U. S. 1,577,981, March 23. Finely divided graphite is mixed in different proportions with rubber (which is at least partially vulcanized) to form resistance elements adapted for use as resistance standards, etc.

Electrical insulating material. C. L. DAWES and W. A. BOUGHTON. U. S. 1,578,812, March 30. A mixt. of mica fragments and a binding material, such as NaPO_3 , which at ordinary atm. pressure requires a temp. substantially as high as the disintegration point of mica to render it fluid, is subjected to hot molding under pressure at a temp. below that which would cause the mica to disintegrate. U. S. 1,578,813 specifies the use together of mica fragments and Na silicate.

Electrical insulating composition. F. KRUPP AKT.-GES. Brit. 237,885, July 30, 1924. "Roasted chalk" or other ground insulating material is mixed with mineral oil, for filling hollow spaces in castings contg. elec. conductors.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Modern British practice in water softening. VI. Zeolite or base-exchange plants.

DAVID BROWNLIE. *Ind. Chemist* **2**, 108-12(1926); cf. C. A. 20, 1479.- The following types of zeolite or base-exchange plants are described with illustrations of each (a) Boby-Azed, (b) Kennicott and (c) Permutit. "Doucil," used in type (a), differs from all other base-exchange materials in being a colloid; it is a hard, rigid and homogeneous dried gel with the approx. composition $\text{Na}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot 5\text{SiO}_2$. Of the 13.3% Na_2O about 10% is active. Doucil is sold on a 50% moisture basis, and 1 ton (2240 lbs.) will soften about 25,000 gals. of water of 20° hardness. "Kenzelite," used in type (b), is a natural mineral zeolite. "Permutit B," used in type (c), is made from glauconite. Certain advantages are claimed for the base exchange products prepd. from natural zeolites.

E. G. R. ARDAGH

Purification studies on aerofilters in 1925. N. A. BASIAKINA. *Fifth Report of the Moscow Commission on the Purification of Sewage* **1**, No 3, 127-36(1925). The sewage of Moscow contains chlorides 109.6 p. p. m.; NH_4N 69 p. p. m.; nitrate N 65 p. p. m. and dissolved O 0.0 p. p. m. The demand of air for normal purification is 4 to 6 vols. air to one vol. sewage. Aerofilters are found the most efficient type of disposal plant for the city of Moscow. The proposed plant has a capacity of 12,300 cu. m. of sewage daily.

BEN H. PETERSON

Essentials of correct boiler water conditioning. R. E. HALL. *Power Plant Eng.* **30**, 327(1926); *Proc. Eng. Soc. Western Penn.* **41**, 347-89(1925).- To prevent scale formation, the relation $[\text{CO}_3] = K_1$ (at operating pressure p) $\times [\text{SO}_4]$, which exists when soda ash is used to treat the water, must be maintained with a slight excess of $[\text{CO}_3]$. Allowance must be made for the decompn. of Na_2CO_3 to NaOH , the rate depending upon the pressure and boiler rating. This difficulty may be prevented by the use of the more stable phosphate compds. The relation in this case is expressed by $[\text{PO}_4] = K_2$ (at operating pressure p) $\times (3[\text{SO}_4]/2) \times (D[\text{SO}_4]/2)$, where D is the relation of the ionic to total $[\text{SO}_4]$. Small concn. of NaOH and loose crystals of suspended CaCO_3 prevent scale in water lines and preheating surfaces. Corrosion must be controlled electrolytically. HO ions prevent corrosion in sulfate waters and help in chloride waters.

K. C. BRISON

Stream pollution by acid mine drainage. R. D. LEITCH. *Chem. Age* (London) 14, 266-7 (1926).—See C. A. 20, 959.

Utilization of the gas from Imhoff tanks in city mains. B. NERRETER. *Gas u. Wasserfach* 69, 185-9 (1926).—The gas from 2 activated-sludge (Imhoff) sewage-disposal plants at Essen is mixed with the city coal gas supply. The av. compn of the gas is 80% CH₄, 17.4% CO₂, 0.2% O₂, 2.4% N₂, heating value 7653 kg. cal./cu. m., the limit variation of the compn. being shown by that of the heating value, viz., 7200-8200 kg. cal./cu. m. Charts and tables are given showing production and heating value by monthly averages for 2.5 years, as well as max. and min. daily figures. The total production (1925) of 1 plant was 62,000 cu. m., of the other 341,000 cu. m. W. B. P.

The rate of solution of oxygen as an agent in biological purification. N. BASIAKINA. *Fifth Report of Research on the Purification of Sewage at Moscow I*, No. 3, 139-59. —The rate of solution of O₂ is proportional to the difference between the O₂ concn in a satd. solution and the concentration in a given solution and is given by the equation $dx/dt = k(b-x)$, in which b is the value in a satd. solution and x is the concentration in the given solution. The value of $b-x$ depends upon the rate at which the sludge uses up the dissolved oxygen. Experimental determinations of the rate of oxidation of ammonia nitrogen show it to be proportional to the rate of solution of O₂. The dissolved O₂ content of the effluent of the Moscow plant is about 4.65, about half saturated. BEN H. PETERSON

Water filter. R. H. SMILIE. U. S. 1,579,158, March 30

Base-exchanging silicates for purifying water. NORDISCHE NATROLITH AKTIESELSKAB. Brit. 237,626, July 25, 1924. A substance suitable for removing Fe, Mn, Ca and Mg from H₂O is prep'd by granulating clay, calcining it at 500-700° and then treating it with a soln. of alkali hydroxide or carbonate, e. g., boiling it for 1/4, 4 hrs with a soln. corresponding to 1% Na₂O or a 2% Na₂CO₃ soln.

Separating scale-forming ingredients from boiler feed-water by preheating and sedimentation. O. GÜNTHER. U. S. 1,579,414, April 6. Mech. features

"Boiler compound." W. P. PECK. U. S. 1,579,949, April 6. A boiler cleaning mixt. is formed from ext. of hemlock 40 lbs., Na₂CO₃ 60 lbs., brown sugar 10 lbs. and H₂O 30 gals.

Sewage and water clarifying tank. H. L. THACKWELL. U. S. 1,578,691, March 30.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Broadening agricultural chemistry. WM. P. HEADDEN. *J. Chem. Education* 3, 201-12 (1926).—Problems arising in connection with the raising of sugar beets and wheat in Colorado are good examples of how general principles of agriculture, based largely upon results under humid conditions, need material modification when applied to other conditions. The tacit assumption that irrigation and rainfall produce the same effects upon the wheat crops is wholly wrong. P. R. DAWSON

The sourness of soils. N. M. COMBER. *Rept. British Assoc. Adv. Sci.* 1923, 495. *Botan. Abstracts* 14, 768. Sourness in soils is recognized from the agricultural point of view by the failure of certain plants and the dominance of others, the prevalence of certain diseases and a rectification of these conditions following the use of lime. C. holds that the cause of sourness is not the H-ion concn. nor the ratio of Ca to other metals. There is, however, evidence that the ratio of basic lime to weak bases, chiefly alumina, is the fundamental cause of sourness. The function of lime appears to act as a flocculent of the soil colloids and the root-hair colloids and to prevent too great an uptake of alumina and other toxic substances. H. G.

The quinhydrone method and the relationship of its results to the forms of acidity of the soil. H. KAPPEN AND R. W. BELING. *Z. Pflanzenernähr. Düngung* 6A, 1-26 (1926).—The quinhydrone method was found to be a rapid and useful method for the detn. of the H-ion concn. of soil suspensions. The small amts. of electrolytes in soils were found to lower the H-ion concns. of soil suspensions; washing increased the pH value of soil suspensions. The authors call the relationship (called the acidity quotient) of the "hydrolytic acidity" to the "exchange acidity"—and maintain that in soils where the quotient exceeds 6 that part of the base cated by the Daikuhara formula is used for the neutralization of the "hydrolytic acidity" and that the "exchange acidity" is therefore not neutralized. Filtrates of soils (both in water and in KCl soln.) were

found to be less acid than the corresponding suspensions. This result is explained on the basis that active H-ions are held by the finer soil particles. In using the quinhydrone method it was found that care must be taken to have sufficient quinhydrone, especially for large amts. of soil. 500 mg. was sufficient for suspensions. contg. 100 g. of soil. The electrometric titration of soil suspensions was carried out successfully by the quinhydrone method. It is maintained that another argument for pure Al-exchange with acid soils and neutral salt solns. is in the fact that a const. p_H value is obtained immediately upon the addn. of a neutral salt soln., which would not be the case if HCl (by exchange of cation with H-ion) were first formed and Al subsequently dissolved.

R. M. BARNETTE

The question of the exchange acidity of soils and the connection between "titration" and "actual" acidity. H. NIKLAS AND A. HOCK. *Z. Pflanzenernahr. Düngung* 5A, 370-92(1925).—Supporting the views of Kappen on the nature of soil acidity, the authors find a relationship between the p_H and the total (titration) acidity of KCl exts. of mineral soils. By means of this relationship, based on the hydrolysis curve of $AlCl_3$, the authors maintain that either the p_H or the total acidity may be used to det. the reaction of an acid soil. This relationship was not found to hold for humus contg. soils, for forest soils, nor for soils with p_H values above 4.6 (in the KCl ext.). Only in soils with so-called "exchange acidity" is the correlation perfect. Iron was found to play a part only in extreme cases, i. e., subsoils of forest soils. The difference between the theoretical (from titration) and the detd. amts. of Al_2O_3 (in pure Al salt solns. and in KCl exts. of soils) was shown to be dependent upon the concn. of the Al salt.

R. M. BARNETTE

The origin of alkali land. ALBERT HOWARD. *Agr. J. India* 20, 461-2(1925). H. suggests that the gradual alteration of fertile soils into dead alkali land has much in common with the observations of Ossendowski (Man and Mystery in Asia, London p. 5, 1924) on vast colonies of reducing bacteria, *Beggiatoa bacilli*, in lake Szira kul, Siberia, and the intermediate stages that occur between ordinary fresh water lakes and reservoirs of dead salt water.

RUSSELL M. JONES

Method for the determination of the fertilizer requirements of soils. ALFRED MITSCHERLICH. *Z. Pflanzenernahr. Düngung* 4B, 193-9(1925).—An extension of the polemic between M. and Gerlach over the calcn. of consts. in the M formula for the calcn. of yield increases resulting from definite fertilizer applications; and of that between M. and Lemmermann over the adaptability of field and pot expts. for such calcns.

R. M. B.

The Mitscherlich procedure for the determination of the fertilizer requirements of soil. GERLACH. *Z. Pflanzenernahr. Düngung* 4B, 273-85(1925). Polemic

R. M. BARNETTE

An explanation for the relative effects of timothy and clover residues in the soil on nitrate depression. B. D. WILSON AND J. K. WILSON. *Cornell Univ. Agr. Expt. Sta. Memoir* 95, 1-21(1925).—Clover roots and hay were completely oxidized in the soil in less time than those of timothy were; this is due to the greater N content of the former. The evolution of CO_2 was directly proportional to the bacteria counts from the soil contg. decomposing clover and timothy. The soil organisms are believed to remove sol. nitrates from the soil soln. to be returned again later when their bodies decompose. Eleven references are appended.

A. I. MEHRING

Productivity of the soil as a function of its physical structure and changes in soil structure and composition during vegetation. W. NITZSCH. *Wiss. Veröff. Siemens Konzern* 4, Heft 2, 75-94(1925).

C. G. F.

Humification of the dead covering of forest soils. ANTONIN NEMEC. *Compt. rend.* 182, 590-2(1926).—Eight samples of the floor covering from pine forests of 30 to 100 years old showed that the percentage of org. matter varied with the age of the covering and that the p_H of the soil soln. was generally more acid with age although this figure was modified by the presence or absence of moss and herbage. The loss or gain of nitric N, by the H_2O_2 method of Robinson, bore a rough direct relation to the p_H value, but was more affected by the kind of trees in the forest. L. W. RUGGS

Studies on the growth of some Danish agricultural plants in soils with different concentrations of hydrogen ions. CARSTEN OLSEN. *Compt. rend. trav. Lab. Carlsberg* 16, No. 2, 21 pp. (1925).—Portions of a highly acid soil (p_H 4.0) were brought to a p_H range of 4.0 to 7.5 by thorough mixing with $CaCO_3$. Where a higher alk. was required, $Ca(OH)_2$ soln. was necessary. The plants were grown in pots of the soil thus prepd. and with the addn. of heavy applications of appropriate nutrients. The p_H was detd. before and after the expt. and the mean taken. Alfalfa showed a very

regular growth curve with a summit at approx. pH 6.5-7.1; *Medicago lupulina* showed a similar curve with a summit at approx. pH 6.5-7.0; barley produced its best growth at pH 6.5-8.0; rye attained a summit at approx. pH 6.2; and buckwheat reached its max. at about pH 6.0-7.0. In the case of alfalfa growth fell off most markedly on the side of decreasing pH ; the same was true of *lupulina*; with barley the drop on the acid side was less marked; rye appeared less sensitive to such variations than the preceding plants; while buckwheat showed a rapid drop with increasing pH , but a more gradual drop on the acid side. Rye and buckwheat are far more tolerant of high H ion concn. than the other 3 species; less difference was shown in the tolerance of high pH . No evidence was deduced of double summits of growth curves as reported by Arrhenius. The results are considered chem. valid in the presence of the high concns. of nutrients employed. Since the growth curves showed a drop at a pH higher than that of the summits, it is evident that in the culture of even such edemiphilous plants as alfalfa too much lime can be applied.

P. R. DAWSON

Physiological importance of extractable nutrients, a contribution to the determination of the fertilizer requirements of soils by chemical means. BLANK AND F. ALTEN. *J. Landw.* 73, 219-30 (1925).—The amt. of P_2O_5 extd. from a soil by a variety of acid solvents was detd., the weaker acids being used both with and without making allowance for the carbonates present in the soil. Oats were then grown on sand culture receiving P_2O_5 equiv. to the varying amts. extd. by the different solvents, each pot having the same application of other essential nutrients. It is concluded that only dil. acids are suitable solvents for detn. of assimilable P_2O_5 in soil. Of those tried 1% nitric, 1% acetic acid and 0.5% citric acid gave satisfactory results, if the amt. used was adjusted to allow for neutralization by the carbonates present. Water saturated with CO_2 was, however, quite unsuitable.

F. M. SCHERTZ

The isoelectric theory. Its application to certain problems of crop products manufacture and soil fertility. I. F. HARDY. *Trop. Agr. Trinidad* 2, 179-81 (1925).—A discussion of the isoelec. point of proteins. The ease of pptn. of hydrophilic colloids by certain ions bears a definite relation to the dehydrating power of the latter, and this fact is suggested as throwing considerable light upon the mechanism of simple salts. II. *Ibid* 208-9.—A description of the physical chemistry of the coagulation of rubber latex. The view is held that coagulation phenomena in rubber latex are manifestations of the reactivity of lightly hydrated protein films that effectively protect globules of caoutchouc dispersed in an aq. serum. III. *Ibid* 251-3.—A no. of obscure points in connection with the delecation of sugar cane juice are discussed in connection with this theory. IV. *Ibid* 256-8.—The isoelec. point of cacao bean protein was found to be pH 3.8. The fermentation and acid processes of preparing cacao beans are discussed in the light of the isoelec. theory. V. *Ibid* 283-5.—Laterite soils predominate in the tropics and their chief component is hydrous alumina, the isoelec. point of which is pH 6.5. Applications of superphosphate flocculate this type of soil in exactly the same manner that lime flocculates a hydrous silica soil. Two to seven references are given with each part.

A. L. MEHRING

The rate of absorption of nitrate of soda by oats and cotton when applied at different stages of plant growth. W. H. APPLETON AND H. B. HELMS. *J. Am. Soc. Agron.* 17, 596-605 (1925).—In greenhouse expts. $NaNO_3$ applied at the rate of 400 lbs. per acre 14 days after planting, absorption of the nitrate was very slow for 3 weeks. After the 3rd week absorption increased and all nitrate was absorbed by the close of the 7th week. When nitrate was applied to oats at later stages of growth, the rate of absorption was more rapid. Nitrate applied 42, 70 and 92 days after planting was completely absorbed in 20, 14 and 10 days, resp. With both oats and cotton there was a close correlation between rate of growth and rate of nitrate absorption. $NaNO_3$ at the rate of 600 lbs. per acre was applied to cotton, 14, 40 and 64 days after planting. Absorption of the nitrate was completed in 30, 14 and 11 days, resp.

F. M. SCHERTZ

Investigation of the development and composition of potato plants under the influence of different fertilizers. WERNER HENDORFF. *J. Landw.* 73, 177-212 (1925).—The subjects discussed are: The influence of the vegetation period upon the formation of the potato plant, the dry wt. and the compn. of the ash of the potato plants, the influence of fertilizers upon the formation of potato plants. Microscopical investigation of the stems and the tubers. Influence of fertilizers upon the dry wt. and the compn. of the ash of potato plants.

F. M. SCHERTZ

Carbon dioxide fertilizer. GERLACH AND SCHIEL. *Z. Pflanzenernähr. Düngung* 4B, 241-7 (1925).—A so-called CO_2 fertilizer (composed of peat, charcoal, etc., with small percentages of N, K_2O and P_2O_5) proved ineffective in increasing the yield of lupine in a field expt. on a light sandy loam soil. A pot expt. with lupine on the same

soil substantiated the field observations. In the same expt. MnO_2 increased the yield and crude protein content slightly.

R. M. BARNETTE

Permanent grassland. F. E. CORRIE. *Fertiliser, Feeding-Stuffs and Farm Supplies J.* 11, 127, 131(1926).—Phosphatic fertilizers increase the N content of pastures by promoting growth and development of clovers and other legumes. The N content of a pasture soil receiving phosphates alone over a period of 11 years was increased by 0.05% while another plot receiving $(NH_4)_2SO_4$ and $NaNO_3$ in addn. to phosphates contained 0.04% less than the control. Grass from a pasture plot fertilized with basic slag and lime contained an av. of 1.5 times as much CaO over a period of 6 months as grass from the control plot. The value of mineral compds. in animal nutrition is also discussed.

K. D. JACOB

The agricultural value of dicyanodiamide. C. B. GREENING. *Fertiliser, Feeding-Stuffs and Farm Supplies J.* 11, 162-3(1926).—G. cites the work of a no. of investigators to show that dicyanodiamide and dicyanodiamidine are as valuable as other forms of available N when used in amts. corresponding to not more than 10% of the total N applied under usual farming conditions.

K. D. JACOB

Effects of lime and potash fertilizers on certain muck soils. FERDINAND LOEWING. *Bot. Gaz.* 80, 390-409(1925).—Crops on acid muck soils chemically deficient in lime or potash may be injured by these elements in fertilizers. Use of $CaCO_3$ as fertilizer depressed the K content and the K/Ca ratio in crops grown on acid mucks. High yields of clover showed a low K/Ca ratio in tissues. Injuries following lime and potash applications to the soil are marked internally by depression of org. N and carbohydrate content. Antagonism of ions between Ca and K was not observed. High nitrate N is associated with high Ca content of tissues and low crop yield; high crop yield is associated with high organic N and high total carbohydrate content.

B. H.

Comparison of the action on plants of sodium and potassium chlorides and of rich sylvinite. P. LESAGE. *Ann. agron. sci.* 42, 172-91; *Chimie et industrie* 15, 281(1926). Results of tests carried out at the Botanical Gardens at Rennes lead to the following conclusions: (1) Distd. H_2O condensed in a metal worm exerts a toxic action on plants. The toxicity is not always destroyed by dissolved salts in the water, its destruction depending on the nature and concn. of the salts dissolved. (2) $NaCl$ and KCl at equal mol. concns. exert practically the same effects on plant growth, both at high (harmful) concns. and at low concns. In all cases sylvinite gave better results than pure KCl . (3) It does not seem necessary (except possibly for economic reasons) to sep. KCl from sylvinite on the ground that the latter is of value only on account of its KCl content. (4) It is suggested that the Na ions of rich sylvinite can penetrate to the seeds and act in a manner similar to other metals such as Ca and K, giving addn. or substitution products of interest in the utilization of the plants or derived vegetable products.

A. PAPINEAU-COUTURE

The influence of fertilizers in protecting corn against freezing. O. C. MAGISTAD AND E. TRUOG. *J. Am. Soc. Agron.* 17, 517-26(1925).—Application of fertilizers in the hill increases the osmotic pressure of the sap of young corn plants, which in turn lowers the freezing temp. of the plant 1-2° C. Plants grown on soils of low soil salt content such as peats, mucks and poor sands will undoubtedly benefit most from such a use of fertilizers.

F. M. SCHERTZ

The Italian fertilizer "Clumina." P. EHRENBURG. *Z. Pflanzenernähr. Düngung* 4B, 213-5(1925).—"Clumina" is an earth satd. with Cl gas in an attempt to make use of the Cl gas used for the prepn. of war gases. "Clumina" is supposed to make available the org. N of the soil by its sterilizing action followed by a stimulation of the microbiological processes. Pot expts. were not conclusive.

R. M. BARNETTE

The better use of P_2O_5 found in soils. J. WITYN. *Z. Pflanzenernähr. Düngung* 6A, 27-51(1926).—In neutral and slightly alk. soils the P_2O_5 is present chiefly as $Ca_3(PO_4)_2$; in acid soils in combination with org. materials and with Fe and Al hydroxides. With the change in reaction of the soil there is a transition in these compds. W. concludes that $CaCO_3$ or anything increasing the OH-ion concn. will decrease the soly. of $Ca_3(PO_4)_2$, while carbonic acid or anything increasing the H-ion concn. will increase the soly. He concludes that carbonic acid and other weak acids decrease the soly. of $FePO_4$ and $AlPO_4$, while alk. materials increase the soly. of these phosphates. For acid soils, liming therefore increases the soly. of the phosphates by changing them into the Ca phosphates. Acid soils usually contain larger amts. of P_2O_5 than neutral or productive soils, only the P_2O_5 is less available.

R. M. BARNETTE

Test with phosphate flour on different soils. K. KALININA. *Trans. Inst. Fertilizers (Russian)* 1925, No. 30, 119-27.—Expts. on some of the black soils of Russia with raw phosphate flour show that they may be utilized by most crops.

J. S. JOFFE

Preliminary report on artificial or synthetic farmyard manure. H. G. MUNDY. *Rhodesia Agr. J.* 22, 447-53 (1925).—The comps. of artificial manures made by the Rothamsted method from corn stalks, green grass and dried grass were, H_2O 72.40, 72.92 and 81.10, org. matter 16.25, 15.48 and 2.37, ash 11.35, 11.60 and 6.52, N 0.55, 0.54 and 0.42, P_2O_5 0.36, 0.46 and 0.34 and K_2O 0.28, 0.29 and 0.21%, resp. A. L. M.

Four years of fertilizer experiments with increasing applications of potash. KUHN ERT. *Z. Pflanzenernahr. Dungung* 4B, 307-9 (1925).— K_2O fertilizers were found valuable for increasing the yield of potatoes and rye on unreclaimed sandy heath soils near Hamburg.

R. M. BARNETTE

The effect of simple and increasing applications of nitrogen, potash and phosphate on different crops. O. NOLTE AND R. LEONHARDS. *Z. Pflanzenernahr. Dungung* 4B, 286-306 (1925).—A review of numerous fertilizer expts. conducted in Germany and in Denmark. By comparing the increase of crop yield for a unit of the fertilizing element (1 kg. of N, K_2O and P_2O_5) the authors find a variation in the effect, particularly of the N-contg. fertilizers, for the various parts of Germany and Denmark. They explain the variation of the effects of the N-contg. fertilizers by the difference in the climate, length of day, etc. A review of the comparative results on various crops fertilized with $NaNO_3$, $(NH_4)SO_4$ and $Ca(NO_3)_2$ showed that $NaNO_3$ and $(NH_4)SO_4$ were alike in increasing the crop yield, while $Ca(NO_3)_2$ was often not as effective as the other two forms of N. From the results with increasing applications of N fertilizers, it was concluded that an application of over 60 kg. of N per ha. would not be profitable. The paper offers an excellent collection of the data obtained in the numerous German and Danish fertilizer expts.

R. M. BARNETTE

Land crabs as agricultural pests in western India. P. V. WAGLE. Dept. Agr., Bombay Presidency, *Bull.* 118, 47 pp. (1924).—A large no. of compts. were experimented with as poisons for land crabs. The best results were obtained by fumigating the burrows with CS_2 .

K. D. JACOB

Derris and its uses as an insecticide. A. S. CARLOS. *Fertilizer, Feeding Stuffs and Farm Supplies J.* 11, 161 (1926).—The milky colloidal soln. of resins and other compts. obtained by extg. the roots and stems of *D. elliptica* and *D. uliginosa* with water has an exceedingly toxic action on insects. As dil. a soln. as 0.025% is effective as a contact poison for aphids while an 0.8% soln. constitutes an effective stomach poison. *Derris* does not injure blossoms and foliage and is not particularly poisonous to warm-blooded animals although quite toxic to cold blooded animals. Leaves sprayed with *derris* soln. remain toxic to insects for many days. The poison has been found effective against caterpillars, aphids, psylla and red spiders. The powd. material may be applied as a dust with equal effect.

K. D. JACOB

The use of petroleum oils as insecticides. E. R. DE ONG. *Oil & Gas J.* 24, No. 36, 142 (1926).—A quick-breaking oil-water emulsion is most effective from the insecticidal standpoint. Citrus sprays should contain two gal. of oil per 100 gals. of mixt. Criteria as to the value of an oil for spraying are sp. gr. and the sulfonation test which is described. Oils having a high sulfonation value are least toxic to plants.

M. B. HART

Colloid chemistry of humus and peat (OSTWALD, STEINER) 2.

CHAMBERLAIN, JOSEPH AND BROWNE, C. A. *Chemistry in Agriculture.* New York The Chemical Foundation. 440 pp. \$1.00

LUNDEGÅRDH, HENRICK: *Klima und Boden in ihrer Wirkung auf des Pflanzenleben.* Jena: G. Fischer. 419 pp. R. M. 24.

Calcium nitrate fertilizer. W. WILD and K. EYER. U. S. 1,579,989, April 6. A hot concd. soln. contg. $Ca(NO_3)_2$ and urea is sprayed into a stream of air or other suitable gas in order to form globular granules.

Phosphatic fertilizers. RHEINANIA VEREIN CHEMISCHER FABRIKEN AKT.-GES. Brit. 237,875, Aug. 1, 1924. A mixt. of a natural Ca phosphate with $MgCl_2$ or $MgSO_4$ (with or without an alkali salt) and enough SiO_2 to form Ca orthosilicate with Ca displaced by the Mg and alkali metal is heated to 900-1100° in an atm. contg. H_2O vapor. Cf. C. A. 20, 964.

Available phosphate from phosphate rock. H. H. MEYERS. U. S. 1,578,339, March 30. Ground phosphate rock is sintered with $NaHSO_4$ or Na_2SO_4 , the sintered mass is crushed into porous lumps and the latter are calcined.

Insecticides. S. LOMANITZ. U. S. 1,577,916, March 23. A "sticker mixt."

for use with insecticides and fungicides is formed of a homogeneous fused mass of soap and S.

Insecticide. G. E. SANDERS and R. H. PESTELL. U. S. 1,577,369, March 16. A mixt. adapted for use on plants comprises nicotine, ammonia, MgO, lime, nicotine, sulfate and $(\text{NH}_4)_2\text{SO}_4$.

Insecticide and fungicide. E. C. HOLTON. U. S. 1,578,520, March 30. A dry powdered mixt. comprises BaF_2 with a smaller quantity of S. U. S. 1,578,521 specifies forming a ppt. for the same purpose by treating an alk. earth polysulfide with SO_2 and H_3AsO_4 or an oxy acid of Se. U. S. 1,578,522 specifies reacting on a polysulfide of Ca with H_2SiF_6 . U. S. 1,578,523 specifies similar use of Ba polysulfide instead of Ca polysulfide.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

The significance of phosphoric acid in alcoholic fermentation. W. WINDISCH. *Wochschr. Brauw.* 42, 297-8(1925); cf. C. Neuberg and A. Gottschalk, *C. A.* 20, 923.-Acetone dry yeast ferments pyruvic acid but not sugar. This is due to deficiency of coenzyme. The dry yeast is unable to form hexose phosphates until coenzyme is added. The cozymase and the apozymase together constitute the true active zymase.

C. N. FREY

Fuel alcohol from brushwood and from waste cellulosic matter. EDMUND MARCOTTE. *Rev. sci.* 64, 110 5(1926).—A discussion of the Memier process (*C. A.* 16, 1664), which consists essentially in saccharifying wood with dil. acid by passing superheated steam through the reaction mixt. and continuously drawing off the volatile decompn. products as soon as formed to prevent their further decompn. The yield and nature of the products obtained can be controlled within fairly wide limits by variation of the operating conditions.

A. PAPINEAU-COUTURE

Alcohol shrinkage in brandies. H. LÜHRIG. *Pharm. Zentralhalle* 67, 49-55 (1926).—A discussion of the factors involved in the apparent shrinkage in alc. content during storage of brandies, notably in wood and glass containers.

W. O. E.

Algerian grape musts of the 1925 vintage. POUGET and BONNIER. *Ann. fals.* 19, 88-99(1926).—Nature of the soil, drainage, vine, climatic conditions during growth and at vintage time, condition of the grapes, yield and analysis of the must are tabulated for 90 samples and briefly commented.

A. PAPINEAU-COUTURE

A wine 100 years old. GIOVANNI ISSOGLIO. *Giorn. farm. chim.* 75, 31-5(1926). The tartaric acid was relatively low. A large part of the malic was converted into lactic acid. Succinic acid, glycerol and alc. were high. p_H was 3.4, ash 0.276%, volatile esters were calcd. as EtOAc 0.027%, total esters calcd. as Et tartrate 0.068.

MARY JACOBSEN

Salicylic acid as a preservative for wine samples. FONZES-DIACON and LAFORET. *Ann. fals.* 19, 99-102(1926).—Samples of wines preserved by addn. of 0.5 g. of salicylic acid showed practically no change in compn. after 1 yr., whether kept in completely filled and well-stoppered bottles, or in partly filled bottles.

A. PAPINEAU-COUTURE

Some methods of detecting irregularities in the composition of South African wines. F. FEVKIER. Dept. Agr. Union S. Africa, Division of Chemistry Series, *Bull.* 34, 17 pp.(1924).—The methods used for detecting adulteration and fortification are discussed in detail and data are given for typical South African wines.

W. O. EMERY

A new preparation for hindering the coagulation of blood. HUGO SCHLESINGER and WILHELM REICH. *Chem.-Ztg.* 49, 961(1925).—"Novirudin," a new compd. belongs to the melanin acid group. It is a dark brown powder, commercially available in 1 and 5 g. packages. 0.5 mg. added to 1 cc. of blood *in vitro* prevents coagulation.

It imparts a dark color to blood, but does not change it otherwise. Injected intravenously 1 mg. per cc. of blood prevented coagulation for 3 hrs. No action was detected on heart, blood pressure or respiration.

The extraction of alkaloids. P. DUROCHER. *La nature* 54, i, 37-40 (1926).—An illustrated description of present large scale production. GEO. R. BANCROFT

The preparation of chloral. P. DUROCHER. *La nature* 54, i, 81-3 (1926).—An illustrated description of large scale production. C. C. DAVIS

Constitution of cyanomercurisalicylic acids and hydrargyrum salicylicum D. A. B. E. RUPP AND H. GERSCH. *Arch. Pharm.* 264, 88-92 (1926).—A series of expts. is described showing that nitration of easily sol. K cyanomercurisalicylate yields *o*-nitrosalicylic acid, while the difficultly sol. K cyanomercurisalicylate gives *p*-nitrosalicylic acid under the same treatment. By utilizing this behavior it becomes possible to differentiate between samples of hydrargyrum salicylicum D. A. B., whether *a* or *p*-mercurisalicylic acid is present, or a mixt. of the two, as follows. Dissolve 2 g. of the sample in 20 cc. H₂O and 30 to 40 drops of official NaOH soln., add 25 g. HNO₃ (1:1) with agitation and heat 1/4 hr. on the steam bath. Cool, filter by suction, boil, filter and ppt. with 100 cc. of H₂O, filter and cool. Collect the crystals, dry at 100-10°, evap. meanwhile the mother liquor one-half and again allow to crystallize. If the crystals remain colorless when dry, the product is solely *p*-nitrosalicylic acid, if they develop color, the product is *o*-salicylic acid, m. 144, or a mixt. with indeterminate m. p.

W. O. E.

Evaluation of digitalis. R. WASICKY, F. LASCH AND K. SCHONOVSKI. *Arch. Pharm.* 264, 92 (1926).—The colorimetric method for the evaluation of digitalis preps. via Knudson-Dresbach is in its present form to be rejected. Methods involving the entire frog or the cat are serviceable as at present in vogue. For practical purposes, the simplest possible method involving use of the frog is preferable, notably the 2 hr. method of Pick-Wasicky.

W. O. E.

Salts of anhydromethylenecitric acid. I. VANINO AND O. GUYOT. *Arch. Pharm.* 264, 113-7 (1926).—With concd. aq. solus. of "citarin" AgNO₃ yielded a white ppt., CuSO₄ green, sol. in excess of citarin, stable on boiling alone, but pptg. Cu with caustic alkali; BeCl₂ immediate white ppt. soon changing to a transparent viscous mass, MgSO₄ cryst. ppt. after a short time; CaCl₂ fine cryst. ppt. on standing, SrCl₂ gradual amorphous ppt.; BaCl₂ immediate heavy amorphous ppt.; ZnSO₄ gradual heavy cryst. ppt.; CdSO₄ very gradual cryst. ppt.; HgNO₃ and Hg(NO₃)₂ white ppt. sol. in large excess of citarin, very slow reduction on boiling the mercurous salt, none with the mercuric salt; AlCl₃ strong white ppt.; Pb(NO₃)₂ white amorphous ppt.; KCr(SO₄)₂ immediate cryst. ppt.; UO₂(OAc)₂ no ppt.; MnSO₄ cryst. ppt.; FeCl₃ red brown ppt. sol. in excess of citarin, soln. giving with NH₃ no ppt. but a red brown color, (NH₄)₂Fe(SO₄)₂ gradual yellowish white amorphous ppt. permanent in the air, Bi(NO₃)₃ immediate white amorphous ppt.; SnCl₂ white amorphous ppt. The following salts were isolated and characterized: lithium anhydromethylenecitrate C₃H₄O₄Li₂·3H₂O, prismatic plates, Mg salt, C₃H₄O₄Mg·2H₂O, Cu salt, C₃H₄O₄Cu·2H₂O, Mn salt, C₃H₄O₄Mn·3H₂O, long prisms; Cr salt, (C₃H₄O₄)₂Cr₂·2H₂O, blue-green needles, Co salt, C₃H₄O₄Co·3H₂O, red crystals; Ni salt, C₃H₄O₄Ni·3H₂O, cryst.

W. O. E.

Siamese benzoin. V. FRIEDRICH REINITZER. *Arch. Pharm.* 264, 131-40 (1926); cf. C. A. 9, 121; 15, 2851; 19, 2724.—The present paper embodies a study of the entire resin. A summary of the author's investigations on Siamese benzoin is presented as follows: (1) Siamese benzoin is originally a purely white, cryst. mass. The amorphous bark layer of the com. product is a subsequent formation. The same probably also applies to the thin amorphous layers interspersed through the mass. (2) This benzoin consists essentially of cryst. conferyl benzoate together with some free BzOH and *d*-siaresinolic acid which originally forms with cinnamyl benzoate a thick cryst. magma, the latter finally becoming firm and hard through evapn. of the solvent. Slow oxidation of conferyl benzoate yields a small amt. of vanillin. (3) The benzoates of benzo-resinol and siaresinotannol reported by Ludy do not in fact exist. (4) Siamese benzoin is, contrary to the belief of Tschrech and Ludy, readily saponifiable. A small amt. of free conferyl alcohol in the resin is apparently due to the spontaneous decompn. of conferyl benzoate, possibly through participation of a little H₂O. On dry heating at 120° to 130° this benzoate loses 1/2 of the BzOH. (5) The colored glacial bark layer of the com. product is formed by passage of cryst. conferyl benzoate into the amorphous type, through simultaneous oxidation and polymerization. This change is effected by protracted storage at the ordinary, more quickly at elevated, temp. (6) On treating Siamese benzoin with solvents, a very large part of the cryst. conferyl benzoate becomes amorphous. (7) Siamese benzoin is formed

by the morbid action of the diseased cambium, carrying compds. of coniferyl alcohol, which is normally expended in the lignification of the cells walls. W. O. E.

Seed of *Datura alba* Nees. H. DIETERLE. *Arch. Pharm.* **264**, 140-64 (1926).—A study has been made of the oil (123 g.) extd. from the seed (950 g.) by C_6H_6 , Et_2O , trichloroethylene and AcMe. The clear product thus obtained had a dark green or brown color, was thickly liquid at the ordinary temp., depositing a cryst. ppt. at 10° and acquiring a salve-like consistency at 0° . The consts. detd. were: d_{15}^{40} 0.9250; n_D^{40} 1.5144; acid no. 20.35; ester no. 172.5; fatty acids free 10.14, total 95.65%; Hehner no. 93.6; Reichert-Meissl no. 2.41; Polenske no. 0.41; I no. 98.36; acetyl no. 10.2, unsaponifiable 2.9%. 100 g. of the oil consisted of palmitic and other solid fatty acids 6.18, caproic acid 1.00, α -linolic acid 23.55, β -linolic acid 2.92, oleic acid 60.86 g. W. O. E.

Influence of sodium hydroxide on the adsorption of arsenious acid by saccharated iron. L. HERBOTH. *Arch. Pharm.* **264**, 181-6 (1926).—The adsorption of As_2O_3 by saccharated Fe is markedly affected by NaOH. This adsorption capacity of com. saccharated Fe is lowered by the addition of HCl. Samples prepd. via the Ger. Pharmacopoeia develop with age a min. adsorption capacity, due probably to the action of atm. CO_2 . Further addn. of NaOH effects restoration of the adsorptive power. After addn. of about 0.5% NaOH more than the official requirement, the max. adsorptive power for the stored product is reached. The question whether a part of the originally incorporated NaOH is converted into carbonate remains open. The amts. of alkali leading to the formation of NaH_2AsO_3 and Na_2HAsO_3 show an apparent break in the adsorption curve, the highest value of which corresponds closely to disodium arsenite. W. O. E.

New drugs and pharmaceutical specialties during the year 1925. F. ZERNIK. *Pharm. Ztg.* **71**, 249-52, 279-80, 294-6, 314-6 (1926). W. O. E.

Reagent for the recognition of inferior neoarsphenamine. A. KIRCHER AND F. V. RUPPERT. *Pharm. Ztg.* **71**, 264-5 (1926).—Controversial with respect to the reagent "strontiuuran" as applied to arsphenamine and neoarsphenamine (cf. Kolle, Bauer and Leupold, *C. A.* **20**, 261; Hirsch, *C. A.* **20**, 646). The authors conclude from recent expts. that this reagent is useless insofar as the detection of inferiority in neoarsphenamine is concerned. W. O. E.

Compound of pyramidone and volutal. PAUL PFEIFFER AND OLGA ANGERN. *Pharm. Ztg.* **71**, 294 (1926).—Equimol. proportions of pyramidone and volutal unite when fused together or dissolved in ligroin, EtOH or H_2O to yield a definite compd. (needles from ligroin) m. $75-6^\circ$, and separable again into its components by treating the powdered substance for 10 min. with 10% HCl and filtering the dissolved pyramidone from the insol. volutal. W. O. E.

Digitalis preparations. RAPP. *Pharm. Ztg.* **71**, 312-4 (1926).—A presentation of the knowledge a druggist should possess in order properly to prep. digitalis powders, infusions, pills, suppositories, injections and tinctures on physicians' prescriptions. W. O. E.

Theory of the specific gravity of sirups. F. WRATSCHKO. *Pharm. Presse* **31**, 79-80 (1926); cf. *C. A.* **19**, 3349.—Various equations are discussed relative to the density of sirups, similar to the author's treatment of the theory of the sp. gr. of tinctures. W. O. E.

New diuretic. ABA SZTANKAY EDLER VON HERMANY. *Pharm. Zentralhalle* **67**, 113-5 (1926).—A new compd. of theobromine with Ca succrate is described, having the compn. $(C_7H_5N_4O_2)_2Ca(OH)_2 \cdot CaOC_{12}H_{21}O_{11}$, marked diuretic properties, and favorably affecting high blood pressure, weakened heart action and restlessness. W. O. E.

Acidimetric estimation of both components in mercury oxycyanide. E. RUPP. *Pharm. Zentralhalle* **67**, 145-6 (1926).—The method is based upon (1) the behavior of the oxycyanide toward HCl: $Hg(CN)_2 + HgO + 2HCl = Hg(CN)_2 + HgCl_2 + H_2O$ and (2) upon the behavior of the resulting cyanide and chloride toward $Na_2S_2O_3$: $Hg(CN)_2 + 2Na_2S_2O_3 = Hg(S_2O_3)_2 + Na_2 + 2NaCN$ and $HgCl_2 + 2Na_2S_2O_3 = Hg(S_2O_3)_2 + Na_2 + 2NaCl$. In a beaker contg. 40 to 50 cc. warm H_2O dissolve 0.3 g. of the sample and 0.5 g. of NaCl, cool and add 2 to 3 drops of methyl orange, then run in 0.1 N HCl to a color change of yellow to orange; now add 1.5 to 2 g. of pure $Na_2S_2O_3$ and titrate further with 0.1 N HCl until the color reverts to rose. Pure $Hg(CN)_2$, HgO require an equal amt. of acid for each titration, or 12.8 cc. for 0.3 g. 1 cc. 0.1 N HCl = 0.0108 g. HgO and 0.0126 g. $Hg(CN)_2$, resp. W. O. E.

Separation of cinchona alkaloids. J. MESSNER. *Pharm. Zentralhalle* **67**, 146-8 (1926).—With 1% aq. solns. of the salts and a 5% soln. of Na_2HPO_4 , on adding 3 drops

of the reagents to 10 cc. of the alkaloidal soln. The color is brown, as noted. 1. No immediate nor subsequent turbidity or cloudiness, or precipitate is noted. 2. (in the course of $\frac{1}{2}$ min.) turbidity or ppt. develops, which disappears on shaking. 3. On addition of a reagent develops a cloudiness which disappears on shaking. 4. On addition of a reagent tinge between the two, acidify 90 cc. of the alkaloidal soln. with 1 drop of 25% HCl, and mix 10 cc. thereof with 10 cc. of reagent. 5. With 1 drop of 25% ppt. indicates quinine, while the absence of any turbidity or ppt. even after standing indicates quinidine. Application of these observations to com. operations suggested.

Wolfsmilk as skin irritant. A. NESTLER *Pharm. Zentralhalle* 67, 161 (1926). A study has been made of the latexes of various species of domestic wolf-milk relative to their irritating effect upon the skin. The irritating substance of *Lithosaurus scopolii* is insol. in H_2O , easily sol. in Et_2O , C_6H_6 , $EtOH$, $CHCl_3$, slowly sol. in oil of turpentine, colored brown-red in concd. H_2SO_4 , also in concd. HNO_3 , all properties characteristic of resins. The activity of the latex seems to be more or less seasonal, that of Aug. and Sept. producing dermatitis, while the latex of Apr. and May was inactive. Of other species examd., *T. lathyris scopolii* was inactive, *T. populi Gaurmo* in 1 of 3 cases applied only produced transitory itching dermatitis, *T. pilosopus scopolii* as in the preceding, *T. platyphyllus scopolii* mild dermatitis, *T. calva scopolii*, none.

Microchemical reactions of tutocaine. L. ROSENTHALER *Pharm. Zentralhalle* 67, 177-9 (1926).—A study was made of the behavior of tutocaine, $pH.NC_6H_4.CO.CHMeCHMeCH_2NMe_2.HCl$, toward the reagents $PtCl_4$ (1), $AuCl_3$ (2), K tetratritro diammine cobaltite (3), KI (4), trinitroresorcinol (5) and $HgCl_2$ (6), and compared with procaine and cocaine under like conditions. Thus (1) produces, with the 3 alkaloids the following phenomena in the order named: droplets changing into bundles of needles; cryst. aggregates of notched rods or plates, possibly with or following the formation of droplets; cryst. aggregates of feathery forms following an amorphous stage. (2) Droplets changing into branching forms, droplets then clusters of rods more or less notched; amorphous changing to cryst. forms, dendritic or thread-like clusters; (3) clusters of prisms and plates with oblique end surfaces, also sep. prisms, clusters of prisms with needles; clusters of long needles and spikes, (4) droplets changing into (monoclinic?) prisms, droplets then cryst. clusters, droplets sometimes followed by needles, rods and spikes; (5) granules then cryst. clusters developing into notched forms; granules, then drusy forms changing into clusters and bundles of long needles with more or less feathered ends, seldom clusters of small prisms, amorphous then fungoid forms; (6) droplets no crystals observed, droplets becoming cryst. (separate prisms or branching aggregates); droplets, then granules, crystals not observed.

Reaction of alkaloids with furfural-sulfuric acid. L. EKKERT *Pharm. Zentralhalle* 67, 179 81 (1926).—A mixt. of 1 g. of an aq. 1% furfural soln. with 10 g. concd. H_2SO_4 constituted the reagent, 3 to 4 drops of which were applied to 1 to 3 g. of the alkaloid in a porcelain dish. Only in the case of veratrine did any striking color develop at ordinary temp. If, however, the dish be carefully warmed over a small flame, there is observed not only with veratrine but with atropine, novatropine, scopolamine, hyoscyne, colchicine, codeine, ethylmorphine and also antipyrine the development of brilliant colors. In the case of the alkaloid HBr , as scopolamine- HBr and hyoscyne- HBr , dissolve 0.02 to 0.03 g. of the salt in H_2O , treat with a little $NaOH$ soln. and ext. with 2 to 3 cc. of Et_2O , evap. the org. solvent in a porcelain dish and apply the reagent as above. β -Eucaine, caffeine, theobromine, cocaine, strychnine, brucine, pilocarpine and physostigmine yield no unusual color. Papaverine dissolves notably in warm concd. H_2SO_4 with a violet color. The colors developed on warming with the above reagent are in the case of atropine: intense violet red, novatropine: bright blue changing to dark green with continued heat, scopolamine: intense violet red, hyoscyne: intense violet red; veratrine (immediate blue, olive green, dark green, dark blue, finally violet) on heating wine-red, intense cherry-red, violet red, finally intensely dark red, yellow on diln. with H_2O ; colchicine: (yellow, brown yellow), on warming immediate yellow, green and finally brown; quinine: violet stripes, morphine (reddish) reddish then green and finally brown; codeine: like morphine, blue on diln. with H_2O , ethyl-cherry-red, finally violet red; codeine: like morphine, blue on diln. with H_2O , green with morphine: like codeine; apomorphine (reddish) dark red, green with H_2O , green with caustic alkali becoming red on shaking, antipyrine: evap. on ted. blue red, finally mulberry-red, shaken with $CHCl_3$ and H_2O , former yellow latter violet. To atropine scopolamine and hyoscyne the reagent is highly sensitive.

Standards of Bulgarian rose oil. M. SIEFANOVA *Rec. inst. *Académie des sciences**

Bulgarie 3, 30-52(1924).—In order to obtain results representative of pure Bulgarian oils, the investigation was extended over a period of 3 years at 4 of the chief production points and involving the different climatic and soil conditions. Distn. was carried out in the small village retorts, in the usual manner, on both the red (*Rosa damascena* Mill) and white (*Rosa alba* L) separately, in order to det. any difference in const. of the 2 sorts. Typical of the recorded results for oils from red and white roses, resp.: d_{15}^{20} 0.8523, 0.8584 during 1921; 0.8622, 0.8668 during 1922. Solidification point 17.0, 21.4°; 15.4, 16.6° n_D^{20} 51.7, 53.25; 56.25, 60.4; α -3.24, -1.56; -2.35, -1.32°. Acid no. 0.859, 0.747; 1.152, 0.921. Ester no. 7.65, 7.467; 8.933, 7.258. Sapon. no. 8.509, 8.214; 10.085, 8.179. Ac no. 205.84, 225.87; 245.11, 249.76. Free alc. as geraniol 64.02, 71.84; 78.952, 81.525%. Total alc. 66.127, 73.9; 81.412, 83.52. Color yellow. Numerous const. are recorded covering the operations of associated distns. for the years 1922, 1923 and 1924. The limits of const. over this period were: d_{16}^{20} 0.8494-0.8586 (1922), 0.8436-0.8634 (1923), 0.8550-0.8619 (1924). Solidification temp. 17-22.1, 15.5-22.1, 15.2-19.4°; n_D^{25} 52-53.6, 45.8-54.85, 49.4-52.1; α -1.74-3.17, -1.9-4.54, -2.94-3.61°. Acid no. 0.886-2.122, 0.712-3.021, 0.767-2.81. Ester no. 7.07-6.678, 6.505-11.36, 6.587-8.281. Sapon. no. 8.268-11.804, 7.426-13.446, 7.73-11.091. Ac no. 211.05-224.1, 196.97-237.38, 216.24-233.74. Free alc. 66.09-70.25, 61.17-74.84, 67.76-85.32. Total alc. 68.121-72.807, 63.1-77.97, 70.04-77.13%. The investigation is being continued. W. O. E.

The alkaloids of *Ceanothus americanus*. A. H. CLARK. *Am. J. Pharm.* 98, 147-56(1926).—*C. americanus* contains a complex mixt. of alkaloids. Methods of extg. them are discussed. One cryst. alkaloid was isolated. The reactions of the alkaloids, both the mixt. of amorphous ones and the cryst. one, towards a no. of alkaloidal precipitants has been recorded and photographs of the few cryst. ppts. obtained, all from the cryst. alkaloid, have been made. The common color tests were tried but no characteristic reactions were obtained. An interesting resin-like substance is mentioned. W. G. GAESSLER

Application of micro methods to control work in pharmaceutical manufacturing. W. FIGDOR. *Am. J. Pharm.* 98, 157-62(1926); cf. *C. A.* 19, 2791.—F. reports methods and results on the detn. of alk. earth salts of org. acids, quant. micro ash detn. of drugs, detn. of residues in tinctures and fluid exts., detn. of esters and menthol in oil of peppermint, detn. of non-volatile extractive sol. in ether or petroleum ether, and detn. of alkaloids in drugs and alkaloidal preps. W. G. GAESSLER

The instability of the sodium perbenzoate. A. J. GELARIE AND F. R. GREENBAUM. *Am. J. Pharm.* 98, 163-6(1926).—The compd. has the tendency to give off O and is transformed into the more stable $BzONa$: $C_6H_5CO_2O_2Na \rightarrow C_6H_5COONa + O$. This O is in the *status nascendi* and has a very great oxidizing power. On standing the soln. loses its activity, that is the free O decreases more and more so that after standing for 2 days only Na benzoate is left. The decompn. is accelerated by the presence of foreign substances. A characteristic reaction for this compd. which can be used to det. the degree of decompn. is its behavior towards KI. The pure compd. dissolved in H_2O is decompd. in 24 hrs. to about 95% and after 48 hrs. the decompn. is complete. W. G. GAESSLER

Comparative anatomy of the roots and rhizome of Solanaceae of importance in pharmacognosy. Localization and determination of the alkaloids. ERICH LEWINSKY. *Botan. Arch.* 6, 312-33(1924); *Botan. Abstracts* 14, 880.—The chief places of storage of the alkaloids in the roots of Solanaceae are the epidermal and subepidermal layers. Because of its alkaloidal contents, the rhizome of *Scopolia* species can be used for the same purposes as belladonna roots. The alkaloidal content surpasses that of belladonna roots. The content of alkaloids in the roots of *Mandragora vernalis* is less than that in *Scopolia* species but above that of belladonna. The rhizome and roots of *Physalis alkekengi* contain no alkaloids. The solanine content of the roots of *Solanum dulcamara* agrees with that in the roots of this plant. H. G.

A pharmacognostical study of *Chenopodium ambrosioides* Linnaeus from the Philippines. J. K. SANTOS. *Philippine J. Sci.* 28, 529-48(1925).—For microchem. tests, in order to note the parts of the plant in which the oil is secreted and stored a 5% alc. KOH soln. was found to be preferable to a freshly prepd. alkanet tincture, osmic acid, Sudan red and an aq. soln. of $Cu(OAc)_2$. The oil of chenopodium is confined largely to the glandular hairs of sac-like shape; some is found in the embryo. The oil-bearing hairs are especially abundant on both sides of the leaves, on the upper half of the ovary, when this is nearly mature, in the crevices between the ridges of the young portion of the stem, and on the surface of the calyx. In order to secure a greater

yield of oil, the entire plant, with the exception of the old part of the stem should be utilized before the fruits and leaves become too mature. The favorable time for distn. would appear to be after the most of the flowers are open. ANTON HOGSTAD, JR.

Some further remarks on tobacco cultivation for nicotine. J. VERNELL CUTLER, J. J. THERON AND J. DU P. OOSTHUIZEN. Dept. Agr. Union S. Africa, *Bull.* 2, 23 pp. (1925).—The max. nicotine content of whole plants of *Nicotiana glauca* varied from 2.79 to 4.79%. The leaves, constituting 45 to 55% of the air-dry plant, contained from 5.4 to 8.2% nicotine for 8 plants. The nicotine content of the leaves increased continuously to a max. at about 88 days after transplanting and then decreased rapidly. The stalks and pods, constituting 25 to 45 and 18 to 25% of the whole plant, contained 0.79 to 1.20 and 0.65 to 1.39% nicotine, resp. The seed contained 0.00 to 0.06% and the roots 0.29 to 0.71%. "Topping" increased the total nicotine content 10 to 50%, the greatest increases occurring in the leaves. Green sweating followed by air-drying appeared to be the most economical method for treating the plants to obtain a high yield of nicotine although flue-curing gave the best results. In general the highest percentages of nicotine were obtained in the first cutting followed by slight decreases in the second and third. Application of complete fertilizers appreciably increased the total yield of nicotine but had little effect on the percentage content of the plant while heavy applications of N fertilizers had little effect in either case. K. D. LISON.

Iodotannic acid with reference to the preparation of the sirup. EVAKISIO GAM BETTA. *Boll. chim. farm.* 65, 33-6 (1926).—Iodotannic acid was prepd. in nearly quantitative yield by heating to 60° a soln. of 4 g. tannic acid, 2 g. I, 1 g. KI in 100 cc. water with Na_2PO_4 and $\text{Ca}_3(\text{PO}_4)_2$ 2 g. each. The 1, 30% is chem. combined. The taste of the sirup is pleasant, not astringent. MARY JACOBSEN.

Baroni's reaction in neutral glass for pharmaceutical uses. LUIGI TIRILLI. *Boll. chim. farm.* 65, 65-72 (1926), cf. C. C. 1, 20, 975.—Because of the great sensitiveness of hematoxylin the results are easily vitiated by impurities of the reagents, dust, fumes, vapors, etc. The great sensitiveness to Cu may often be misleading. It also is a delicate test for the decomposition of glass made up of silicates only and containing bases or heavy metals. It fails entirely in the case of borate glass, the decomposition of which can be detected with phenolphthalein. It does not indicate neutral salts or acids (SiO_2 , borosilicic acids) washed out of the glass. Its use in conjunction with phenolphthalein is recommended. MARY JACOBSEN.

Non-toxic insulin. CESARE PIAZZA. *Problemi di Nutrizione* 1, 120-4 (1925). *Ber. ges. Physiol. exp. Pharmacol.* 31, 68 (1925).—The non-toxic insulin, the prepn. of which is described elsewhere, is an amorphous, slightly yellow powder. It differs from Banting's insulin only in that it is thermostable (the soln. can be sterilized 15 min. at 120°), and that it does not produce the hypoglycemic complex even if the blood sugar is reduced to 0. A daily dose of 0.01 g. solid substance is sufficient. Actonuria and glucosuria disappear slowly under this dose, hyperglycemia is mitigated to a lesser degree. No untoward effects were observed except for irregular menstruation in some women. P. assumes direct stimulation of the pancreas. MARY JACOBSEN.

Solid petroleic ether extracts of flowers. M. J. VARD. *Partens de France* No. 36, 35-7 (Feb., 1926).—These exts. contain, besides the essential oil proper, a certain amount of vegetable waxes and coloring matters. The waxes at times act as excellent fixing agents for the perfume, but are only slightly sol. even in strong alc. The bulk of the wax can be removed by washing in alc., the residual portion acting as fixer without interfering with its soly. The total ext. and the essential oil content of the latter were detd. by extg. the flowers with petroleic ether, evapg. the solvent, steam distg. the residue till odorless, and recovering the oil from the distillate by extn. with ether. The following results were obtained, and figures obtained by Hesse and by von Soden are given for comparison:

	Oil per 1000 kg. of flowers		Total ext. per 1000 kg. of flowers	Yield of oil of extract
	Hesse	von Soden		
Jasmine	178 g.	770 g.	240 g.	3000 kg.
Orange	800 g.	660 g.	609 g.	2820 kg.
Roses (Grasse)	—	520 g.	683 g.	2400 kg.
Tuberose	60 g.	—	33 g.	0986 kg.
Violet (leaves)	—	20 g.	18 g.	1070 kg.

V.'s results are means of several detns. differing by not over 2-3%. There is fairly good agreement in the figures of the different experimenters, except for von Soden's results for jasmine, and V. attributes the discrepancy to the fact that von S. probably

started from a jasmine pomatum concentrate, instead of using the flowers themselves.

A. PAPINEAU-COUTURE

Anisaldehyde in perfumery. ANON. *Parfums de France* No. 36, 52-5 (Feb., 1926).—Brief review of its prepn. and properties, and of its use in perfumery. A. P.-C.

Absolute oil of tuberose. GUIDO ROVESTI. *Profumi Italiani* No. 9, 248 (1925); *Parfums de France* No. 36, 56 (Feb., 1926).—Three samples of the 1922, 1923 and 1924 crops gave the following results, resp.: d_{16} 1.211, 0.988, 1.061; rotation $-5^{\circ}41'$, $-1^{\circ}7'$, $-3^{\circ}15'$; ester no. after acetylation 168, 256, 217; methyl anthranilate 4-5%.

A. PAPINEAU-COUTURE

Oil of bergamot in 1924-1925. R. STAZIONE SPERIMENTALE DI REGGIO-CALABRIA. *Riv. ital. ess. profum.* 1925, No. 11, 127-9; *Parfums de France* No. 36, 56 (Feb., 1926).—The consts. given fall within the normal limits. A. PAPINEAU-COUTURE

Oil of nepetella. P. LIOTTA. *Riv. ital. ess. profum.* No. 11, 129 (1925); *Parfums de France* No. 36, 56 (Feb., 1926); cf. C. A. 19, 378.—Three samples of oil of nepetella (*Nepeta cataria* and *canescens*) distd. from plants from the Calatabiano district had d 0.9085 (at 18°), 0.9095 (at 15°), 0.9090 (at 15°); $[\alpha]_{20}$ $109^{\circ}35'$, $104^{\circ}37'$, $108^{\circ}25'$; b . p. 214° , 214° , 214.2° ; soly. in 80% alc. 1 vol., 1 vol., 0.95 vol.; residue on evapn. 4.8, 4.82, 4.72%; sapon. no. of the residue 157, 157, 155, resp. L. considers the oil consists largely of terpenes, is high in carvacrol (?), and contains an alc. for which he proposes the name *nepetol*, and also traces of pulegone and of thymol. A. P.-C.

First distillate from essence of thyme. Thymene. ANGE ADIDA and MAURICE DEMIGNEUX. *Bull. sci. pharmacol.* 33, 65-70 (1926).—Thymene is a term applied to that part of the essence of thyme which distils between 160° and 185° . Essences of *Thymus capitatus*, *T. vulgaris* and *T. serpyllum* yield distillates at $158-165^{\circ}$, $158-163^{\circ}$ and $155-160^{\circ}$, resp., contg. 3.2, 7.5 and 18.0% of pinene, resp., calcd. to the original essences. The first of these is dextrogyrous, the other two are levogyrous. Pinene is characterized by its yielding pinonic acid on treatment with permanganate.

L. W. RIGGS

Preparation of gentian violet for intravenous injection. VICTOR BURKE and JANE L. NEWTON. *J. Am. Med. Assoc.* 86, 529-34 (1926).—The conclusions of this study are given in 13 paragraphs. L. W. RIGGS

Pharmacy in Japan. T. NOZOE. *J. pharm. chim.* [8] 3, 41 6, 90-4 (1926).—A comprehensive survey, demonstrating the high plane occupied by pharmacy in Japan. S. WALDBOTT

"Cenomassa zyma." P. WEINREICH. *Schweiz Apoth. Ztg.* 63, 533-4 (1925)

A new pill mass for the rapid prepn. of non-hardening pills. It is a non-drying mixt. of purified powd. yeast dried at 120° and yeast ext., with addn. of a little NaCl. In taste it resembles meat ext., and causes digestive juices to flow, which assists in the resorption of unpleasant drugs, e. g., quinine, Fe, etc., given in pill form. (Cf. Heimz, *Verhandl. d. Congr. f. innere Medizin*, 1921.) Pharmacopoeial recognition of purified powd. yeast and yeast ext. for use in pill masses is recommended. S. WALDBOTT

Note on extractum belladonnae. R. MAEDER. *Schweiz Apoth. Ztg.* 63, 535 (1925).—A dried ext. prepd. by vacuum evapn., according to Pharm. Helv. IV, of an ext. of belladonna leaves stored for more than 6 yrs., gave as high as 4% total alkaloid. This result seems to favor vacuum evapn. of ext. of dried leaf, as against the use of fresh leaves and stabilization. An editorial note points out that pharmacol. keepn. qualities are as important as a high alkaloidal content. S. WALDBOTT

Determination of santonin in pastilli santonini cum saccharo. R. EDER and W. SCHNEITER. *Schweiz Apoth. Ztg.* 63, 557-61 (1925).—Kropat's method (C. A. 6, 2486) gives somewhat higher results on account of slight soly. of sugar (1 mg.) and tragacanth (1.8 mg.) in CHCl_3 (50 g.). Shake 4 very finely powd. tablets with 50 ml. CHCl_3 for 5 min., add 20 drops of H_2O , again shake for 0.5 min., filter, collect 45 g., distil off the CHCl_3 , dry the residue for 1 hr. at 100° , allow to cool in a desiccator and weigh. The limiting wts. of the residue should be 0.085-0.095 g., corresponding to a santonin content of 0.024-0.026 g. per tablet. Identify the santonin by its m. p. 170. S. WALDBOTT

Suggestions for the galenical preparations of Pharm. Helv. V. H. GOLAZ and K. SIEGFRIED. *Schweiz Apoth. Ztg.* 63, 593-6, 607-11, 625-9, 641-3, 657-9 (1925). cf. C. A. 17, 2346, 18, 151; 19, 2109.—A system of galenical preps. is suggested in which tinctures, wines, sirups, ointments, etc., of a given drug, potent or non-toxic, are prepd. by decimal diln. of a stabilized standard ext. of this drug, obtained by an internationally adopted uniform method. A synoptical table of potent exts. and galenical derivs., with graded alkaloidal contents, and max. doses is given; examples of non-toxic exts. are included. Ext. are of class A (fresh drug) or B (dried drug). To

prep. fluid exts. of *A*, press out the juice of the plant, repeat this after addn. of H_2O , then pasteurize for 30 min. at $50-65^\circ$ in presence of 15-25% EtOH, ppt. inert matter. With potent drugs, standardize the ext. by a chem. or physiol. method and adjust to the adopted % of active principle. To obtain a dry ext. of *A*, evap. the fluid ext. *in vacuo* at $25-40^\circ$ and bring to required strength by addn. of lactose or Na-IPSO_4 . For exts. of class *B*, dry the drug in a warm current of air at $25-35^\circ$ or more, obtain fluid exts. by the usual methods of extn. and dry exts. as under *A*. The manuf. of several exts. typical of these classes is described in detail.

The assay of aloes. R. EDER AND W. SCHNEITER. *Schweiz. Apoth. Ztg.* 63, 630-1, 644-5, 660-2, 669-71 (1925).—The assay consists in detn. of non-resin (Tschirch and Hoffbauer, 1905; Pharm. Helv. IV). Dissolve 1 g. powd. aloes in 5 cc. MeOH on a water bath under reflux, then add to the boiling soln. 30 cc. CHCl_3 in small portions, allow the stoppered flask to stand for 12 hrs., weigh its contents, filter into a tared flask, weigh an aliquot and distil off the solvent, pass a current of dry air through the flask on the boiling water bath for 20 min., dry for 1 hr. at 100° , cool in a desiccator and weigh, then calc. % of non-resin. Two com. samples gave 69.90, 70.10, 71.10, 70.84.10-84.45%; min. required: 80%. S. W. WARDEN.

Christian Bühner, 1849-1925. "C." *Schweiz. Apoth. Ztg.* 63, 689-91 (1925).—An obituary. S. W. WARDEN.

The value of microanalytical methods and examples of their application. G. L. KEENAN. *J. Am. Pharm. Assoc.* 14, 112-3 (1925).—Essay. The microscopical identification of plant ingredients, microchem. tests, optical crystallographic methods and quant. microscopy are discussed. L. E. WARREN.

Temperature effects on hypochlorite solutions of the Carrel-Dakin type, including the proposed U. S. P. X formula. I. A. BECKER. *J. Am. Pharm. Assoc.* 14, 129-32 (1925).—Hypochlorite solns. were made by each of several formulas from recently assayed CaOCl_2 . The solns. were assayed for Cl equiv. at once and again after storage under various conditions of light and temp. Dakin solns. may be heated to 50° without serious injury. Daylight is a stronger decomposing factor than heat. The observations on the U. S. P. X formula are that the gelatinous nature of the Ca phosphate ppt. holds some of the sol. hypochlorite so tenaciously that the amt. of H_2O is not sufficient to remove all of it, and that the filtration process is consequently too long and tedious. The CaCO_3 ppts. yield the sol. hypochlorite more readily and filtration is fairly rapid. L. E. WARREN.

Report on proximate analysis of Euphrasia. WM. F. MILLON AND L. E. SAYRE. *J. Am. Pharm. Assoc.* 14, 308-17 (1925).—The medicinal properties lie in the aromatic, resinous substance. Volatile oil is present. The tincture has a decided herb-like taste. Ash 8.6, moisture 10.1, acid-insol. ash 1.46. EtOH ext. 10.1, EtOH ext. (after EtOH) 13.6, H_2O ext. (after EtOH and EtOH) 9.9%, cellulose 11.1, albumin 10.3, tannin 1.84, EtOH ext. of drug 13.3%. Resinous substances and glucose are present in considerable amts. L. E. WARREN.

The influence of climatic conditions on the yield and quality of oil of *Mentha arvensis*, variety *piperascens*. G. A. RUSSELL. *J. Am. Pharm. Assoc.* 14, 679-81 (1925); cf. *C. A.* 19, 1753. Plants were grown at 6 locations and the oil was distd. from each. The yields of combined and free menthol were detd. The altitudes, soil types, rainfall, mean temp., etc. were noted. An attempt to discover the causes for the variation in the compn. of the oil from season to season failed. It is believed that plants grown in the sun give higher yields of oil than do others. L. E. WARREN.

Notes on pepsin preparations. C. C. GLOVER AND C. G. FESS. *J. Am. Pharm. Assoc.* 14, 682-6 (1925); cf. *C. A.* 17, 3568. It is again shown that the presence of free acid in considerable amts. tends to accelerate the loss in pepsin preps. A very small amt. of acid is necessary for preservative, but the amt. is much less than the U. S. P. prescribes. Preps. were made contg. various substs. which it was thought would act as preservatives. Caffeine Na salicylate, Me salicylate and Na phosphatide in varying proportion were added to the pepsin prepn. All of the preps. were assayed and were allowed to stand for 6 mo. They were then re-assayed. Some were nearly of full strength, but most had depreciated considerably or had completely lost their activity. There appeared to be no consistent explanation of the behavior of specimens contg. preservatives. From expts. in dialyzing sols. of pepsin it is apparent that pepsin is composed of but one enzyme. In curdling milk by pepsin casein, Ca salts and acid appear to be essential. L. E. WARREN.

A new emulsifying agent for volatile oils. C. H. LAWALL. *J. Am. Pharm. Assoc.* 14, 703-4 (1925).—A mixt. of 20% of powd. egg albumin and 80% of powd. K bitartrate

is an excellent emulsifying agent for volatile oils. For oils heavier than H_2O , such as sassafras or wintergreen, place 100 g. of oil in a 200-cc. bottle, add 1 g. of the emulsifying mixt. and agitate well. Then add 100 cc. of H_2O and shake violently for 1 min. The emulsions stand well. For oils lighter than H_2O use 2.5 times the amt. of emulsifying mixt. This emulsifying mixt. is particularly useful for prepg. concentrates for adding to sirups in the carbonated-beverage industry. Immiscible liquids like $CHCl_3$, Et_2O or C_6H_6 do not emulsify well with the mixt. and fixed oils do not emulsify as well as with other emulsifying agents.

L. F. WARREN

Ether studies. III. The quantitative determination of aldehyde as a contaminant. E. P. PHELPS AND A. W. ROWE. *J. Am. Chem. Soc.* **48**, 1049-53(1926); cf. *C. A.* **18**, 3254.—A method based on the use of Schiff's reagent is described for the quant. detn. of aldehyde in Et_2O which allows the estimation of min. amts. of the order of 0.003%.

C. J. WEST

Therapeutic organic mercury compounds. WELLCOME FOUNDATION, LTD., T. A. HENRY AND T. M. SHARP. *Brit.* 237,735, Aug. 12, 1924. Products sol. in oils, fats and artificially prepd. fatty acid esters are prepd. as follows: (1) 2-hydroxy (or acetoxy) mercuri-3-hydroxybenzaldehyde is warmed with caproic acid and allowed to cool; 2-caproxymercuri-3-hydroxybenzaldehyde seps. Caprylic, lauric, myristic, oleic and chaulmoogric acids give similar products. (2) *p*-tert-Butylphenol is boiled with $Hg(OAc)_2$ and the resulting 2,6-diacetoxymercuri-*p*-tert-butylphenol treated with lauric acid to yield 2,6-dilauroxydimmercuri-*p*-tert-butylphenol. Other phenolic substances such as carvacrol, thymol and *p*-isoamylphenol may also be used and other higher fatty acids may be substituted for lauric acid. (3) 2-Hydroxy(or acetoxy)-mercuri-3-hydroxybenzaldehyde is dissolved in NaOH soln. or the Na salt is dissolved in H_2O and treated with caprylic acid to effect pptn. of 2-capryloxymercuri-3-hydroxybenzaldehyde.

Bismuth phosphatide compounds. CHEMISCH-PHARMAZEUTISCHE AKT.-GES. BAD-HOMBURG. *Brit.* 237,912, July 29, 1924. Bi compds. are caused to react upon phosphatides such as lecithin to obtain products adapted for treating syphilis. Lecithin may be used with Bi quinine iodide, Bi cholate, the Bi salt of 2-phenylquinoline-4-carboxylic acid and the Bi salt of trichlorobutyl malonate. The products may be mixed with oils and used for injection.

Medicine for treating arteriosclerosis. V. MLADJEVSKY. U. S. 1,579,828, April 6. Finely ground *Drosera* is subjected to extrn. with a soln. of Na silicate, while avoiding pptn. of SiO_2 , and the soln. is inspissated *in vacuo* to a concn. at which the SiO_2 only just remains in soln. The product contains the *Drosera* enzymes in active condition.

Heart-affecting glucoside from bulbus scillae. E. SUTER. U. S. 1,579,338, April 6. An aq. ext. of squills is shaken with an immiscible org. solvent such as $CHCl_3$, mixed with MeOH in order to remove the glucoside from the ext. in the form of a compd. with natural tannin, the soln. is evapd. *in vacuo* to dryness at a low temp., the residue is dissolved with H_2O and an org. solvent such as MeOH and the glucoside is liberated by the addition of Pb subacetate or other tannin-pptg. agent. After filtering, the excess tannin-pptg. agent is pptd. and the sepd. soln. evapd. to dryness *in vacuo* at a low temp. and the glucoside in the residue is selectively dissolved by a solvent such as $CHCl_3$ contg. 5% MeOH.

Laxative choline compound. J. CALLSEN. U. S. 1,580,012, April 6. $AcOCH_2CH_2OCH_2CH_2NMe_2$, treated with MeBr in C_6H_6 gives the methobromide, a white cryst. powder, easily sol. in H_2O and alc., almost insol. in ether, m. 126-8°. It may be used subcutaneously as a laxative. Cf. *C. A.* **19**, 560.

Medicinal composition. G. L. COUSINEAU. U. S. 1,579,086, March 30. A liquid mixt. for hypodermic use comprises sol. and insol. portions of the whole parathyroid gland comminuted to a substantially impalpable condition and mixed with a physiological salt soln.

Killing microorganisms. W. RUPPEL. U. S. 1,577,659, March 23. Cultures for vaccine manuf. or other material contg. microorganisms is subjected to the action of an elec. current between diaphragms which sep. the electrodes from the material under treatment.

Acridinium compounds. I. BENDA AND O. SIEVERS. U. S. 1,577,415, March 16. Hydroxy-10-alkylacridinium compds. which are good antiseptics are prepd. by heating hydroxyacridines with alkylating agents in the absence of acid-binding substances. Cf. *C. A.* **20**, 95.

Composition for sterilizing toothbrushes, etc. V. J. M. THESER. U. S. 1,579,413, April 6. See *Brit.* 216,464 (*C. A.* **19**, 154).

Denicotinizing tobacco. H. W. SMITH. U. S. 1,577,768, March 23. Tobacco is treated with live steam at a temp. above 100° and under superatm. pressure and with NH_3 and then extd. with an org. solvent such as C_6H_6 .

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

The gypsum-sulfuric acid process of the Farbenfabriken vorm. Friedr. Bayer and Co. W. J. MÜLLER. *Z. angew. Chem.* 39, 169-74 (1926). — See C. 1 20, 970.

Catalytic ammonia oxidation. L. ANDRUSSOW. *Z. angew. Chem.* 39, 321-32 (1926).—A lab. study of the reaction between NH_3 and O_2 in air with Pt gauze as catalyst. An air mixt. contg. 8.3% NH_3 was passed through Pt gauze (3000 meshes per sq. cm., 0.04 mm. wire) set in a heated quartz tube. The temp. was measured with a thermocouple close to the Pt on the downstream side. The rate of flow of the gas mixture was varied within wide limits giving times of catalytic contact from 2×10^{-4} to 100×10^{-4} sec. Below 500° some free NH_3 escapes the catalyst. Above 600° the product is mainly NO , mere traces of NH_3 . Below 600° the yield of NO (less than 50%) is nearly independent of the time of contact. Above 600° the yield of NO at any fixed temp. increases rapidly as the contact time decreases. A yield above 90% is obtained only at temps. above 750° and time of contact less than 3×10^{-4} sec. The decomposition of NH_3 and NO , their interaction and other possible side reactions are discussed.

The chlorination of metals. P. S. BRALLIER. *Trans. Am. Electrochem. Soc.* 49, (preprint) (1926).— SiCl_4 is prepd. by passing Cl over a mixt. of 90% Si and SiC . The furnace consists of a steel or cast-Fe shell cooled by a H_2O spray and lined with C slabs. The condensers are flushed with cooled SiCl_4 liquid to prevent choking by FeCl_3 and AlCl_3 . TiCl_4 is prepd. similarly from titanium carbonitride contg. 70-75% Ti . SiCl_4 is immediately decomposed by H_2O but TiCl_4 can be dissolved under proper conditions. Sn reacts readily with Cl at 100° to 111° , but does not react when molten. When Sn is exposed to Cl gas, the exothermic reaction melts down the metal. The process adopted is to pass Cl into a bath of fused SnCl_4 in which Sn is submerged, a little S being added to the bath. SbCl_3 is prepd. by exposing metallic Sb to Cl in a chamber cooled by H_2O . ZnCl_2 is produced by passing Cl into molten Zn at 500° , the chloride floating on the surface and being tapped off. This is a bluish gray product which contains ZnO and finely divided Zn . It can be purified by distn., giving a white product.

Chemistry of bleaching powder. SHUTCHIRO OCHI. *Trans. Am. Electrochem. Soc.* 49, (preprint) (1926).—The principal constituent of bleaching powder has a crystal form, although an amorphous variety may be present in some of the product. Its constitutional formula is probably $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$. This is proved by microscopic researches, by the measurement of the heat of soln., and by the heat of hydration and the aq. vapor tension of the crystal. The heat of soln. of crystd. $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$ is 7530 cal., that of $\text{Ca}(\text{OCl})\text{Cl} \cdot 9830$ cal. The heat of hydration is, therefore, 2300 cal. The aq. vapor tension of crystals of bleaching powder at 30° , 20° and 10° , is 7.99 mm., 3.93 mm. and 1.80 mm., resp. The mechanism of bleaching powder formation is considered to be: at first an amorphous mass of mixed Ca salts of HCl and HClO and water is formed, then crystals of $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$ sep. out. When the chlorination is carried out at higher temp. and quickly finished by cooling, the product is chiefly of the amorphous nature, while slow chlorination at lower temp. favors the formation of the crystal variety. Presence of an excess of water retards the crystal development of the crystal variety. The amorphous variety has less stability and is more easily decomposable by CO_2 than the crystal variety. From the reaction between H_2O and bleaching powder, the heat of formation of $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$ are exothermic, while the Cl -forming decompos. are endothermic reactions. The heat of formation of $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$ from slaked lime and Cl is calcd. to be +12,120 cal. The equl. pressures of O and Cl over $\text{Ca}(\text{OCl})\text{Cl} \cdot \text{H}_2\text{O}$ are computed by applying Nernst's heat theorem.

Optimum temperature and time conditions for the preparation of sodium sulfide by fusing sodium sulfate with coal. Recovery of sodium thiosulfate as a by-product. M. MINAIKOV. *Mitt. Wiss.-techn. Arbeiten Republ. (Russ.)* 13, 90-6 (1924).—Best yields of Na_2S were obtained by the use of 1 pt. of coal to 4 pts. of Na_2SO_4 , a furnace temp. of $700\text{--}800^{\circ}$, and a time of treatment of 45 min. Longer heating rapidly

reduces the yield. If wood charcoal, with its lower ash content, is used, the temp. should be 800-900°. The disappearance of the flame, which develops 5-6 min. after the crucible is placed in the furnace, is evidence that the reaction is complete. The melt should be porous and pink in color with greenish specks. After lixiviation of the melt and sepn. of cryst. Na_2S , SO_2 may be passed into the mother liquor, when reasonably pure $\text{Na}_2\text{S}_2\text{O}_3$ is obtained. B. C. A.

The active carbons of Edouard Urbain. H. CHAUMAT. *La nature* 54, i, 149-55 (1926).—A description with diagrams and illustrations of the manuf. of active C, and its properties and com. uses. C. C. DAVIS

Preparation of an ash-free wood charcoal. L. H. REYERSON. *Ind. Eng. Chem.* 17, 1114(1925); 18, 213(1926).—Coconut shells cleaned superficially, broken up and extd. in a Soxhlet app. for 48 hrs. with Et_2O , and similar lengths of time with EtOH and H_2O , then dried and coked as usual, showed an ash content of 0.4% (chiefly SiO_2), and gave an aq. ext. practically neutral. W. C. EBAUGH

Methods of revivifying inorganic decolorizing powders. LEOPOLD SINGER. *Chem.-Ztg.* 50, 4-5, 57-8, 64-5, 74-6(1926); cf. C. A. 15, 311, 1212; 18, 887, 2062, 2446, 2802, 2958, 3270; 19, 2, 157, 394, 726, 878, 1760, 1970, 2393, 3372.—A collective review of the work carried out to revivify decolorizing carbons, fuller's earth, silica gel, etc., referring to foreign and U. S. patents. The Brockway roasting app. for fuller's earth (U. S. 978,625) is described. S. points out that much work is yet to be done in this field and contributes the present review as a basis for future work. D. THURSEN

Bleaching action of fuller's earth. O. ECKART. *Seifensieder-Ztg.* 53, 154-5, 169-70, 187-8(1926).—The differences in the bleaching quality of Bavarian earths lie principally in the degree of their purification. Small amts. of acidity increase their activity but large amts. hinder it. The max. bleaching effect is generally obtained in 10-30 min.; it is a purely physical phenomenon, because the first percents of earth are much more effective than the later ones and because some of the color can often be removed from the oil by anhyd. alc. The reason why absorbed coloring matters cannot be completely removed by solvents from spent earth is their change in size upon the earth. A chem. action may occur as a secondary effect when deposited impurities may react with the small amts. of FeCl_3 or AlCl_3 , thereby blackening the earth. Activated earths can remove acidity, especially from mineral oils. In the manuf. of activated neutral earths CaCO_3 is added. In storage this reacts with the chlorides or sulfates of Fe and Al, forming hydroxides, which cover the active surface of the earth, decreasing activity and thus give rise to the observed phenomenon of "aging"; properly washed earths do not show such aging. The activity cannot be due to electrically charged particles, since there are always some electrolytes present which by absorption of H_2O from the air would soon cause a discharge of these particles. P. ESCHER

Increasing the internal volume of silica gels by moist heat treatment. H. N. HOLMES, R. W. SULLIVAN AND N. W. METCALF. *Ind. Eng. Chem.* 18, 386-8(1926).—"A method is described for greatly increasing the adsorptive capacity of gels by checking the initial slow drying at a water content of approx. 60%, allowing the partly dried gels to synerize for a week or two in closed vessels and then boiling a few hours in dil. acid before washing and final drying. The method is general, but is applied particularly to the gelatinous ppt. obtained by addn. of FeCl_3 soln. to water-glass soln. In this case the boiling acid removes the Fe_2O_3 , leaving somewhat hydrated SiO_2 as a white, highly porous gel." F. L. BROWNE

The future demand for bromine. C. R. DELONG. *Ind. Eng. Chem.* 18, 425-8 (1926).—Statistics for the production of Br during 1900-1925 showed a marked increase in demand in 1924, probably due to the anticipated use in making "lead tetraethyl gasoline." As the du Pont Company shifted its process from EtBr to EtCl it is likely that hereafter Br will be used only in $\text{C}_2\text{H}_5\text{Br}$, etc., as carriers. Of a potential demand of 9,000,000 lbs. in the U. S. A. (about 3 times the max. consumption in 1924), 5,000,000 lbs. could be supplied from Saginaw Valley, Mich. Recovery from sea water offers the greatest immediate possibilities; about 1800 gal. of sea water yields a pound of Br. Other sources of Br are brines at Pomeroy, Ohio, and Kanawha, W. Va.; solar evapn. of sea water at San Diego Bay, Cal., and brines of the west. In Germany 40,000,000 lbs. of Br could be obtained annually from potash operations at Stassfurt—about ten times the max. heretofore produced. France and her colonies, the Dead Sea and other saline deposits swell the potential resources. No shortage of Br is feared, even in view of increased demands by reason of prospective consumption of "leaded gasoline." W. C. EBAUGH

Production and consumption of sulfur. B. SEGERFELT. *Svensk Pappers-Tid.* 28, 505-7(1925).—The occurrence of S in Japan is compared with the world's needs.

Japanese localities are listed; prices, export points and freight rates are given.

Sodium and its use. P. HOLMSEN. *Teknisk Ukeblad* 1923, 452-3, *J. Inst. Metals* 33, 501-2.—A short account of the world's production of Na and the phys. and chem. properties of this metal. Only the electrochem. methods of manuf. are said to be of any importance. Most of the Na is used in the manuf. of NaCN for extg. Au from its ores. Other important uses are in the manuf. of peroxide for bleaching purposes and for disinfection and as metal or amide in the dye industry. As a reducing element Na is used in the manuf. of some uncommon elements, such as Ta and B. During the war Na was to some extent used for bearing metals.

Cobalt and its recent applications. L. GUILLET. *Rass. min. met. chim.* 64, 33 G (1926).

Silica in 1924. F. J. KATZ. Bur. of Mines, *Mineral Resources of U. S.*, 1924, Part II, 183-6 (preprint No. 16, published Mar. 19, 1926).

Gypsum in 1924. K. W. COTTRELL. Bur. of Mines, *Mineral Resources of U. S.*, 1924, Part II, 231-40 (preprint No. 19, published Mar. 27, 1926).

Antimony in 1924. F. C. SCHRADER. Bur. of Mines, *Mineral Resources of U. S.*, 1924, Part I, 105-18 (preprint No. 10, published Mar. 13, 1926).

Modern production of imitation pearls. G. DUROCHER. *La nature* 54, 1, 161 G (1926).—An illustrated description, including the chemistry involved.

Annual review for 1925 of progress in the manufacture of plastic materials with casein as a base. O. MEIER. *Caoutchouc & gutta-percha* 23, 13062 3 (1926).—Chiefly patents.

Washing and sizing sand and gravel. EDMUND SHAW. *Trans. Am. Inst. Mining Met. Eng.* 1926, No. 1528-H, 10 pp.—A review, mentioning the impurities to be washed out, a standard washing method, and means of detg. the water required for washing by decantation. Special washing methods for removal of liquid and shale, film, clay, trash, etc., are outlined. The sand and gravel market is demanding more and more from the producers in the no. of sizes and the efficiency of screening.

HERMANN, C.: *Einführung in die Kaliindustrie.* Halle W. Knapp 136 pp. R. M. 5.70.

Distilling persulfuric acid and solutions of persulfates. G. BAUM. U. S. 1,577,201, March 16. The liquid is directly heated by a c., the alternations of which are lower than 500 per sec.

Stabilizing liquid hydrocyanic acid. G. H. BUCHANAN. U. S. 1,577,057, March 16. A small proportion of CNCl or other halogen compd. is added.

Nitrogen peroxide. Soc. D'ETUDES MINIERES & INDUSTRIELLES. Brit. 237,762, Sept. 18, 1924. In prepg. NO₂ by interaction of NH₃ and O in the presence of rhodium black as described in Brit. 133,041 (C. A. 14, 325), the O is replaced by air or oxygenated air and the rate at which the mixt. is passed over the catalyst is slower than that when O alone is used.

Ammonia from gases containing hydrogen cyanide. B. F. HALVORSEN. U. S. 1,580,038, April 6. A gas mixt. contg. H and HCN is mixed with O and the mixt. is passed at an elevated temp. over a suitable catalyst to produce NH₃. A temp. of about 400° may be employed when Fe and Cr oxides are used as catalyst.

Ammonia synthesis. G. CLAUDE. U. S. 1,579,647, April 6. In direct NH₃ synthesis, H and N are caused to react within a chamber and the heat generated by the reaction is eliminated while the metallic pressure-resisting wall is maintained at a uniform temp. The entering gases surround the reaction chamber contg. the catalyst. Cf. C. A. 19, 2729.

Zinc oxide. W. T. GIDDEN and W. G. RAGG. U. S. 1,579,302, April 6. See Brit. 228,244 (C. A. 19, 2866).

Sodium chloride from saline liquors. A. W. GAUGER and H. H. STORCH. U. S. 1,576,739, March 16. Saline liquors such as alkali lake brines are evapd. so that NaCl and other salts are crystd. out, the crystals are sepd. from the concd. liquor, ground to finely divided form and washed with original liquor.

Purifying sea salt, etc., in stages by washing with water or brine. NAAMLOOZE VENNOOTSCHAP MATECHU MAATSCHAPPIJ TOT EXPLOITATIE VAN CHEMISCHE UITVINDINGEN. Brit. 237,867, Aug. 2, 1924. Mech. features.

Aluminum chloride. A. M. McAFEE. U. S. 1,578,052, March 23. A mixt. comprising C and oxidized Al compds. such as bauxite is treated with Cl and the period of induction in the production of AlCl₃ is shortened by first contacting with the solid

materials a mixt. of Cl and returned gases from AlCl_3 condensers or other gas contg. an oxide of C and then continuing the operation with a gas contg. a greater proportion of Cl. Cf. C. A. 19, 2730.

Rochelle salt crystals. A. M. NICOLSON. U. S. 1,578,677, March 30. In prepg. a mother liquor from which to grow hour-glass crystals of Rochelle salt, the salt is dissolved in H_2O to secure complete equil. between the solvent and the solute, the soln. is maintained at all times at a temp. not exceeding 40° and at a d. of 1.37-1.38 ($38^\circ/50^\circ$).

Alkali metal sulfides. G. DE BETHUNE and R. VAHRENKAMPF. U. S. 1,578,718, March 30. An atm. of H_2S from an external source is used for effecting double decompn. of compds. of alkali metals such as NaNO_3 and of Ba sulfide to form a sulfhydrate.

Insoluble alkaline earth arsenates. D. LOPEZ. U. S. 1,578,150, March 23. A mixt. of As_2O_3 and $\text{Ca}(\text{OH})_2$ or other alk. earth hydroxide in warm H_2O is treated with Cl. At least 5% of the hydroxide is used in freshly pptd. form. Cf. C. A. 19, 2730.

Hydrogen separation by partial liquefaction of gas mixtures. G. CLAUDE. U. S. 1,579,348, April 6. A heat-exchange system is specified for obtaining H from its mixts. with N, CO and CH_4 . Cf. C. A. 19, 167.

Removing traces of chlorine from air or other gases. L. ROSENSTEIN. U. S. 1,578,850, March 30. The air or other gas to be treated is passed over scrap Fe wet with a soln. of FeCl_2 .

Carbon disulfide. E. LEGELER. Brit. 237,716, July 11, 1924. S is separately evapd. and superheated and led to a reaction chamber in which C is maintained at reaction temp.

Ozone. A. STARKE and H. VON WARTENBERG. U. S. 1,579,162, March 30. Air to be ozonized is passed between electrodes and subjected to a. c. in the form of undamped oscillations of a periodicity of 1000 to 100,000 periods per sec.

Carbon black. O. G. MESSENGER. U. S. 1,577,481, March 23. A gasiform hydrocarbon material such as natural gas is reacted on with a successive series of small regulable portions of O and the residue of C black thus formed is recovered.

Graphite. V. M. WEAVER. U. S. 1,576,883, March 16. Lime is heated with carbonaceous material such as petroleum coke to form a fluid carbide and the heating is continued until the carbonaceous material has been transformed into graphite and the Ca volatilized.

Porous catalytic gels. W. A. PATRICK. U. S. 1,577,186, March 16. Solns. of FeCl_3 or other readily hydrolyzable salts of a heavy metal are mixed with a substance such as a sol. silicate which will react with the acid resulting from hydrolysis of the salt to produce a colloidal soln. that will set to a hydrogel without the removal of the excess acid or salt. U. S. 1,577,187 specifies forming a hydrogel capable of being converted into material having pores of such size that the H_2O content at 30° in equil. with H_2O vapor at substantially 22 mm. of Hg will be at least 21% of its wt. and treating this hydrogel with a dil. soln. of alkali such as NaOH to form a catalytic material. U. S. 1,577,188 specifies a similar catalyst.

Gels for catalytic and adsorbent purposes. W. A. PATRICK. U. S. 1,577,189, March 16. A hard glassy material of substantially the same porous structure as silica gel comprises SiO_2 and oxides of Fe, Cu or other metals. U. S. 1,577,190 specifies making products of this character by mixing solns. of salts of Ni or other metal salts, acid and substances such as silicate solns. which will react with the acid to form a colloidal soln., in such concns. and proportions that neither gelatinization nor pptn. occurs immediately but after some time the entire mixt. hardens into a hydrogel and the latter is then treated to form a hard porous gel.

Resinous cement. L. E. FROST. U. S. 1,576,737, March 16. A cement which has high insulating properties is prepd. by dissolving manila gum or a similar gum resin in H_2O -free C_6H_6 and using this soln. with a solid phenolic condensation product and an inert filler such as SiO_2 .

Molding resinous compositions. C. ELLIS. U. S. 1,579,195, March 30. Resins such as those prepd. by heating tar acids with formaldehyde and MgO and of the type ordinarily hardened by $(\text{CH}_2)_6\text{N}_4$ in the hot press are treated with a regulated proportion of $(\text{CH}_2)_6\text{N}_4$ (usually about 10%) to cause subsequent setting during the molding operation without excessively rapid hardening, so that molded articles of good finish and sharp impressions are obtained.

Articles from phenol-formaldehyde condensation products. W. HUNTER and J. G. FAIRGRIEVE. U. S. 1,579,112, March 30. See Can. 245,651 (C. A. 19, 710).

Phonograph records. V. H. EMERSON. U. S. 1,576,582, March 16. Record tablets are formed of an interior body comprizing silica clay and resin, faced with a thermoplastic sound record material. Cf. C. A. 19, 878.

Waterproofing solution. R. M. MEAKES and G. F. WILLIAMS. U. S. 1,579,725, April 6. A compn. for waterproofing canvas, wood, etc., comprises Irish moss 8 oz., "caustic soap" 6 oz., glue 6 oz., H_2O 1 gal. and linseed oil 1 qt.

Waterproofing composition. C. D. SHAFFER. U. S. 1,579,493, April 6. A compn. for waterproofing leather, canvas or other materials is prepd. by heating and dissolving colophony in gasoline, dilg. and cooling with additional gasoline, and further mixing with a soln. of paraffin in gasoline and with rubber cement.

Material for fireproofing iron, wood, etc. K. SAMSON. Brit. 237,804, Jan. 15, 1925. A compn. for molding or for application in plastic form as a coating material is made by mixing fine wood meal with talc contg. not more than 5% lime, allowing the mixt. to stand for a time, then adding magnesite contg. not more than 2% lime, and moistening with $MgCl_2$ soln.

Synthetic emeralds. J. F. RIERA. U. S. 1,579,033, March 30. A fusion product is formed from a mixt. of SiO_2 , tinted with green or greenish coloring material, with hydrated or anhydrous BeO and with Al_2O_3 and substances such as Li_2CO_3 , H_3BO_3 and Na borate which act as fluxes. The fused mass is subsequently broken into fragments and these are heated to soften them and are molded while softened.

Treating China wood oil. A. G. SCHURICH and G. T. WRIGHT. U. S. 1,577,426, March 16. A product which is suitable for use as a binder with cork, etc., is prepd. by heating China wood oil to form a jelly and then quenching with cold H_2O .

"Composition cork." A. FISCHER. U. S. 1,577,061, March 16. Cork, linseed oil and S are combined with a binder composed of a glue mixt. contg. $(CH_2)_6N_4$.

Clutch facing material. S. SIMPSON. U. S. 1,578,928, March 30. Unwoven asbestos fibers are impregnated with about 10-20% of an asphaltic binder and associated material such as a flux oil and cured to give strength and hardness to the material. U. S. 1,578,929 specifies use of a hardening binder such as linseed oil or other drying oil.

Printer's blanket with a nitrocellulose back and a rubber face. R. JOHN. U. S. 1,578,736, March 30.

Transfer film. C. P. OLSON. U. S. 1,578,203, March 23. A film adapted for hot embossing comprises a ribbon-like strip of "glassine" paper or other flexible material, a layer on this strip consisting of Chinese insect wax and varnish and a coating of metallic powder.

Transfer sheet. C. CAMPBELL. U. S. 1,578,952, March 30. A textile fabric is coated on one side with paper fibers forming an absorbent and adherent coating held only by adherence of the fibers to the fabric. The paper fibers are impregnated with a transfer pigment.

Detergent. C. J. WAGNER. U. S. 1,578,487, March 30. A mixt. for cleaning clothes comprises Na_2CO_3 6, S. 2, turpentine 1 and bluing 1 part.

Detergent paste. A. L. GACOND. U. S. 1,579,698, April 6. A pasty mixt. for cleaning metal ware, etc., comprises H_2O 1 gal., soap 2 lbs., creolin $\frac{1}{2}$ oz. and "household NH_3 " 2 oz.

Mixture for cleaning and polishing metals. B. L. CLUTIER. U. S. 1,579,435, April 6. Hard SiO_2 25, petrolatum 30 and stearic acid 15 parts.

Composition for removing stains. A. E. MOORE. U. S. 1,576,985, March 16. A compn. for removing vegetable juice stains and the like from the hands, etc., comprises citric acid 40-50, pumice stone 40-50 and cuttle-fish bone 5-15% all in powdered form.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Comparative study of laboratory chemical glassware made in France, England, Germany and Austria. P. NICOLARDOT. *Le Verre* 5, 49-53, 73-6, 97-104 (1925).—A résumé of work done in 1916 on Erlenmeyer flasks of 500-cc. capacity. The proportion of CaO is small in the highly resistant glasses, whereas the Al_2O_3 content is apparently high in these glasses. Those contg. the highest and lowest silica mol. ratio are among the most resistant glasses. The most resistant glasses contain B_2O_3 , but the best of them do not contain high B_2O_3 . In all and Al_2O_3 in fair quantities, but the best of them do not contain high B_2O_3 . The glasses cases it seems preferable to replace part of the Na_2O by ZnO or by MgO . The glasses of lowest chem. resistance, some of which contain B_2O_3 , contain no Al_2O_3 ; they are also rich in CaO and K_2O , poor in MgO and contain no ZnO . It would appear that high

CaO glasses are the least resistant and that the K_2O glasses are less resistant than the Na_2O glasses. From the relative proportions of bases and alkalis (to the other constituents) it is not possible to predict the resistance of a glass. LOUIS NAVIAS

Ceramics in the service of industry and economics. FRITZ SPITZER. *Z. angew. Chem.* 36, 287-90(1926). E. H.

The plasticity of clays and kaolins. PFEFFERKORN. *Sprechsaal* 58, 183(1925); *J. Soc. Glass Tech.* (Abstracts) 9, 151; cf. *Sprechsaal* 57, 297(1924); *C. A.* 18, 3692.—In expts. on a series of 5 German clays, P. had found that oxidation of the org. matter at 60–70° by treating finely ground clay with H_2O_2 did not alter the plasticity. No reduction of plasticity followed the extn. of org. matter by using org. solvents to remove org. matter from the clays. Ether extd. 0.2%, acetone-alc. (1:1) 0.2%, CS_2 0.4%, pyridine 2.4%. Further, when the ext. was added to a kaolin there was no appreciable increase in its plasticity. P. tested Keppeler's method of extg. the clay substance by means of dil. HCl. The clay which then passed a 200-sieve after being washed free from acid showed a much greater plasticity. When this more plastic material was wetted up, and poured on to a plaster slab, it set like ordinary clay, but pressure such as squeezing in the hand caused liquid to run away. This was perhaps due to a loosely combined mol. of H_2O and SiO_2 which formed during the action of the HCl. It was not possible to obtain the small particles of free SiO_2 by any method of pulverizing. CO_2 was also useless, and had no effect on Pilsen kaolin even at a temp. of 60–70°, and a pressure of 20 atms., over a period of 1½ months. H. G.

The plasticity of clay. ALEX VON BARANOFF. *Z. tech. Physik* 7, 76-84(1926).—A mathematical paper. B. J. C. VAN DER HOEFEN

Influence of alkalis, acids, and salts upon the plasticity of kaolin. M. JACOBY. *Keram. Rundschau* 32, 634(1924); *J. Soc. Glass Tech.* (Abstracts) 9, 150.—Plasticity numbers of washed Zettlitzer kaolin, Kodauer kaolin treated osmotically, washed Kemnitz and washed Schnaittenbach kaolin, according to Rosenow's formula and app., were detd., with the formula: plasticity no. = (water content × tensile strength) / (load necessary to cause tearing × time load applied) and the tearing tests carried out on cylinders of kaolin 30 mm. in diam. and 25 mm. long. The effect of the addn. of small quantities of various chemicals was measured. Alkalies (in the case measured, NaOH) acted on plastic kaolin in a manner similar to their action on kaolin slips, but in a somewhat diminished measure. Tannin and humic acid raised the plasticity, while raising the colloidal content of the mass. When a certain max. colloidal content was exceeded the effect was the reverse. HCl, AcOH and NaCl lowered the plasticity and the shrinkage on drying and the strength when dry. Analogous results were obtained for measurements on plasticity, drying shrinkage and dry strength, and it was thought that the latter 2 might give a measure of the former. It was also claimed that OH ions and colloids raised the plasticity to a certain limit, and H ions continuously lowered it. The plasticity numbers for the NaOH expt. were:

NaOH added %	Washed Zettlitzer	Osmosed Kodauer	Washed Kemnitz	Washed Schnaittenbach
0	141	111	102	55
0.1	169	119	117	58
0.2	188	142	145	62
0.3	54	101	78	85
0.4	72	124	64	102
0.5	52	147	61	124
0.6	86	203	145	54
0.7	194	211	173	70
0.8	135	103	149	106
0.9	112	110	134	98
1.0	82	120	166	79

H. G.

Production methods, especially froth flotation processes and electroosmotic purification of clay and kaolin. KUNO WOLF. *Metall u. Erz* 22, 474-80(1925).—A discussion of purification processes based upon differences in sp. gr., magnetic properties in the dry and liquid states, and oil flotation. C. G. KING

Some properties of clay-sillimanite mixtures. J. W. COBB AND H. S. HOULDSWORTH. *British Clayworker* 33, 274-6(1924); *J. Inst. Metals* 33, 564.—The effect of the addn. of sillimanite in varying proportions to Farnley fireclay on the drying and firing shrinkages, porosity, true and apparent sp. gr., refractoriness, reversible thermal expansion, and resistance to attack by Na_2O -CaO glass and by basic slag is investigated.

The presence of 50% of sillimanite or more leads to a pronounced increase in refractoriness; but though a mixt. contg. 90% sillimanite is very resistant to attack by glass and slag, mixts. contg. less than 70% do not seem to offer any advantage over fireclay alone in this respect.

Alleged sillimanite in ceramic products. W. EITEL, *Keram. Rundschau* **33**, 470(1924); *J. Soc. Glass Tech.* (Abstracts) **9**, 151.—E. discussed the methods and results obtained by Shepherd, Rankin and Wright (*C. A.* **5**, 1982) and by Bowen and Greig in their studies of the system $Al_2O_3-SiO_2$. In 1914 E. had produced an artificial agreeing more nearly with that of mullite. About 1% of $Fe_2O_3 + TiO_2$ in solid soln. gave the crystals a higher n . Mullite produced in ceramic products was generally almost Fe-free and so could be identified by its low n . R. G. Wyckoff had shown that natural sillimanite and the compd. $3Al_2O_3 \cdot 2SiO_2$ gave the same diagram when examined by X-rays, so nullifying the claim advanced by Shearer who obtained identical diagrams from sillimanite and porcelain. Sillimanite mixings and natural sillimanite were improved by an excess of Al_2O_3 or natural corundum. Certain insulators made of pure mixts. of Al_2O_3 and SiO_2 must have been burnt at temps. exceeding 1810°, since they contained both corundum and mullite, but a small quantity of foreign oxides considerably reduced the temp. of formation of corundum.

The physical properties of stoneware. FELIX SINGER, *Z. angew. Chem.* **35**, 290-2(1926).—Physical properties of 30 diff. samples of stoneware are tabulated.

Stoneware and chemical industry. A. BINZ, *Z. angew. Chem.* **36**, 285-92(1923).

Correct decolorizing. Dangers of over-decolorizing. L. SPRINGER, *Ceramic Industry* **6**, 522-3(1925).—Glasses low in alk. fluxes are easiest to decolorize. Iron will color in proportion to the amt. of alkali in the batch. The min. amt. of CaO is desirable. K glasses are always brighter and less colored than the corresponding Na glasses. Reducing gases give poor color. In decolorizing glass made from salt cake, the effect of the decolorizers is reduced when they are added directly to the salt cake batch. No attempt is made to decolorize glass in continuous tanks because a large part of the glass remains in the bottom of the glass tank. The best crystal glass can be made only in glass pots. For high-grade white glass, the Fe content of the sand should not be over 0.03%. The Fe content of the calspar should not exceed 0.1% for white glass.

Use of lignite gas in ceramic plants. ADOLPHE FABER, *Chaleur et industrie* **7**, 119-23(1926).—Description of the technique of the use of lignite producer gas for firing ceramic kilns in Germany, with a discussion of its advantages.

The true specific gravity and after-expansion of lime-bonded silica bricks. W. J. REES, *Trans. Ceram. Soc.* **24**, 66-9(1925).—In a study of 10 com. lime-bonded silica bricks it was found that a sufficiently close relation existed for practical purposes between the true sp. gr. and the degree or extent of quartz inversion. For bricks of fine to medium texture there is close relation between the true (powd.) sp. gr. and after-expansion as detd. by standard methods. For practical purposes the grading of the raw material is more important than variations in the source or type of the English raw material. For coarse material ($1/4$ in. and over) expansion and sp. gr. are not closely related owing to the slower inversion rate. After-expansion of from 0.0% to 2.60% was found. The chem. analyses of 40 bricks are given.

The addition of chromium oxide to silica bricks. S. SANDLUND, *Jernkontoretts Annaler* **109**, 358-72(1925); cf. *C. A.* **19**, 566.—Chromium oxide contg. 89.25% Cr_2O_3 was prepd. from $K_2Cr_2O_7$ and C in a lab. furnace. Silica bricks were made with addn. of 0, 2, 3 and 4% of this product, the 4 brick species being called, resp., S, CrS_2 , CrS_3 and CrS_4 . Analyses are given. The following table shows the physical properties of the bricks:

Quality	Temp. of beginning weakness	Sp. gr.	Weight in kg. per l.	Porosity
S	1650°	2.33	1.95	0.16
CrS_2	1615°	2.35	1.89	0.20
CrS_3	1630°	2.36	1.835	0.22
CrS_4	1620°	2.39	1.845	0.25

The resistance to slags was tried in a small elec. arc furnace, 3 types of slag being used, (1) and (2) being acid Martin slags contg., resp., 57.7, 15.91% SiO_2 ; 22.76, 33.37% FeO ; and 13.89, 15.59% MnO besides other minor constituents. (3) was a Bessemer

slag contg. 50.47% SiO_2 , 8.36% FeO , 35.74% MnO , etc. Analyses of the slags after smelting in different linings show that CrS_2 , CrS_3 and CrS_4 were nearly unattacked by all the 3 slags, no advantage being observed with the higher contents of Cr_2O_3 as compared with the 2% type. The S bricks were markedly attacked by slags (1) and (2) but not substantially by (3). The analytic observations were verified by microscopic examns. of the used bricks. C. A. ROBAK

Selecting refractories for use in metallurgical furnaces. E. R. THEWS. *Iron Trade Rev.* 78, 508-9, 638-40 (1926).—The following are the necessary characteristics for metallurgical refractories: high softening and melting temp. under normal load; high resistance against sudden and sharp changes in temp.; chem. inertness; least possible change in shape and vol. under all practical melting conditions; low heat cond.; high mechanical resistance; uniform compn.; ease of dressing brick in laying; accurate and uniform measurements; smooth and sharp-edged surfaces. The grain size of raw materials influences the properties of SiO_2 brick. The lack of resistance against temp. changes in magnesite brick necessitates careful treatment. J. F. B.

Refractories for high temperatures, especially for electric furnaces. D. W. BERLIN AND J. HARDÉN. *Jernkontorets Annaler* 1922, 186-7; *J. Inst. Metals* 33, 558. —A mixt. of fused magnesite crushed to 0.5 mm 75, Cr ore crushed to 0.5 mm. 20, magnesia alba 5% has proved to be an excellent refractory, especially in elec. furnaces used for the melting of metals. This refractory does not bring any C or other foreign matters into the bath. Definite conclusions cannot as yet be drawn as to its shrinkage and freedom from cracking on cooling. H. G.

Abrasives: their use in finishing of metals. W. S. BARROWS. *Can. Foundryman* 15, 26 (1924); *J. Inst. Metals* 33, 525. —The importance of running, polishing and grinding wheels at the correct speed is emphasized. Generally, a min. speed of 4000 surface ft. per minute is correct, but hard tough abrasives can be used at higher speeds than softer ones, because the latter quickly crush and glaze. SiC is not merely a grinding abrasive, but, in the finer grades, can be used for polishing. Corundum is superior to emery in that it does not cause the article that is being ground to rise in temp. so much as when emery is used. H. G.

Coagulation of clay (GALLAY) 2. Silicate analysis (SCHWARZ, SCHINZINGER) 7. Structure of kaolin (DOMINIKIEWICZ) 8.

SPRINGER, LUDWIG: *Die Fortschritte des Glastechnik in den letzten Jahrzehnten.* Braunschweig: F. Viewig & Sohn. 52 pp. R. M. 2 50.

Glass furnace. G. E. HENNING. U. S. 1,579,364, April 6. A bridgeless tank has an individual bridge wall in the flow spout.

Glass furnace with water-cooled bridge. R. GOOD. U. S. 1,579,353, April 6

Refining glass. W. O. AMSLER. U. S. 1,577,602, March 23. Mech. features

Leer for annealing sheet glass. W. G. KOUPAL. U. S. 1,576,516, March 16

Cutting plastic quartz. L. B. MILLER. U. S. 1,579,019, March 30. Mech. features

Ceramic material ("synthetic clay"). R. T. STULL. U. S. 1,576,558, March 16

A material for making light colored brick comprises a mixt. of natural highly colloidal secondary kaolin deficient in alkali and alk. earth fluxes, with a pegmatite.

Continuously operated kiln for burning and drying brick, etc. C. SMITH. U. S. 1,578,559, March 30

Face brick. S. M. DUTY. U. S. 1,578,409, March 30. Finely divided material such as ground shale is applied to the surface of wet molded bricks and subsequently burned into the surface.

Vitrified insulators. F. RICHARD. U. S. 1,579,032, March 30. A natural clay contg. about 56% SiO_2 , 20% Al_2O_3 , 8% Fe oxide, and alkalis is mixed with sufficient H_2O to form a plastic mass, molded, heated to about 480° and then further heated to a temp. not exceeding about 870° to effect vitrification.

Refractory material. O. H. ESCHHOLZ and P. G. GUEST. U. S. 1,576,732, March 16. "Arc splitters" or similar articles comprise a refractory base including SiO_2 and Na silicate in hydrous form as a binder, with a thin surface glaze of anhydrous Na silicate.

Refractory cement. W. F. ROCHOW. U. S. 1,576,550, March 16. A dry powdered cement compn. adapted for use in furnace walls comprises silica, fireclay, calcined silica and 5-20% of Na silicate.

Refractory chemical-resisting articles. S. J. LUBOWSKY. U. S. 1,578,900, March

30. Filter plates or cups or other articles are formed of crushed rutile, the particles of which are bound together to form a porous body by use of a temporary heat-destructible binder, which is destroyed in sintering the rutile particles together. Cf. C. A. 20, 650.

Refractory articles. A. J. JACKMAN. U. S. 1,577,124, March 16. Crucibles, saggars or other refractory articles are formed principally of graphite and a vitrifiable ceramic bond, burned prior to use at a temp. above the vitrification of the bonding material.

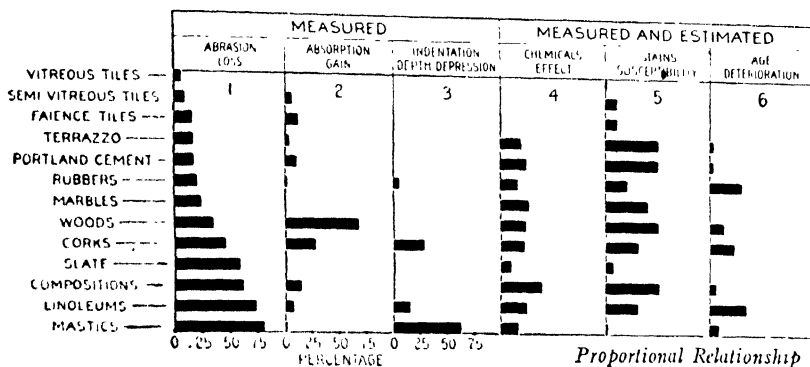

Enameling metal. W. J. BECK and J. A. ATTERLEE. U. S. 1,578,706, March 30. Metal for enameling is formed of open-hearth or similar mgot Fe refined to a stage where the Mn content is below 0.04% and degasification has taken place to the extent of leaving a substantially sound metal and not to the extent of removing all the oxide content, so that well-distributed spots of oxide are visible under the microscope in the surface and through the body of the metal.

Enameling the interior of pipes. W. LAMBERT and A. A. MILAD. U. S. 1,571,531, March 23. A hot pipe is rotated about a nozzle which is passed within the pipe to supply reducing gas and enamel.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Endurance of flooring materials. C. H. GEISTER. *J. Am. Ceram. Soc.* 9, 126-30 (1926).—The data are summarized in the following chart

C. H. KERR

A refractory hydraulic cement. J. ARNOULD. *Chimie et industrie* 15, 181-8 (1926). A mixt. of fused cement ("electric" or "aluminous" cement), MgO calcined at 1000° and water glass gives a good cement which stands up at fairly high temps., but which unfortunately sets too rapidly. A 1-2 mixt. of fused cement and of calcined (above 1070°) and ground bauxite constitutes a true hydraulic cement, which, on mixing with 22-30% H₂O, begins to set in 1 hr. and is completely set in 1-6 hrs. It hardens very rapidly, and after 3 days has a crushing strength of 115 kg. per cm.² and a tensile strength of 21 kg. per cm.². It can be made into concrete by using 1, 2 or 3 parts of broken up old refractory bricks (screened, or preferably washed, to remove dust) to 3 parts of cement, which is used and handled the same as ordinary portland cement concrete. Both the cement (fused cement bauxite mixt.) and the concrete after setting soften at 1350-1400° and m. at about 1600°. The cement has a crushing strength of 20 kg. up to 1200-50°, which drops to 2 kg. at 1300-50°, above this it becomes quite soft, but does not flow. The crushing strength curve at high temps. lies between the corresponding curves of bauxite and of carbundum. Both the cement and the concrete have a very small shrinkage, 1-1.5% at 1350°, and as low as 0.5% in some cases. They are remarkably resistant to sudden changes in temps. and do not crack on rapid cooling from 1380° to 20°. Strength tests on the cold cement after heating to various temps. showed a certain degree of friability (probably due to elimination of H₂O of constitution), which appeared at about 800° reached a max. at 1000°.

1200°, and disappeared at about 1300°. The friability decreases with the proportion of bauxite in the mixt. Friability in the concrete can be completely eliminated by heating once above 1250°. The addn. of broken refractory in the concrete decreases the shrinkage, increases the strength, prevents cracking of the concrete, and cheapens the product, but increases the friability. BeO gives the same results as Al_2O_3 , which confirms the place assigned to it in the table of elements, but is of no practical interest. Presence of up to 3% TiO_2 in the bauxite causes no trouble. Using an aluminous cement prepd. by clinkering instead of fusion raises the m. p. of the cement-bauxite mixt. by about 50°. The friability can be reduced, and even eliminated completely, by addn. of a little powdered flint or powdered Na silicate (of low alkyl. and consequently non-hygroscopic); but this lowers the m. and softening points. A. PAPINEAU-COUTURE

Reactions occurring during the burning of synthetic cement mixtures. W. DYCKERHOFF. *Zement* 14, 174-7(1925).—Mixts. consisting of 66% CaO, 24% SiO_2 and 10% Al_2O_3 are held for 20 min. at temps. up to 1500°, the products formed being examd. microscopically to det. the constituents of normal portland cement clinker. In following the heating curve of the batch there is a lag of about 200° around 910° during the expulsion of the CO_2 . At 1000° $\text{CaO} \cdot \text{SiO}_2$ forms and from 1100° to 1360° α -, β -, and γ -dicalcium silicate are formed, the loosely adhering powder being composed largely of γ - $2\text{CaO} \cdot \text{SiO}_2$ at the higher temp. No calcium aluminates appear to form below 1360°. At 1390° an exothermic reaction takes place which is the m. p. of the eutectic $5\text{CaO} \cdot 3\text{SiO}_2$ and $2\text{CaO} \cdot \text{SiO}_2$. On cooling, recrystn. of the constituents causes a break in the curve near 1350°. On quickly cooling a melt at temps. above 1390° $2\text{CaO} \cdot \text{SiO}_2$ crystals are found in a matrix of $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$. On slow cooling after being raised to 1500° these crystals were found— $2\text{CaO} \cdot \text{SiO}_2$ chiefly of the β -form with some of the γ - but no α -forms, isotropic crystals of index 1.710 which were taken to be $3\text{CaO} \cdot \text{Al}_2\text{O}_3$, others of index 1.608 assumed to be the stable form of $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$, and very few crystals of index 1.74 or CaO. No $8\text{CaO} \cdot 2\text{SiO}_2$, Al_2O_3 , $3\text{CaO} \cdot \text{SiO}_2$ or $\text{CaO} \cdot \text{SiO}_2$ were found, there being not enough time for the 2 former compds. to form. D. states that this reason prevents $3\text{CaO} \cdot \text{SiO}_2$ being formed in com. cement. The β - to γ -inversion of the $2\text{CaO} \cdot \text{SiO}_2$ throws out of solid soln. the CaO held and it can be seen as tiny crystals in with the γ -form. When the inversion had been carried to completion by long heating at 1450° there was found to be practically no set to the ground clinker even after 8 days. On quick cooling of a mix held at this temp. for 20 min. the set produced was equal to that of normal portland cement. From this it is concluded that the set is due chiefly to the β - $2\text{CaO} \cdot \text{SiO}_2$, this with the CaO dissolved being nearly $\frac{2}{3}$ of the whole. With SiO_2 -rich and Al_2O_3 -rich mixes the minerals produced were identical with those of a normal cement. To retain the dissolved CaO in the β - $2\text{CaO} \cdot \text{SiO}_2$ quick cooling of the sintered mass must occur. The effect of this constituent on the hardening of cement is compared to that of Fe_2C in steel. Portland cement clinker may then be considered an undercooled soln. of CaO in $2\text{CaO} \cdot \text{SiO}_2$. H. F. K.

The petrography of modern portland cement clinkers. CARL BIEHL. *Zement* 14, 379-82, 397-9(1925).—The compn. temp. of burning, and rate of cooling are factors affecting the quality of cement. These can be successfully studied by microscopic mineralogical methods since the kind and degree of crystn. are governed by these conditions, plus the influence of fluxes. The so-called alite is considered to be $2\text{CaO} \cdot \text{SiO}_2$ while belite and celite seem to be members of an isomorphous series whose chief variable constituent is Fe_2O_3 . Well-crystd. clinker results either from high temps. and the presence of fluxes or from quick cooling which prevents the complete crystn. of the minerals and retains in the mass latent energy which is liberated during the setting of the cement. Fifteen photomicrographs are included and discussed. H. F. K.

The hydration of aluminates rich in lime. KRISTO RADEFF. *Zement* 14, 177-82 (1925).—Melts varying in compn. from $\text{CaO} \cdot \text{Al}_2\text{O}_3$ to $4\text{CaO} \cdot \text{Al}_2\text{O}_3$ were prepd. from pure materials. Finely powd. samples were kept in an excess of satd. $\text{Ca}(\text{OH})_2$ soln. in sealed containers at 20° for 1-16 days under const. agitation. After filtering through a membrane in the absence of CO_2 an aliquot of the filtrate was run for CaO and Al_2O_3 . The compn. of the residue was calcd. from these data. The detns. were continued on sep. samples until no change was found in the compn. of the filtrate and equil. had been established. $\text{Ca}(\text{OH})_2$ was found to react with any kind of $\text{Al}(\text{OH})_3$, if shaken with it, but only freshly pptd. $\text{Al}(\text{OH})_3$ reacted quickly. Tricalcium hydroaluminate results from the hydration of $3\text{CaO} \cdot \text{Al}_2\text{O}_3$, it being also the end product of the hydration of $\text{CaO} \cdot \text{Al}_2\text{O}_3$ and $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ in the presence of sufficient CaO. The melt of the compn. of $4\text{CaO} \cdot \text{Al}_2\text{O}_3$ lost CaO during hydration and its existence as a tetracalcium hydroaluminate is doubtful. The crystd. aluminate formed from $\text{Ca}(\text{OH})_2$ and $\text{Al}(\text{OH})_3$ approaches the compn. $1\text{CaO} \cdot 3\text{Al}_2\text{O}_3$. Amorphous masses of $\text{Al}(\text{OH})_3$ and $\text{Ca}(\text{OH})_2$

cannot exist together in set cement. Either of these can appear in an amorphous form only when the other constituent is deficient.

Absorption of moisture by portland cement during storage. V. BODT *Zement* **14**, 520-2(1925); *Chimie et industrie* **15**, 242(1926).—When the atm. relative humidity is 10-50% the absorbed H_2O reaches a max. of not over 1% in 25 days or less. With a relative humidity of 60% a max. absorption of about 2% H_2O is reached in 25 days. With higher humidities, the following absorption took place: at 70%, absorption of 5.8% in 143 days; at 80%, 18.2% in 189 days; at 90%, 22.0% in 85 days. When large masses of cement are stored absorption takes place only in the outside layer in contact with the atm.

Chemico-technical studies in bituminous road making. A. PAPINEAU COUTURE *Teer* **24**, 139-41(1926).—A brief explanatory discussion of pitch specifications.

W. B. PLUMMER

Steam treatment in kilns for preserving resinous lumber (U. S. pat. 1,577,014) **22**.
Cement from iron ores (Brit. pat. 237,779) **9**.

HARRIS, W. R.: Concrete Products, Their Manufacture and Use. Chicago: International Trade Press. 640 pp. Reviewed in *J. Western Society of Engineers* **31**, No. 1, 9(1926).

Coloring cement or other building materials. J. KOEBIG U. S. 1,577,729, March 23. The material is treated with a soln. of substances which react after being applied to form a H_2O -insol. coloring material, e. g., lake- or pigment-forming substances.

Plaster opaque to X-rays. P. E. HARTH U. S. 1,576,730, March 16. A wall covering is formed of a cemented mixt. of sand and a powder such as $BaSO_4$, both of which are opaque to X-rays, the proportion of the powder increasing toward the surface of the wall.

Slaking lime. C. E. HITE U. S. 1,579,766, April 6. Quicklime is slaked with a lime-S soln. to produce a plaster or mortar material of good strength.

Composition for mortar, etc. C. E. HITE U. S. 1,579,611, April 6. Hydrated lime is made into a plastic mass with a lime-S soln.

Cement mortar. W. KIRCHNER U. S. 1,578,139, March 23. Cement mortar is stirred with H_2O contg. protalbinic and lysalbinic acids, in order to increase the strength and impermeability of the product.

Building blocks. C. A. PERKINS and H. A. PERKINS U. S. 1,578,091, March 23. Blocks simulating natural stone have a facing of mixed granite dust, ground mica, black slag and white cement.

Paving and building blocks. G. B. STRYKER and F. A. MANTEL U. S. 1,578,481, March 30. Ground cotton stalks or other vegetable fiber 70-80, ashes 10-20 and a bituminous binder 10-20% are used together.

Ornamenting artificial stone. A. N. P. JACOBS U. S. 1,577,972, March 23. The material is impregnated with an insol. compd. of a heavy metal, e. g., with Pb oxide or white lead, and then imprinted and coated with a gum, e. g., dextrin, and with a soln. of H_2S .

Coating floors. J. F. NACHOD U. S. 1,579,729, April 6. A thin soln. of bitumen is applied to a floor as a priming coating, permitted to dry, and a thick soln. of bitumen is then applied. Coloring and stiffening materials may be admixed with the superficial coating.

Road composition from rock asphalt. W. P. BENTLEY U. S. reissue 16,301, March 30. See original pat. 1,529,829, C. A. **19**, 1625.

21 FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Analyses of Missouri coals. Mine samples. A. C. FIELDNER, H. M. COOPER AND F. D. OSGOOD *Bur. of Mines, Tech. Paper No. 366*, 8-33(1926) Delivered coal. N. H. SNYDER *Ibid.* **31**, 7.

Composition of durain. N. SIMPKIN. *J. Soc. Chem. Ind.* **45**, 76 ST(1926)—See C. A. **20**, 1312.

Coal in South Africa. W. M. T. HESLOP. *J. Chem. Soc. S. Afr.* **25**, 157-72 (1925).—Testing is very frequent in S. African collieries because of variation in quality.

Analyses are given of the coal mined from various areas and districts, as well as analyses of coal ash from the Natal district. H. also discusses mining conditions. H. C. P.

The investigation of coal and determination of its suitability for commercial low-temperature distillation. ERNST LÁSZLÓ. *Chem.-Ztg.* 50, 173-5(1926).—The ordinary coal analysis is not suitable for use in judging the value of coal for low-temp. distn., although it may be of value in high-temp. work. In high-temp. distn. the first step really gives low-temp. products, but these are subsequently changed into high-temp. products before they can escape from the retort. To get an adequate idea of the value of coal for low-temp. work the use of large pieces (not powder) in the sample, of a large sample, of an iron retort shaped like an inverted Erlenmeyer flask or an egg, and occasionally of means for heating in inert gas, are recommended, and a number of analytical procedures are outlined. W. C. EBAUGH

Operation and economics of powdered-coal firing. SCHULTZ. *Feuerungstechnik* 13, 111-2(1925).—Remarks on the performance of some German installations.

Determination of temperature of plasticity of coals. C. F. FOXWELL. *Ind. Eng. Chem.* 17, 1161(1926).—A critic of the work of Layng and Hathorne (C. A. 19, 884). W. C. EBAUGH

The fusibility of coal ash. A. C. FIELDNER AND W. A. SELVIG. *Fuel in Science & Practice* 5, 24-33(1926).—A review and discussion of work by the U. S. Bur. of Mines. Eleven references relating to the subject are included. C. C. DAVIS

Compressed metaldehyde or white coal. P. BRUÈRE. *Ann. f.uls.* 19, 70-3(1926).—Stabilization according to Fr. pat. 547,152, of Sept. 13, 1922 (Usines Electriques de la Lonza), consisting in elimination of paraldehyde by means of vacuum at 20-5° and neutralization of the catalyst by aq. Ba(OH)₂, Ag salts or colloidal substances, is very efficient: untreated metaldehyde (I) lost over 50% of its wt. in less than 2 hrs. and gave a positive test for sulfates, while the stabilized product showed practically no change in wt. in 1 yr. The fuel value of n g. of I is practically equiv. to that of 100 cc. of n% denatured alc. I burns with a slight odor of AcH and leaves no appreciable residue, while trioxymethylene leaves a slight yellowish gray residue and burns with an odor of CH₂O. According to Denigès (C. A. 20, 1043) I gives a blood-red color with guaiacol and H₂SO₄; under the same conditions trioxymethylene gives an intense violet, sucrose gives as strong a color as I, and lactose and starch give a rose color. A. PAPINEAU COUTURE

The determination of carbon in coal. J. G. KING AND D. MACDOUGALL. *Fuel in Science & Practice* 5, 33-5(1926).—Expts. were carried out to det. the best temp. and time of contact with CuO of the gases from the ordinary combustion method. The conditions used were those of the Sampling and Analysis Coal Committee of the Fuel Research Board (Phys. and Chem. Survey of the National Coal Resources, No. 2 *Interim Report on Methods of Analysis of Coal*) and a bituminous coal high in volatile with strong tendency to cake was chosen as that offering the greatest difficulty in detg. C. This method was found to be entirely satisfactory if 30 min. are allowed for heating the coal to 800°, if a temp. of 800° is maintained 50 min. to complete combustion and if the O is swept out with air for 30 min. The CuO layer need not be over 45 cm. long, but a min. length of 20 cm. in the center section should be maintained at 800°. Under these conditions, even with rapid heating, the loss of C is not over 0.015%. Below 800°, the amt. of C escaping is greater. At 700° and 650° results accurate to 0.3% can be obtained by careful manipulation, but there is a tendency for variations over 1% to occur. C. C. DAVIS

The microscopic structure of mineral coal. ANDRÉ DUPARQUE. *Compt. rend.* 182, 475-7(1926).—The examn. of different types of coal by the metallographic method indicated that they are composed of 2 microscopic components: (1) *substances of definite pattern and of vegetable origin* (lignified tissue, spores, algae, etc.) and (2) a *colloidal structureless paste or matrix*, the "fundamental substance" of secondary origin, i. e., subsequent to component (1). The 4 macroscopic components (fusain, durain, clarain and vitrain) are derived from the association or the sepn. of the first or second component. The fundamental substance, which was identified as vitrain, originated in 2 different ways: (1) by jellying of the substances of definite figure, evidence of which was seen in transition stages of the ligneous masses and spores to vitrain and in lenses of clarain or of vitrain in durain and (2) by pptn. of org. substances from water, the original substance having undergone total destruction. This latter process accounts for the fine bands of vitrain and of paste-like masses of clarain and of durain in bright coal. Animal organisms, complete or fragmentary, were not observed in vitrain and the 2 microscopic components of coal appear to be almost exclusively vegetable in

origin. Furthermore the volatile content of coals is inversely proportional to the development of the fundamental matrix. Bogheads, cannel-coals, bright coals and durain show different proportions of the fundamental matrix and different proportions and states of development of the spores, algae, etc., evidence indicating that the 3 types of coal are of different origin.

The initial decomposition of coal by heat. M. J. BURGESS AND R. V. WHEELER. *Fuel in Science & Practice* 5, 65-8 (1926) - Thermal decompn. *in vacuo* of Lancashire Silkstone coal already described (C. A. 8, 1865), the same app. and the same technic being used. The gases removed *in vacuo* up to 200° were chiefly paraffin hydrocarbons and appeared to be occluded, but the character of the gases evolved between 270° and 300° indicated that they were decompn. products of the coal substance. Simultaneously with the appearance of these gaseous decompn. products which were chiefly CO and CO₂, traces of a reddish brown oil were distd. at about 280°. This latter temp. was considered as the initial temp. of decompn. of the particular Lancashire coking coal, which was essentially clarain.

Recent developments in fuel technology. R. WIGGINTON. *Fuel in Science & Practice* 5, 1-5, 45-7, 89-91 (1926); cf. C. A. 20, 101 - Short reviews in abstract form.

Powdered fuel. W. LULOFS. *Combustion* 14, 40-3 (1926) - A system of burning powdered fuel in conjunction with mechanical stokers is described. This combination is effected by inserting a number of small burners of powdered fuel at the rear of the stoker in such a manner that a row of small flames from these burners is directed almost parallel to the mechanical grate but pointing slightly toward it. This results in increased efficiency due to better contact of the excess air with the combustible material and utilization of the excess air for completing the combustion of the powdered fuel, increased evapn. due to higher temp. in the combustion chamber, and increased adaptability for a varying load due to instantaneous adjustment by regulating the supply of powdered fuel. A general discussion of powdered fuel and of the central vs. the unit system is given.

Fuels for high-compression engines. S. W. SPARROW. *Oil & Gas J.* 34, No. 34, 118, 120, 122, 181-90 (1926) - Contains a bibliography. Preignition and detonation are the most important phenomena of a motor fuel. Calorific value, explosive range, distn. range, latent heat of evapn., l. p., viscosity, corrosiveness, sp. gr., chemical compn. and rate of flame propagation are the important properties affecting the value of a fuel. Ethyl alc. is adapted for use with higher-compression ratios than gasoline. Kerosene is rendered anti-detonating by the addition of xylidene with the absence of alc. Data are given.

Ash from powdered fuel installations. J. T. DIXON. *J. Soc. Chem. Ind.* 45, 60-1T (1926).—Size analyses are given for various samples which settled out at points within various plants (in stack flues, Cottrell precipitator, etc.), for 3 such samples from 3 American plants, size data are 48-58% < 0.01 mm. diam., 18-22% 0.01-0.02 mm., 11-16% 0.02-0.03 mm., 10-12% 0.03-0.06 mm., 1-4 3.2%, 0.06-0.1 mm., 0.1-0.5% 0.1 mm. Significant samples of material, which have been carried out of the stack and deposited, cannot be readily obtained.

Fuel briquets in 1924. W. F. MCKENNEY. *Bur. Mines, Mineral Resources of U. S.*, 1924, Part II, 187-92 (preprint No. 17, published Mar. 20, 1926).

The estimation of unburned carbon from the analysis of flue gases. W. R. CHAPMAN. *Fuel in Science & Practice* 5, 128-9 (1926) - The idea that a flue gas analysis cannot yield information on the quantity of unconsumed C lost during combustion on an industrial scale, as maintained by Kreisinger (C. A. 20, 274) and others, is fallacious. The loss of C can be calcd. from the compn. of the original coal, to which end the following formula is derived: $\text{unburned C} = 100 + 37.5\alpha - [1.5\alpha(1 + s + r) + (1140\beta + 42.8\delta - 142.5\gamma)] / [100 - 4.8r - 2.9s - 1.8t + 0.9u + 2.8v]$, where α is the % C, β the % H, γ the % O, δ the % N and ϵ the % S in the ash free, dry coal and r is the % CO₂, s the % CO, t the % O₂, u the % H₂ and v the % CH₄ in the flue gas. This formula is especially useful in the control of pulverized fuel, where large quantities of unconsumed coke particles may pass into the flue gases even when a large excess of air is used. In some cases a CO recorder would indicate a good combustion efficiency and a flue gas analysis also would indicate a better efficiency than that revealed by calcg. the unburned C according to the formula above. The latter is applicable to boilers and furnaces fired either by mech. stokers or by hand.

Flue gas injury of plants from the standpoint of metabolic pathology. KURT NOACK. *Z. angew. Chem.* 39, 302-1 (1926) - The real cause of the highly poisonous

action of H_2SO_4 for illuminated green plants is due to the fact that it stops C assimilation. Then the photo-oxidative energy of chlorophyll which normally finds an acceptor in the CO_2 lacks this acceptor and the protoplasm becomes the acceptor resulting in the death of the cell. SO_2 is hence only an intermediate agent in the killing.

H. R. KRAYBILL

Development tendencies of the German fuel economy. M. DOLCH. *Z. Elektrochem.* 32, 63-7 (1926).—The surplus coal, not necessary for direct energy production, will have to be considered as raw material for the manuf. of liquid fuel or products other than fuels; the energy market at the present time is overloaded. Processes important in this respect are: (1) low temp. carbonization with the object maximal tar production and (2) liquefaction of the coal (Bergius or B. A. S. process); the latter procedure promises best for the future.

B. J. C. VAN DER HOEVEN

Combustion control in explosion engines by analysis of the exhaust gases and by the use of combustion diagrams. BERNARD JOUSSET. *Chaleur et industrie* 7, 124-6 (1926).—A theoretical mathematical discussion of combustion of hydrocarbons with deficiency, excess and theoretical amt. of air, showing how the ratio of air to gasoline can be found from the CO_2 content of the exhaust gas, and indicating the manner of using the results in regulating the operation of explosion engines.

A. P.-C.

Adiabatic ignition of mixtures of hydrocarbons. ANDRE PIGNOT. *Compt. rend.* 182, 376-7 (1926).—The initial temp. necessary to ignite mixts. of air with $n\text{-C}_4\text{H}_{10}$, $n\text{-C}_5\text{H}_{12}$, $n\text{-C}_6\text{H}_{14}$, cyclohexane, PhH, PhMe, $m\text{-C}_6\text{H}_4\text{Me}_2$, 1,3,5- $\text{C}_6\text{H}_3\text{Me}_3$ and EtOH on a sudden fixed compression was measured. The method is proposed as of general value in testing fuels. Curves obtained are said to differ for aliphatic and aromatic compounds, to be affected by traces of more combustible materials and by concn. NH_3 , PhMe and CS_2 are without great effect. No data or curves are given in the article.

M. B. HART

Elimination of sulfur impurities from technical cresols and petroleum. G. I. STADNIKOV, N. M. GAVRILOV AND V. E. RAKOVSKII. *J. Chem. Ind.* (Moscow) 2, 315-9 (1925).—To eliminate the acidic S compds. the authors propose to use the reaction of condensation with aldehydes on the principle that the speed of condensation of thiocresols with aldehydes is much greater than that of cresols. The aldehydes used were a glucose soln. and a 40% aq. soln. of CH_2O . It is very important to maintain during the reaction an intimate contact between the aldehyde and the oil. As a condensing agent petroleum sulfonic acids (condensing agent of G. S. Petrov) were used as they have the advantage over H_2SO_4 of emulsifying the oil with the aq. solns. of the aldehydes. The sulfonic acids and the glucose soln. are mixed with an equal quantity of the oil and the mixt. is introduced in small portions into the bulk of the oil contained in a distg. flask provided with a stirrer and a condenser and immersed in an oil bath at 120° . Under these conditions the water introduced together with glucose or with formaldehyde is gradually distd. off and does not settle to the bottom. Then the oil is distd. off *in vacuo*, the temp. of the bath being not over 140° . Crude coal-tar cresol with a S content of 2.24% gave by the treatment with 1% sulfonic acids and glucose soln. to the amount of 3% a product contg. but 0.01% S and not darkening on keeping for several months. The presence of neutral oils in large quantities interferes with the removal of S substances of acid character, as the neutral oils do not emulsify with aldehyde solns and do not condense with aldehydes. As a rule, when cresols contain more than 10-15% of neutral oils S is not removable by this method.

BERNARD NELSON

Investigations on low-temperature carbonization at the Sarre mines. J. SAINTE CLAIRE DEVILLE. *Chimie et industrie* 15, 163-71 (1926); cf. *C. A.* 20, 101, 490.—The app. used for the investigations, consisting of a small Salerni retort having a capacity of about 100 kg. per half-day, and of a small exptl. distn. plant with two 15-ton per day Salerni retorts, is described in detail, and the general procedure of the tests on the various types of raw materials outlined. The economic feasibility of low-temp. carbonization is discussed, and D. concludes it is practical provided the raw material is of

Crude coal gas for recovering scrap copper and brass. CH. BERTHELOT. *Le gaz; Gas World* 83, 96(1925).—The wastefulness of melting scrap Cu and brass, the loss of Zn and heavy transport charges for electrolysis are pointed out. It is more economical to sell Cu and Zn as cryst. sulfates. CuSO_4 and ZnSO_4 cannot be sepd. by crystn. The Cu or brass is dissolved in H_2SO_4 and crude coal gas is passed through the soln. CuS is deposited and H_2SO_4 regenerated. $\text{CuSO}_4 + \text{H}_2\text{S} = \text{CuS} + \text{H}_2\text{SO}_4$. On exposure to air or an oxidizing agent CuS becomes CuSO_4 . $\text{CuS} + 2\text{O}_2 = \text{CuSO}_4$, which is washed out and crystd. The liquor contains ZnSO_4 and H_2SO_4 and is used again and the Zn crystallized out occasionally. A production of $3\frac{1}{2}$ million cu. ft. of gas per day would give 10 cwt. of S as H_2S which would ppt. 0.984 ton Cu and yield 3.889 tons $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. If brass contd. $\frac{1}{3}$ Cu and $\frac{1}{3}$ Zn, $1\frac{1}{2}$ tons brass could be handled per day, yielding 2.808 tons $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$. Costs are given in terms of francs.

Resistance to the flow of gases in the fuel bed of a coke-fed furnace or a water-gas generator. M. W. TRAVERS. *J. Soc. Chem. Ind.* 45, 61–3T(1926).—Brief discussion and calcs. based on the data of the Bur. Mines, *Tech. Paper* 137 (C. A. 11, 1740) for blast volume versus blast pressure in a small furnace. Complex equations are presented relating certain of the variable and const. factors, and choking in the reaction zone is discussed.

W. B. PLUMMER

The corrosion and rusting of wrought iron and steel gas barrel. Report of the Wrought Iron Tubing Inquiry Committee. ANON. *Gas J.* (Supplement) 171, 3–13 (1925).—Appendix II. *Work by the South Metropolitan Gas Co.*—Samples of metal were immersed for definite periods of time in siphon liquor and in distd. water. Results show that the most desirable material is wrought iron of the very best quality without any admixt. of steel. Exposure in a stream of moist coal gas gave the same result. Some samples of material which had given poor service were found to be heterogeneous, a mixt. of wrought iron and steel. Appendix III. *Work carried out by the Gas Light and Coke Co.*—Tests carried out in a closed bottle system, using different electrolytes, different gas mixts., and subjecting the samples to complete immersion, to the action of a film of the electrolyte, and to the action of a current of the gas without and with water, gave results from which conclusions were drawn as follows: (1) CO_2 is not an essential agent for oxidation. Its presence to the extent of $2\frac{1}{2}\%$ in a wet gas contg 1% of O accelerates oxidation about 10%. (2) CO_2 slowly removes Fe in the form of a soln. of $\text{Fe}(\text{HCO}_3)_2$. (3) Liquid water is an essential agent of corrosion. Its effect is more marked when present in small than in large quantities. (4) None of the products of corrosion has a retarding effect upon further corrosion. (5) The relative rates of corrosion are: very pure iron, 100, wrought iron, 150, steel, 190. (6) $(\text{NH}_4)_2\text{SO}_4$ considerably accelerates the rate of oxidation. (7) The chief agencies of corrosion are: O, H_2O , and certain compds. of NH_3 . (8) Rust is formed even with wrought iron although slower than with steel. (9) The soln. of troubles from transported oxides is (a) to cover internal surfaces with protective coating, (b) to remove H_2O completely from the system, (c) and to limit the amt. of O in the finished gas.

A. E. GALLOWAY

Limits of inflammability, and the control of gas mixtures. L. CAUSSÉ. *Gas J.* 171, 394–5(1925).—This summary of C.'s observations is concerned with the control of water gas in gas mixts. by detg. the upper or lower limits of inflammability. A mathematical relation exists between the compn. of a gas mixt. in admixt. with air and the limit of inflammability of each of the constituent gases. If n_1, n_2, \dots, n_p are the proportions of the various gases G_1, G_2, \dots, G_p in the mixt. and N_1, N_2, \dots, N_p the respective upper or lower limits of inflammability of the individual gases when mixed separately with air, $n_1/N_1 + n_2/N_2 + \dots + n_p/N_p = 1$. In a mixt. of 2 gases if m is the proportion of the composite gas M in mixt. with air at the inflammability limit, and if the mixt. M contains x of the gas G and $(1-x)$ of the gas G_1 , then $(mx/N) + m(1-x)/N_1 = 1$ and $x = N(m - N_1)/(m(N - N_1))$. From the latter formula the compn. of the mixt. of 2 combustible gases may be calcd. Either the upper or lower limit may be used but the upper limit is preferable. The limits of inflammability of a mixt. of coal gas and water gas were: upper limit—coal gas 25 to 30%, water gas 70 to 75%; lower limit—coal gas 8 to 10%, water gas 12 to 15%. C. used and describes a modified form of the method of Mallard and Le Chatelier. The app. is a cylinder filled with gas to which is connected a graduated buret filled with air which is emptied by water displacement into the gas cylinder and there mixes with and displaces gas and gas-air

When the level of air in the buret has risen to the assumed limit of inflammability the air cock is closed and the combustion test made. If the result is negative the flame is extinguished and the buret water level raised a division at a time until the limit is reached. The vol. of air a is read from the buret and the limit of inflammability N calcd. by the formula $N = e^{-a}/V$, where V is the vol. of gas in the cylinder

The benzene plant. GG. ILLERT. *Chem.-Ztg.* **50**, 153-4 (1926). —A description of a C_6H_6 plant built by Hirzel (Leipzig-Plagwitz). Illustrated. A. E. GALLOWAY

The central gas producer battery of the Lichtenberg II gas works (Berlin). C. ARNEMANN. *Gas. u. Wasserfach* **69**, 204-9 (1926). —A detailed report of production and heat-balance tests. The battery consists of 5 Allgemeinen Vergasungsgesellschaft type producers gasifying brown coal briquets with low temp tar recovery. The av. total (5 producers) daily throughput was 95.4 metric tons of briquets contg. 11.7% H_2O and 10.5% ash with a heating value of 5215 kg. cal./kg., producing 1.94 cu m. of gas/kg. briquets, its higher heating value being 1866 kg. cal./cu m. (lower, 1744), other yields (% on briquets) being 11.4% of tar and 0.52% of light oil. The cold gas efficiency (higher heating value) was 69.4%, the overall thermal efficiency 86%. The av. gas compn. was CO_2 10.3, illuminants 0.4, O_2 0.3, CO 24.3, H_2 21.8, CH_4 1.1 and N_2 38.8%. Detailed descriptions of the plant are given; it may be noted that these producers are of the water-cooled shell type. W. C. EBAUGH

Purifying gas. HUMPHREYS & GLASGOW, LTD. Brit. 237,920, Aug. 1, 1924. A soln. which has been employed for removing H_2S from gas by formation of a sulfhydrate is oxidized to regenerate the original salt which it contained (with liberation of S) by passing air in fine division through a column of the foul soln. An app. is described.

Eliminating hydrogen sulfide from coal gas. F. W. SPERR, JR. U. S. 1,578,560, March 30. Air after use for regeneration of gas-purifying material is washed with a liquid contg. a freshly pptd. Fe compd. such as $Fe(OH)_2$ to eliminate the H_2S from the air.

Removing naphthalene and similar hydrocarbons from fuel gas. F. W. SPERR, JR. U. S. 1,578,687, March 30. A solvent such as kerosene is recirculated through the flowing gas, and the same gas is subjected to substantially uncontaminated solvent after it has passed through the recirculating stage.

Apparatus for distilling ammoniacal liquor, benzenized oil, etc., or for washing coal gas. J. BARRATT, W. H. GREAVES AND ASHMORE, BENSON, PEASE & CO., LTD. Brit. 237,659, May 6, 1924.

Treating tar water. C. SCHNEIDER. U. S. 1,579,957, April 6. An alkali metal hydroxide is added to hot tar water, and the liquor is exposed to the air and utilized again for cooling gases obtained by the distn. of bituminous fuel.

Oven for distillation of bituminous or other solid materials. O. LASCHER. U. S. 1,576,916, March 16.

Horizontal coke oven. H. B. CARPENTER. U. S. 1,579,075, March 30.

Coke and tar from coal. F. SEIDENSCHNUR. U. S. 1,578,376, March 30. A down-

wardly traveling column of coal is treated with a counter-current of generator gases or other gases free from O at a rate of at least 80-96 cu. ft. of gas per lb. of coal, the temp. of the gas being about 500°.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Petroleum and natural gas in Montana. J. P. ROWE. *Eng. Mining J.-Press* 121, 563-8(1926).

The petroleum reserves of Trinidad. ANON. *Rass. min. met. chim.* 64, 303 (1926).—The most important reserves are petroleum and asphalt. The former varies considerably, showing d. 0.966-0.818 and in %: benzine 0.6-18.3, naphtha 1.7-9.2, kerosene 22.8-43.2, gas oil 0-8.1, lubricating oil 12.8-39.6, asphalt 6.0-56.7, H₂O 0.2-1. The asphalt lake and the geology of the petroleum are also described. C. C. DAVIS

The deposit of bituminous schists at Resiutta (Friuli). GUIDO CONSETTINI. *Rass. min. met. chim.* 64, 29-30(1926).—The deposit comprizes in ascending strata (1) boghead coal, d. 1.32, contg. 36% volatile and giving on distn 30% bituminous oils; (2) fat schist, d. 2.18, contg. 16% volatile and giving 12.5% oils, (3) poor schist, d. 2.30, contg. 7.5% volatile and giving 5.5% oils and (4) dolomite contg. 1% bituminous material. The oil is dark brown with blue fluorescence d. 0.85-0.90, a penetrating garlic odor, partly sol. in EtOH, Et₂O, CS₂, CHCl₃, etc., readily inflammable (leaving no residue), calorific power 11,000, 5.3% org. S, forms black bituminous ppts. with H₂SO₄, HNO₃, or HCl and gives the reaction of ichthyol oils with alc. HgCl₂. It is composed of satd. and unsatd. hydrocarbons of the paraffin and ethylene series, with heterocyclic compds., pyridine and quinoline bases and phenylsulfonic acids. The first portion distils at 80°, the last at 350°. Fractionation yields light oils, d. 0.80-0.82, burning oils, d. 0.850-0.875 and heavy oils, d. 0.950-0.971. Products suitable for solvents of fats, resins and bitumen, driers for varnishes, agricultural insecticides, wood preservatives, alc. denaturants, motor fuel, etc., can be obtained from the schists, of which at least 500,000 tons is available. Among the most important products are ichthyobenzene, ichthyol and its derivs. C. C. DAVIS

Problems of petroleum technology. LEOPOLD SINGER. *Naturwissenschaften* 14, 133-9(1926).—A general review. B. J. C. VAN DER HOEVEN

Oil production and refining in Egypt. M. SAMY. *Oil & Gas J.* 34, No. 34, 138 (1926).—Hurghada, Egypt's largest oil field, produced 159,500 tons of oil in 1924. The oil is heavy mixed-base, brownish black, having a small benzine and kerosene content. Gernsah oil, a high-class paraffin-base oil is dark greenish brown in color, having a benzine content of 8% and kerosene 28%. Abu Durba oil is heavy asphaltic base containing a varying proportion of a waxy resin and having a low benzine and kerosene content. Hurghada crude is run to produce benzine, kerosene, solar (gas) oil, furnace oil, fluxing oil pitch and (in the State refinery) Diesel oil. Gernsah oil produces benzine, kerosene, solar oil and fuel oil. M. B. HART

Economic fuel burning in refining. P. A. MOORE. *Oil & Gas J.* 34, No. 34, 130-2, 136, 176-8(1926).—A discussion of properties of economic fuels and their use. M. B. HART

Chemical investigation of noxious gases in the refining of "viscosine." M. BLINKOFF. *Azerbaidjan Neft. Choz.* 36, 91-3(1925); *Chimie et industrie* 15, 225(1926).—Preliminary report on an investigation of the petroleum industry at Baku. "Viscosine" is the product obtained on refining "nigrol" (residue obtained after removal of kerosene, gasoline and light oils from naphtha). Nigrol is refined by treating with H₂SO₄ and with NaOH, and the chief noxious gas is SO₂, which was detd. by passing the air through I soln., and also by passing it through H₂O soln. An av. of 1.29 mg. SO₂ per l. of air was found during the discharge of the acid sludge, and an av. of 0.51 mg. per l. during other operations. No cases of serious intoxication have occurred, but the gases gradually affect the organism. Better ventilation and the use of masks are recommended. A. PAPINEAU-COUTURE

The refining of mineral oils. H. I. WATERMAN. *J. Inst. Petr. Techn.* 11, 576-82 (1925).—The presence of 1 vol. % of S and halogen compds. in kerosene increased the soot-forming property 10 and 7 times, resp. The Edelmann, silica-gel and Dunstan hypochlorite methods owe their value to their desulfurizing powers. One treatment with 54% of silica-gel decreased the S content of a Persian fraction 20% in two treat-

ments, while 117% of gel by wt. caused a reduction of 60-70% of S in a Mexican kerosene. The Dunstan process followed by filtration through bauxite produced a 68% to 40% reduction in S content. M. B. HART

The importance of the Edeleanu process. H. I. WATERMAN AND J. N. J. PERQUIN. *J. Inst. Petr. Techn.* 11, 560-70(1925); cf. *C. A.* 19, 3371.—The Edeleanu process permits the crude oil distillate to be sepd. into two parts with a loss of less than 1% of SO_2 . The S content of Venezuela kerosene has been lowered 80% and the aniline point has been lowered to 65.2°. A final treatment with 2% oleum improves the color and lowers the S content. M. B. HART

Carborundum furnace assures uniform heat application in oil refining. A. E. NASH. *Oil Trade* 17, No. 2, 49-51, 61(1926).—SiC has a thermal cond. 8-10 times that of ordinary fire brick. A furnace equipped with carborundum muffles within the chamber permits a uniform distribution of radiant heat over the entire shell with no danger of overheated bottoms or tubes. Analysis of waste gases shows an av. of 14% CO_2 . The temp. of the exit gases is reduced and a temp. of 700° F. is produced. Data show a heat loss of 13½% instead of 30% as with normal practice. M. B. HART

The determination of unsaturated compounds in petroleum spirit. W. R. ORMANDY AND E. C. CRAVEN. *J. Inst. Petr. Techn.* 11, 533-6(1925); 12, 48-67(1926).—The Hanus test was applied to det. the unsatd. compds. present in gasoline samples. Results obtained with fractions of a given spirit show that the unsatd. compds. appear to be fairly evenly divided. The mol. wt. of original spirits was detd. by the Victor Meyer method in a coal-gas atm. at 25°, allowances being made for the resinous residue. Aromatics were detd. by the modified Tizard-Marshall method in which the difference of the aniline point of the spirit after washing with 3 vols. of 80% H_2SO_4 and 3 vols. 98% H_2SO_4 is considered to be due to the removal of aromatics. The results obtained with the two acids appear to check within reasonable limits. M. B. HART

Extension of the "critical-solution-temperature" method of analysis of gasoline. M. AUBERT AND E. AUBRÉ. *Compt. rend.* 182, 577-9(1926); cf. Chavanne and Simon, *C. A.* 13, 2125; 14, 117, 464.—In order to avoid removal of aromatic hydrocarbons by nitration, A. and A. det. the critical soln. temp. (CTS) in two different solvents and obtain 2 equations with 2 unknowns: $C(\Theta_{Ac}-\Theta_c)/(100-Ar) = \Theta_{Ac}-[(Ar/k)+T]$ and $C(\Theta'_{Ac}-\Theta'_c)/(100-Ar) = \Theta'_{Ac}-[(Ar/k')+T']$ in which $Ar = \%$ aromatic hydrocarbons, $C = \%$ satd. cyclic hydrocarbons, Θ_c and Θ'_c are the CTS of the cyclic hydrocarbons in the 2 solvents, Θ_{Ac} and Θ'_{Ac} are the CTS of the satd. acyclic hydrocarbons, T and T' are the CTS of the crude mixt. in the 2 solvents, and k and k' are consts. PhCH_2OH has been found very suitable as second solvent; but owing to its ready spontaneous decompn. its purity should be controlled by checking the CTS of a standard hydrocarbon. A. PAPINRAU-COUTURE

The valuation of motor spirit and lubricating oils. HAROLD MOORE. *J. Inst. Petr. Techn.* 11, 571-5(1925).—Minimum tests for lubricating oils are: sp. gr.; viscosity at 70°, 100°, 140° and 200° F.; cold test; flash point; coke test; and appearance. The value of each test is discussed. Addition of 2-10% vegetable oil aids in the maintenance of a film under pressure. Motor spirit tests are: sp. gr., Engler distn. corrosion test and aniline cloud test. M. B. HART

Gasoline manufacture in California. G. W. H. REID. *Oil & Gas J.* 24, No. 31, 238, 9(1926).—A specially prepd. distillate from California crude is used as the absorption medium at the Signal Hill plant of the California Petroleum Co. M. B. HART

Investigation of the composition of cracked spirit. HAROLD MOORE AND R. B. HOBSON. *J. Inst. Petr. Techn.* 11, 587-92(1925).—Expts. were conducted to det. the compn. of cracked spirit produced in a Cross cracking unit, from a refined petroleum from the Russian field. Fractionation and examn. by analysis of the whole spirit and of the fractions are described and the results are given. M. B. HART

The action of sulfuric acid on cracked spirit. C. M. HOUGHTON AND S. BOWMAN. *J. Inst. Petr. Techn.* 11, 583-6(1925).—A method to det. the strength of H_2SO_4 most effective in producing the polymerization of olefins in cracked spirit consists in distg. two 100-cc. samples, one of which has been treated with acid, to the same final b. p. In each case the vol. of reflux from the column into the flask upon removing the flame is measured. The difference between the vols. of the reflux is assumed to be a measure of the polymerization that has occurred. Results are given when low-boiling fractions and also the original cracked spirit are mixed with aviation spirit in a ratio of four to one, showing that 91% is the optimum strength of acid for producing polymerization. M. B. HART

Capillary control in oil and gas reservoirs. S. C. HEROLD. *Oil & Gas J.* 24,

No. 36, 92-3, 96, 98, 100(1926) Time velocity-pressure velocity, pressure-time pressure-volume relations are discussed. M. B. HART

Effect of ozone upon oils. M. A. DOYLE AND R. B. APPLEBY. *Ind. Eng. Chem.* 18, 63(1926).—Olive oil, Velocite B and Redown Engine oil were treated with O varying lengths of time. For all three oils the I number decreased, the acid no., sp. gr. and viscosity increased; for olive oil interfacial tension increases while surface tension and efficiency decrease, and for the other two oils interfacial tension decreases, while surface tension and efficiency increase. Qual. results only are given. W. C. EDWARDS

N. T. U. Company's shale retort. I. S. WISBY. *Pet. Times* 15, 107, 8(1926). A vertical retort charged with 40 t. of shale is ignited at the top. A zone of combustion is set up at the top of the column by a down draft. The distn. is carried on at about 700-800° F. or less. The data obtained upon examn. of Utah shale oil and California oil are given. M. B. HART

The hydrogenation and desulfurization of Norfolk shale oil. H. G. SHAWWILL. *J. Inst. Petr. Techn.* 11, 548-55(1925).—Norfolk shale oil has the following properties: sp. gr. 0.942-0.960, is very mobile, contains up to 7.8% S, 3.4% bases, 3.4% phenols, cresols, etc., 3-4% benzene and toluene. The crude oil contains 20% S free satd. hydrocarbons, 50-60% olefins and diolefins, and 20% S compds. Data are tabulated to show Engler distn. tests, giving sp. gr. and S content of fractions. Data obtained upon hydrogenation and cracking in an atm. of nitrogen show reform losses, sp. gr. and S content. M. B. HART

Lubricants from mixed-base crudes. H. L. KAUFFMAN. *Oil & Gas J.* 24, No. 31, 32, 34, 36, 38, 40(1926).—General practice in lubricant manu. is discussed. Data show yields from pressed distillate when reducing to bottoms of different viscosities, costs of treating, blending tests, physical tests on oils prepd. by blending and those by straight reduction of overhead lubricating distillates or by the reduction of pressed distillates to viscous bottoms. M. B. HART

How will reclaimed oils affect the lubricating oil market? R. B. DAY. *Pet. World (Calif.)* 11, No. 1, 126(1926).—Analysis of used crankcase oil distd. in an Engler flask gave the following results: gasoline 1%, 190; kerosene 15%, 300; lubricating oil 71%, 350; coke and loss 13%. The specifications of the lubricating oil fraction were; Baumé gravity, 31.2, flash point 412° F., viscosity (Saybolt Univ.) 182, unsatd. hydrocarbons 6%. M. B. HART

Paraffin wax and its properties; methods of testing wax and of analyzing oil-wax mixtures. L. D. WYANT AND L. G. MARSH. *Bur. of Mines, Tech. Paper* 368, 26 pp (1925).—For detg. the m. p. of com. waxes, the Am. Soc. for Testing Materials "paraffin wax" method was found best for waxes contg. less than 15% of oil, and the "petrolatum" method for waxes contg. more than 15% of oil. The following procedure was developed for detg. the amt. of oil in oil-wax mixts.: 5 g. of wax was refluxed for a few min. with 35 cc. of MeAc, the soln. was transferred while hot to a 120 cc. test tube, and the flask was rinsed with 15 cc. MeAc. The soln. (contg. 5 g. sample in 50 cc. MeAc) was cooled to 60° F. with vigorous shaking, filtered, and washed with 50 cc. MeAc. The filtrate was evapd. at 212° F. (finally *in vacuo*) and the residual oil weighed, the wax in the sample was calcd. by difference. The wax was dried *in vacuo* at 212° F. and its m. p. detd. If the m. p. was unduly low, the wax was recrystd. as before, from 20 cc. MeAc per g. wax, and the total amt. of oil was taken (for calcn.) as that sepd. by the 2 treatments. If the m. p. of the wax was unduly high, the oil was redissolved in MeAc and a second crop of wax crystals removed. DONALD W. MACARDLE

Analysis of a mixture of unsaturated gases. Determination of erythrene (DOBRYANSKII) 7. Fuel alcohol from brushwood (MARCOU) 16.

BELL, H. S.: American Petroleum Refining. N. Y.: D. VAN NOSTRAND CO. 475 pp. \$5.00
ELLIS, CARLETON and MERES, JOSEPH V.: Gasoline and Other Motor Fuels. N. Y.: A. Van Nostrand Co. 728 pp. \$10

Separating gas, water and oil. D. G. LORRAINE. U. S. 1,577,917, March 23, 1924.
Apparatus for separating fuel oils from water. M. S. GIBB. Brit. 237,768, Oct. 22, 1924.

Electric apparatus for dehydrating crude oil. D. K. CASON, JR. U. S. 1,579,515, April 6.

Apparatus for dehydrating petroleum oil by heating and settling. H. L. EDWARDS. U. S. 1,578,273, March 30.

Thermostat adapted for use in oil refining, etc. R. B. RICHARDSON. U. S. 1,578,208, March 23.

Forming oil stills from metal plates by electric welding. L. R. SMITH. U. S. 1,577,410, March 16. Mech. features.

Vertical oil still. F. E. WELLMAN. U. S. 1,576,563, March 16. A vertical petroleum still is surrounded by an annular combustion space within a furnace setting within the lower part of which a burner is revolvably mounted.

Cracking still and fractionating apparatus for hydrocarbon oils. F. E. WELLMAN. U. S. 1,576,564, March 16.

Distilling oil-bearing sand or similar materials. JACKSON RESEARCH CORPORATION. Brit. 237,757, Sept. 22, 1924. Vapors and gases leaving a condenser are passed through and around the materials undergoing distn. An app. is described.

Treatment of dirty acid obtained in petroleum refining. R. A. HALLORAN, W. N. DAVIS and G. A. DAVIDSON. U. S. 1,579,607, April 6. The dirty weak acid obtained in refining petroleum oil with H_2SO_4 is subjected, while intermingled with a relatively small quantity of fuel oil, to a pressure of over 50 lbs. per sq. in. in a closed retort, and to a high hydrolyzing temp. so that the mass is sepd. into a relatively weak clean acid and a liquid fuel.

Refining oils for gasoline production, etc. R. WILES. U. S. 1,579,799, April 6. Refining and natural gases or other hydrocarbon gases contg. gasoline constituents are subjected to the absorbent action of reduced crude oil, the reduced crude oil is mixed with crude oil contg. gasoline and heavier constituents and the mixt. is subjected to fractional distn.

Distilling hydrocarbon oils. W. C. AVERILL, JR. U. S. 1,577,440, March 23. Oil contg. H_2O is vaporized, part of the vapors of oil and H_2O are simultaneously condensed and remaining vapors are subjected to previously condensed hydrocarbons of higher b. p. obtained from the vapors, which latter are supplied by removing the H_2O collected from the condensed vapors.

Distilling oils with volatile catalysts. A. M. McAFEE. U. S. 1,578,049, March 23. Gas oil or other oils of relatively high b. p. are heated together with $AlCl_3$ or a similar catalyst and vapors of lower boiling oils are led away and condensed after bringing them into intimate contact with added petroleum hydrocarbon oil. U. S. 1,578,050 specifies distg. petroleum oils with $AlCl_3$, partially cooling the vapors to condense out $AlCl_3$ and kerosene, separately condensing and collecting hydrocarbons of lower b. p. than kerosene, sepg. the $AlCl_3$ from the kerosene by settling and returning the $AlCl_3$ to the still. U. S. 1,578,051 specifies distg. oils with $AlCl_3$ and maintaining a flow of oil through a succession of stills. Volatilized and condensed $AlCl_3$ is returned toward the first still of the series.

Catalytic conversion and distillation of hydrocarbon oils. G. L. PRICHARD and H. HENDERSON. U. S. 1,577,871, March 23. Oil of relatively high b. p. is distd. with $AlCl_3$ or the like and vapors of the catalyst and of oil of high b. p. are collected in a second body of heavy oil and catalyst undergoing distn. Vapors of lower b. p. are delivered for final condensation.

"Pyrogenesis" of petroleum oils. E. M. CLARK. U. S. 1,578,802, March 30. Sepd. bodies of relatively heavy oil are confined under pressure within a digester. One of them is heated and vapors thus formed are led over into the second body of oil, abstracting heat from the latter to cause condensation of the vapors of the desired products. Oil displaced by vapor condensation in the second body is fed to the first body of oil and the operation is continued until the second body becomes of substantially lower b. p. than the first body. A substantial conversion is thus effected without other distn. and at a relatively low pressure.

Converting hydrocarbon oils into products of lower boiling point. G. EGLOFF. U. S. 1,579,601, April 6. A bulk supply of crude petroleum or other oil to be converted is externally heated and simultaneously there is produced within the body of the oil an elec. arc to heat it to cracking temp. Evolved vapors are passed through an aerial condenser from which reflux condensate returns to the bulk supply of oil, thence to a condenser and receiver, and the bulk supply of oil is maintained under a self-generated super-atm. vapor pressure.

Cracking hydrocarbon oils. E. W. ISOM. U. S. 1,578,035, March 23. Oil is circulated in a single pass through a heating circuit and heated to cracking temp. by

heating gases which are circulated counter-current to the direction of oil flow. Vapors of the cracked oil are discharged from the heating conduit to a reflux device and the resulting reflux is supplied to the oil-heating conduit adjacent the end of the conduit over which the heating gases first circulate. Fresh oil is supplied to the oil at an intermediate point and part of the heating gases are recirculated in admixture with fresh heating gases. Cf. C. A. 19, 3585.

Electrically heated spiral pipe coil for converting hydrocarbon oils into others of lower boiling point. W. M. McCOMB. U. S. 1,579,554, April 6.

Horizontal still and associated apparatus for converting heavy hydrocarbon oils into lighter products. W. T. HANCOCK and M. BOYLE. U. S. 1,576,742, March 16.

Removing aluminum chloride residues from oil stills. A. M. McAFEE. U. S. 1,578,053, March 23. A caked residue is treated with H-O to disintegrate it into small particles and the latter are flushed from the still. Cf. C. A. 20, 649.

Boat carrying apparatus for recovering naphtha floating on water. A. MEIANI. U. S. 1,573,085, Feb. 16.

Apparatus for testing lubricating properties of oils. A. HENRIKSON, N. A. STEPHENS and V. ZBYSHEVSKI. U. S. 1,578,730, March 30. Lubricating oil for steam engines is tested in a cylinder to which steam is supplied and which contains a driven plunger.

Apparatus for forming lubricating emulsions from oil and water. S. A. BULLOCK and B. T. PERRY. U. S. 1,578,187, March 23.

"Cutting-oil" from mineral oil. E. M. HUGHES. U. S. 1,577,723, March 23. A heavy lubricating oil distillate from mineral oil is treated with mineral acid, e. g., H_2SO_4 , and the ppt. sepd. The remaining acid-contg. oil is treated with alkali, e. g., NaOH, and there is sepd. a pptd. emulsion comprising soap, salt H_2O , some free alkali and unsapon. mineral oil. The soap is decomposed with relatively dil. inorg. acid, e. g., H_2SO_4 , H_2O and salts are sepd. and the remaining product is saponified and mixed with mineral oil to form a cutting oil emulsifiable with H_2O .

Separating wax from lubricating oil. E. PETTY. U. S. 1,577,852, March 23. Mineral-oil lubricating stock contg. wax is dild. with a light petroleum distillate and agitated with an acid, e. g., H_2SO_4 . The sludge is sepd. and the acid-treated stock is treated with alkali, soap and H_2O are removed from the stock and a clarifying and decolorizing agent such as fuller's earth is mixed with the stock and then sepd. The stock is chilled and centrifuged to sep. wax and a portion of the dilg. agent from the remainder of dilg. agent and oil. Cf. C. A. 20, 109.

Sulfonating products from gilsonite. C. N. FORREST, H. P. HAYDEN and O. R. DOUTHETT. U. S. 1,578,235, March 23. A sulfuric purification process for gilsonite material is described from which there is obtained a fat-splitting sulfonic product, useful also as a detergent. Cf. C. A. 19, 1773.

Steam treatment in kilns for preserving resinous lumber and recovering by-products. W. H. MASON. U. S. 1,577,044, March 16.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Report of the Chief Inspector of Explosives of the Bureau for the Safe Transportation of Explosives and Other Dangerous Articles. B. W. DUNN. B. E. Rept. No. 19, Mar., 1926, 71 pp.—Although over 500,000,000 lbs. of explosives were transported by the railroads of the U. S. and Canada during the calendar year 1925, they were involved in but 26 accidents causing a property loss of \$11,702 and giving rise to no casualties. All of these 26 accidents were due to fireworks, 24 of them being caused by toy torpedoes. chiefly because of excess charges in them. The most frequent cause of accidents, 608 in no., was "Inflammable liquids" chiefly gasoline, causing a loss of over \$830,000. The next most frequent, 547 in no., was "Acids and Corrosive Liquids," causing a loss of over \$35,000. The next most dangerous substances in the order of frequency of accidents were "Inflammable Solids and Oxidizing Materials," 166, "Compressed Gases," 72, "Explosives," 26, "Poisonous Liquids and Solids," 10, with "Unlisted Semi-dangerous Articles," 82. The totals from all accidents were: killed 13, injured 57, loss \$1,056,178. The personal injuries attendant on handling compressed gases were with those contg. Cl, Pintsch gas, or He. Five of the 6 from Cl resulted from a single cylinder shipped in violation of the regulations. In the case of the Pintsch gas the fatality was due to effects of fumes from a supposed empty cylinder. That of He was due to rough handling of a compressed-gas cylinder. A large item of loss resulted from a freight train carrying

C_2H_2 cylinders being derailed by flood. The immersion caused a short circuit of the storage batteries in the car and the resultant flash ignited escaping gas causing explosion and fire. There were many blow-offs, principally of CO_2 cylinders, during extremely hot weather. Among the accidents from poisons was that of fumes from a damaged shipment of $Ca(CN)_2$ which severely affected 15 men. The rept. from the Chem. Lab. by Charles P. Beistel records tests of imported tooth brushes whose handles of a pyroxylin plastic were of such low stability as to be liable to ignition in transit. An interesting investigation was that of cars in which As_2O_3 had been transported with a view to their subsequent suitability for transporting foodstuffs. From 0.02 to 0.60 percent of As_2O_3 was found in the swept and washed cars. It was advised that in shipping As_2O_3 containers be used that will not permit of leakage or sifting of the contents. A CS_2 emulsion for use as an insecticide was found to give off inflammable vapors at all temps. above freezing. In tests of HNO_3 carboys, one a wooden box using mineral wool for packing, the other a wooden box having wood strips for cushioning, when the carboys were punched and broken so as to allow the HNO_3 (d. 1.4) to escape, the first carboy took fire as a result of the action of the acid on the mineral wool producing heat, and to its holding the acid longer in contact with the wood. Tests of Ascoloy, an alloy of steel contg. C 0.01% and Cr 12-14%, showed it to be suitable for drums or tank cars for HNO_3 . Tests of pressures of commercial HCl at various temps. led to the opinion that pressures from these causes in tank cars will not be such as to damage a steel shell of the strength ordinarily used in tank car construction. A shipment of H_2SO_4 in metal barrels was condemned because its d. was less than 65° Bé. Many appendixes give detailed descriptions of accidents. C. E. MUNROE.

The ignition point of gases at different pressures. III. H. B. DIXON AND W. F. HIGGINS. *Mem. Proc. Manchester Literary and Phil. Soc.* 70, 29-36(1926); cf. C. A. 20, 290.—Combustible gas being introduced from a 2-mm. orifice at the upper end of a 4-mm. tube which is at the center of a 12-cm. vertical tube through which air is passed upwards, the whole being heated in an elec. furnace, the ignition temp. must be expressed in terms of the time lag of ignition after turning on the gas, since mixing and slow combustion cause delayed ignition at lower temps. For expts. under pressure the whole furnace was enclosed in a steel jacket and suitable inlet and outlet valves were provided. The following data for H_2 -air, H_2 - O_2 , CH_4 -air and CH_4 - O_2 mixts., resp., at atm. pressure, are illustrative of the more complete data tabulated; lag 1 sec., 620° , 617° , 728° , 657° ; lag 5 sec., 588° , 587° , 678° , 619° ; lag 10 sec., 577° , 576° , 657° , 602° . The foregoing represent the most uniform conditions of heating of the tube (after enclosure in the steel jacket, but at atm. pressure); less uniform conditions in the non-jacketed furnace gave higher ignition temps. for the same lag, the difference being less than 15° up to 2 sec. lag, but for CH_4 -air mixts. at 15 sec. lag it was 45° high. Increasing the pressure on CH_4 -air mixts. decreases the ignition temp. regularly; for 1 and 2 sec. lag, resp., the temps. were 100 mm., 804° , 782° ; 400 mm., 747° , 717° ; 760 mm., 728° , 710° ; 2 atm., 711° , 690° ; 3 atm., 695° , 680° ; 5 atm., 666° , 652° ; 7 atm., 644° , 633° . For H_2 -air mixts. increasing the pressure (from low pressures) first increases the ignition temp. rapidly, finally decreasing it slowly; for 1 and 2 sec. lag, resp., temps. were 100 mm., 521° , 519° ; 200 mm., 554° , 549° ; 400 mm., 592° , 581° ; 600 mm., 614° , 601° ; 760 mm., 620° , 606° ; 1000 mm., 623° , 609° ; 1520 mm., 619° , 608° . For H_2 - O_2 mixts. a similar max. ignition point is noted, but at 200 mm. instead of at 1000 mm. W. B. P.

An explosion with potassium. J. G. F. DRYCE AND E. J. WEEKS. *Chem. News* 132, 193(1926); *Chem. Age* (London) 14, 248.—In a lecture demonstration of the properties of K, a knife was stuck into a piece of K to remove it from the bottle. A violent explosion occurred. It is suggested that the explosion may have been due to the presence of K carbonyl. E. H.

Precautions in working with low temperature baths. A. MITTASCH AND E. KUSS. *Chem.-Ztg.* 50, 125(1926).—Disastrous explosions are cited, one from cooling C_2H_2 with liquid air, another from cooling nickel carbonyl with liquid air. Both were probably due to leaks in the container which allowed liquid air to reach the condensate. Combustible materials must never be cooled with liquid air unless a metal condensing vessel is used, and liquid N_2 is preferable. If a Cu beaker, 10 cm. diam. by 40 cm. high, is suspended in a 15×60 cm. metal Dewar flask and liquid air circulated between the two, 0.75 l. pentane may be cooled to -150° in 15 min. W. L. BADGER.

Experiences in making cooling baths from organic materials and liquid air. F. A. HENGLEIN. *Chem.-Ztg.* 49, 1037(1926); cf. Biltz, C. A. 20, 824.—More than a hundred mixts. were prepd. and used by the author and his pupils without bad results. The materials used were Et_2O , $AcOEt$, $C_6H_5CH_3$, CS_2 , benzene, C_6H_5Br , anisole, C_6H_5N , $CHCl_3$, and mixts. of Et_2O and CS_2 . Only 2 explosions resulted, both with CS_2 .

these were due to the formation of a crust above the liquid air when CS_2 was dropped into it, so that the evapg. liquid air could not escape. No ignition of the CS_2 occurred
W. C. EBAUGH

Special properties of sulfuric cellulose esters (CAILLE) 25. Regions of reaction (JORISSEN) 2.

BEYERSDORFER, PAUL. Staub-Explosionen. Dresden and Leipzig, Theodor Steinkopff. ix + 125 pp.; 5.50 marks (paper) and 7 marks (bound). Reviewed in *Rev. chim. ind.* 35, 96-7(1926)

Drying smokeless powders. J. C. VICKERY and M. H. DAVIS. U. S. 1,579,262, April 6. A gaseous carrier is partially satd. with solvent vapors such as ether and alc. by spraying the heated solvent into the air or other gaseous carrier, the temp. of the latter is raised and it is passed over the powder to be dried and then through a spray chamber and reused in cyclic operation until the powder is sufficiently dried.

Removing coloring substances from smokeless powder. E. C. PITMAN and G. F. HUNTER. U. S. 1,577,075, March 16. The powder is subjected to the action of dil. HCl or of other dil. acid capable of rendering sol. coloring substances without injury to the powder and the solubilized substances are dissolved out with a solvent such as alc.

Machine for packing gelatin dynamite or similar explosives G. JOHNSON. U. S. 1,578,036, March 23.

Cartridge wad. A. G. SCHURICHT and G. T. WRIGHT. U. S. 1,576,759, March 16. Wads are formed of a compressed mixt. of cork flour or similar bindable material and polymerized China-wood oil.

Explosive mixture for disseminating military poisons or other toxic substances. W. O. SNELLING. U. S. 1,579,964, April 6. Nitrated starch is mixed with diphenyl-cyanoarsine or other non-explosive toxic material, and the mixt. is detonated.

Waterproofing matches. H. D. SCHMIDT. U. S. 1,579,401, April 6. A mixt. of beeswax 4, sealing wax 3 and rubber cement 6 parts is used with sufficient gasoline to produce a liquid compn.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Electro-capillary analysis of coloring materials. W. KOPACZEWSKI. *Rev. gén. mat. color.* 30, 34-44(1926); cf. *C. A.* 19, 2436.—Dyes in the colloidal state and of a concn. not greater than 1% may be classified as acid, basic and amphoteric. The acid dyes show about the same ascension in filter paper as pure water, basic dyes hardly exceed the level of emergence of the strips of filter paper, amphoteric dyes are indicators and are characterized by the appearance of zones of color changes. The rate of electro-capillary ascension of electronegative and of amphoteric dyes with relation to water is greater than that of positive dyes. The rate of ascension varies directly as the degree of micellary dispersion. Electrocapillary analysis is a means of detg. the relative rates of imbibition of salts and colloids, and of detg. variations in viscosity and surface tension of liquids.

Spectrophotometric evaluation of dye mixtures. W. C. HOLMES. *Am. Dyestuff Rept.* 15, 189-91(1926).—The methods in use in the Color Lab., Bur. of Chemistry, Washington, are described
L. W. RIGGS

Action of sulfur on monochloroanilines. H. H. HODGSON. *J. Soc. Dyers Colourists* 42, 76-80(1926).—The structure of sulfide dyestuffs was studied. The action of S on a large no. of simple aromatic amines was examd. to ascertain the fundamental processes which may be involved in the general complex reaction resulting in the final production of colored substances. The thionation of *o*-, *m*- and *p*-chloroaniline is described in
L. W. RIGGS

268°; when coupled with Naphthol AS-D formed long scarlet needles, m. 272°.

L. W. RIGGS

Constitution of Hansa Yellow G (MLB) and other yellow pigment colors. F. M. ROWE, A. H. BURR AND S. G. CORBISHLEY. *J. Soc. Dyers Colourists* 42, 80-2(1926).—A quantity of the coloring matter was made by coupling diazotized *m*-nitro-*p*-toluidine with acetoacetic anilide, the product being in all respects identical with Hansa Yellow G. Monolite Yellow G(BDC) and Pigment Fast Yellow HGL conc. new (JWL) were found to be identical with Hansa Yellow G (MLB).

L. W. RIGGS

Satin white as the foundation for coal-tar lakes. A. COBENZL. *Farbe u. Lack* 31, No. 4, 40(1926).—A short note on the prepn. and use with lakes, of satin white.

R. J. MOORE

Dyeing apparatus for naphthol AS. KARL REIK. *Textilber.* 7, 234-7(1926).

E. R. CLARK

Various precipitation formulas and practical yields. ANON. *Farbe u. Lack* 31, No. 8, 90; No. 9, 102; No. 10, 111(1926).—A list of the most important dyes for the prepn. of dry colors, with numerous formulas and methods of pptn. R. J. MOORE

(Printing) red or white on a dark indigo (ground). JOSEPH POKORNY. *Bull. soc. ind. Mulhouse* 91, 759-61(1926). Sealed notes 2318 of April 24, 1914, and 2328 of June 22, 1914.—According to Jos. Skoupil the mercerized fabric is dyed a deep indigo, prepd. with Na-naphthol, printed with a paste contg. approx. 1 mol. of MnO_2 , 1 mol. $PbCrO_4$, 1 mol. of $NaClO_3$ and diazo-*p*-nitroaniline (the diazo being omitted for whites, steamed 3-4 min. in a small Mather & Platt, passed 3-5 sec. in 17° Bé. HCl (contg.) 30 g. $FeSO_4$ per l.) at 37° C., steamed 35-40 sec. at 35°, washed, treated cold with 40 Bé. HCl to remove excess of Mn, rinsed, and washed with soap. The red or white is perfect and the fabric but very slightly attacked. In com. operations a no. of pieces turned out a dirty orange instead of bright red, and P. found that: (1) the dirty orange is produced when the printed goods are not put through the small Mather-Platt; (2) a good red is obtained without the $NaClO_3$; (3) the presence of MnO_2 is unnecessary and a perfect red can be obtained with $PbCrO_4$ alone. He recommends the following process: dye the unmercerized fabric a deep indigo, prep. with Na-naphthol, print with paste contg. $PbCrO_4$ (but no MnO_2 or $NaClO_3$), pass through 17° Bé. HCl at 37° C. for 3-5 sec., steam 35-40 sec. at 35°, and wash. This treatment is easier both on the blue and on the fabric. P. found that in discharging the indigo to a white perfect results are obtained without the use of $NaClO_3$, and that quite an acceptable white is also obtained by omitting the $NaClO_3$ and reducing the MnO_2 by half. Report. PIERRE SEYDER. *Ibid* 762-4.—The principle of discharge by means of oxidizing agents was used as early as 1825 by Thompson, and the novelty of P.'s process lies in the method of application rather than in the choice of oxidizing agent. S. easily duplicated P.'s results, obtaining perfect reds, and whites that were excellent on small objects but slightly yellowish on larger surfaces. On progressive bleaching with hyposulfite followed by dyeing with methylene blue, the portions of the fabrics which had been printed had greater affinity for the methylene blue, showing the presence of oxycellulose; and the pieces printed *via* Skoupil showed the presence of a larger amount of oxycellulose than those printed *via* P.

A. PAPINEAU-COUTURE

Fast discharge-colors on indigo. CH. SUNDER AND R. SOLBACH. *Bull. soc. ind. Mulhouse* 91, 755-7(1925). Sealed note 2171 of April 22, 1912.—In order to prevent simultaneous reduction of the indigo and of the vat dyes when using pastes contg. indanthrene or helindone dyes to discharge indigo, $Sn(OH)_2$ is used instead of the $Zn(O)$ generally employed in rongalite CL + anthraquinone discharge pastes. The indigo is thus reduced by the hyposulfite, while the vat dyes are subsequently reduced by the $Sn(OH)_2$ on passing through the NaOH bath. Three formulas are given for red, yellow and blue, resp. Report. OSCAR MICHEL. *Ibid* 757-8.—The process described in D. R. P. 263,647, applied for July 30, 1912, granted Dec. 23, 1912, uses ZnO + $FeSO_4$ + a Sn salt, and is very similar; but the process of S. and S. is anterior to it. A. P.-C.

Practical hints on the production of bright colors on textile fabrics. RAFFAELE SANSONE. *Am. Dyestuff Rept.* 14, 536-40, 596-600, 628-30(1925); cf. C. A. 19, 2748.

L. W. RIGGS

Dyeing of acetate silk. H. R. DAVIES. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 101-7; *Am. Dyestuff Rept.* 15, 197-203(1926).

L. W. RIGGS

Dyeing acetate silk. CHAS. E. MULLIN. *Am. Dyestuff Rept.* 14, 517-21, 588-93, 622-7, 653-8, 694-9(1925); cf. C. A. 19, 2748.—Acetate silk—its dyes and their application; supplemental to the preceding series of articles on dyeing of acetate silk.

Ibid 747-52, 765, 787-91, 849-50, 893; 15, 1-2, 38-9, 43-4, 69, 81-5, 139-42, 153-6, 181, 191-3, 223.

The dyeing of cellulose-acetate silk. I. VALENTIN KARTASCHOFF. *Helvetica Chim. Acta* 8, 928-42(1925).—Theoretical and exptl. evidence is given to support Witt acetate (to which I closely corresponds) was shown by cataphoresis expts. to have a negative charge in contact with water. The course of dyeing of I fibers by Celatene dyes (aminoanthraquinone derivs.) was followed under the microscope, and was found to be a dissoln. of the particles of the dyestuff by the fiber. Dry fibers in contact with dry, finely powdered dianisidine were dyed a fast brown shade in 15 days (probably dissolved by the fiber could be partially diazotized and coupled. The use of this method with Celatene dyes gave results brighter and faster than those obtained by the usual method. A rather complete literature and patent review of dyestuffs and dyeing methods for I is given.

The theory of dyeing of acetate rayon. V KARTASCHOFF. *Textilber.* 7, 28(1926).—The partition coeffs. of a number of dyes between the fiber and water and between water and EtOAc are of the same general order of magnitude, indicating that dyeing proceeds by a process of soln.

The dyeing of non-denitrated nitro type rayon. KURT H. MEYER, CURT SCHUSTER AND W. BÜLOW. *Textilber.* 7, 29-30(1926).—The dyeing of this fiber proceeds by soln. similarly to the dyeing of acetate rayon and similar dyes may be used. The soly of $H_2NC_6H_4NO_2$ in the fiber is over 100 times its soly in H_2O . The rate of diffusion of such materials into undissolved and hence unspun nitrocellulose is much less than for the spun product, but the ultimate equil. is the same.

Fine-fibered rayon by the copper process. WILHELM HANKE. *Textilber.* 7, 38-40 (1926).—In the method described, dusted linters are cooked twice, first with 3.5% NaOH, and a little $Na_2S_2O_4$, and then with perborate and a bleachers' oil. The product is thoroughly macerated in the hollander and mixed with $Cu(OH)_2$ obtained by pptn. with NaOH. From 1.6 to 1.75 kg. $Cu(SO_4)_2$ is used to each kg. of cellulose. This mixing is done at 15°. The resultant mass is mixed with 125 l. 25% NH_4OH per kg. of cellulose, let stand 30 min., stirred for an hour and again allowed to stand. After some 8 hrs. the stirring is again started, and continued until the desired spinning conditions are attained. The soln. is filtered through Ni wire cloth and the excess NH_3 recovered in a vacuum app. Some 5-6.5% of NH_3 is left in. Spinning is done by the methods of D. R. P. 220,051 and 303,017 in most works, but a new method is described which utilizes a stream of water to produce the stretch.

Will acetate rayon supersede older types? E. SCHULKE. *Textilber.* 7, 25-6 (1926).—Physical tests, especially wet tensile strength, show that substantial improvements must take place first.

The ripening of viscose. RUD BERNHARDT. *Kunstseide* 1, 193-8(1925).—Chem. changes accompany changes in particle size in the ripening of viscose. The amts. of CS_2 given off by boiling viscose solns. of varying ages with dil. H_2SO_4 in a stream of H_2 show that a dicellulose xanthate, $NaSCSO(C_6H_5O)_2OH$ is first formed and that this eventually changes completely to tetraxanthate of equivalent formula. Remarks. R. O. HERZOG. *Ibid* 261-2.—B used methods inferior to those of H and associates who published first. Reply. BERNHARDT *Ibid* 284-5. Comment. LEUCHS. *Ibid* 286.—B. failed to distinguish between xanthate S and by-product S.

The practical side of viscose-rayon manufacture. H G DAHLNVORD. *Textilber.* 7, 56-9(1926).—Describes some German made machinery with illustrations.

Wool-like viscose fibers. E. SCHULKE. *Textilber.* 7, 36-8(1926).—*Snafil* has developed from the early patents of Beltzer (D. R. P. 271, 215), and Pellerin and Girard (Fr. P. 410,776, 466,292 and D. R. P. 266,140) (followed by the war-time production of "Stapelfaser") Increased fineness is the most noteworthy improvement of the last few years in prepg. such spinnable fibers. *Snafil* and wool mixts. give fabrics which do not shrink and felt in washing and yet have high warmth-retaining value. The production of finer denier rayon will give a better tow for carding.

Special properties of sulfuric cellulose esters. ABEL CAILLE. *Chimie et industrie* 15, 189-92(1926); cf. C. A. 19, 1495, Kuecht and Thompson, C. A. 16, 1872—By immersion of strips of cotton in 20, 30, 40, 50 and 60% solns. of H_2SO_4 in AcOH for 30 min. sulfocelluloses were obtained contg. 4.37, 4.49, 5.70, 8.83 and 7.48 g H_2SO_4 per kg., resp. Tensile strength and dyeing tests showed a gradual increase in strength and in affinity for basic dyes with increase in H_2SO_4 content, but the 60% soln. attacked

the fiber, reducing the strength and also the affinity for basic dyes as compared with the ester contg. 8.83 g. H_2SO_4 . The affinity of the various samples for acid dyes was found to be the same as that of untreated cotton. Three portions of a nitrocellulose contg. 12.5% N were treated as follows: (1) washed 20 min. in distd. H_2O , (2) completely stabilized *via* Hervé to eliminate combined H_2SO_4 , (3) washed 20 min. with tap H_2O and then stabilized *via* Hervé. They contained the following amts. of total and of neutralized H_2SO_4 : (1) 0.0967, nil; (2) trace, —; (3) 0.052, 0.046%, resp. Both (1) and (3) had a decidedly greater affinity for methylene blue and rhodamine than (2). Com. nitrocellulose rayon after stabilizing *via* Hervé (total H_2SO_4 0.19, neutralized H_2SO_4 0.17%) had much less affinity for methylene blue than before stabilizing (total H_2SO_4 0.58, neutralized H_2SO_4 0.18%). Cellulose acetate gave similar results, but the difference in affinity of the stabilized portions was not as pronounced as with nitrocellulose. Quant. detns. of the amt. of dye (methylene blue and auramine) absorbed by the treated and untreated esters confirmed the above results, and showed that the combined H_2SO_4 has the same effect on the affinity whether or not it has been neutralized with Ca and that the nitrate radicals have very little, if any, effect on the affinity. C concludes that the fixing of basic dyes by cellulose products is not due solely to the presence of oxycellulose, but may also be due to sulfuric esters, which are mainly responsible for the affinity of nitrocellulose (even when denitrated) and acetylcelluloses. The dyeing is not a chem. phenomenon, as the amt. of dye fixed by the cellulose ester is not proportional to the total H_2SO_4 content.

A. PAPINEAU-COUTURE

The fine structure of rayon and its resistance to enzymic activity. P. KARRER. *Textilber.* 7, 23-4(1926).—The rate of soln. of various types and modifications of cellulose in cellulase preps. varies greatly, e. g., in a comparative test a com. Cu rayon lost 10% as against 57% for a lab. viscose prepn. Each gave a low Cu number, and the X-ray interference diagrams obtained were similar. The difference is possibly due to variation in micelle arrangement and surface exposure. Rayon of the same but different denier showed similar loss. Mercerized cellulose is much more vigorously attacked than unmercerized. Cellulose is not completely saccharified by cellulase and must be considered as two substances which differ in enzymic resistance. "Milky" viscose rayon showed unusually rapid bacterial resolution into sol. products. The method is recommended for further study and investigation.

E. R. CLARK

Bleaching rayon with activin. RICHARD FEIBELMANN. *Textilber.* 7, 47-8(1926). The stable nature of activin makes it especially suited to the bleaching of rayon. In a neutral soln. cream shades are obtained. Acid solns. give a good white without tendering.

E. R. CLARK

Bleaching with peroxides. T. D. AINSLIE. *Proc. Am. Assoc. Textile Chem. Colorists* 1926, 107-13; *Am. Dyestuff Rept.* 15, 203-9(1926).

L. W. RIGGS

Cold bleaching (of cotton) as opposed to boiling bleaching. M. FREIBERGER. *Textilber.* 7, 148, 226-7(1926).—The Mohr system is uneconomical, dangerous to the goods, and not particularly new.

E. R. CLARK

The behavior of fibers toward colloidal solutions. W. HERBIG AND H. SEYFERTH. *Z. deut. Oel-Fett-Ind.* 46, 81-4(1926); illust.—To obtain a definite measure for the ease with which fibers become "wetted" by solns. used for textiles, H. and S. made attempts to develop a lab. method (1) by measuring the rise of a liquid in a standard thread under fixed conditions, (2) measuring the horizontal distance that a liquid will travel in thread in a given time, and (3) by measuring the time elapsing before a drop of 0.05 cc. falls and disappears through a number of parallel threads stretched under a given tension. While each method yielded interesting information, none gave consistent data.

P. ESCHER

Estimating the degree of mercerization. HALLER. *Textilber.* 7, 65-6(1926). It has formerly been proposed to det. the degree of mercerization by comparing the depth of shade produced by dyeing with direct colors with that of standards, etc. When the shades produced are measured on the Ostwald chromometer, the percentage of black gives a good measure of the property in question.

E. R. CLARK

The manufacture of waterproof fabrics. HUGO JAEGER. *Textilber.* 7, 140-56(1926).—A number of recipes covering metallic soaps, drying oils, waxes, CuO-NH_3 , etc., are given together with descriptions of useful app.

E. R. CLARK

Historical notes on the development of chemical finishes for cotton. A. BODMER. *Textilber.* 7, 232-4(1926).—Samples of recent Heberlein H_2SO_4 finishes are attached.

E. R. CLARK

Some effects of humidity on the properties of fabrics, with special reference to the control of humidity during strength tests. R. G. PARKER AND D. N. JACKMAN. *J. Soc. Chem. Ind.* 45, 47-54T(1926).—Perfectly dry fibers take up moisture from the atm.

and attain their equil. rapidly, the H_2O content at 70% relative humidity varying from 6 to 12.4% in the order celanese, cotton, linen, silk, wool, viscose. Mullen bursting strength tests upon samples of fabric in equil. with atm. of varying relative humidity showed a slight increase in strength for cotton and mercerized cotton with rising humidity. Linen increased 25% when wet. Other fabrics lose in strength as the humidity rises. These changes are temporary and the fabric reverts to its original strength when reconditioned at normal (70%) humidity. One % Na oleate soln at 60° decreases the strength of silk and wool, but has no further effect on rayon. The oleate soln weakens wool silk, and celanese to a greater extent than 1% Na_2CO_3 . T S C

Finishing cotton goods with activin-treated starch. RICHARD FEHDELMANN *Textilber.* 7, 144-6(1926).—Starch may be modified with activin rather than by fermentation, etc., and the process is easily controlled. E R CLARK

Studies on the action of starch-modifying agents. HALLER AND A HOHMANN *Textilber.* 7, 239-42(1926).—Some quant. viscosity data which show the superiority of activin to various diastase preps and other chemicals. E R CLARK

Use of the microscope in the textile laboratory. L. G. LAURIE *J. Soc. Dyers & Colourists* 42, 73-6(1926). L. W. RIGGS

Studies on the bacterial decay of textile fibers. II. A preliminary study of the deterioration of samples of artificial silk through the action of microorganisms. A. C. THAYSEN AND H. J. BUNKER *Biochem. J.* 19, 1088-91(1925), cf. Fleming and Thaysen, *C. A.* 15, 3556.—The rate of destruction of artificial silks by microorganisms varies considerably, being slowest in the case of cellulose acetate silk and quickest in the case of cuprammonium silk. III. The occurrence of humus compounds in deteriorated fabrics and the bearing of their formation on the origin of peat and coal. A. C. THAYSEN, W. E. BAKES AND H. J. BUNKER. *Ibid.* 20, 210-6(1926). Microbiological activity does not eliminate all the cellulose present in plant tissues decaying to form peat. Humic compds. obtained from peat consist of two varieties (a) one which yields a Cl deriv. similar to "natural humus" and (b) another which gives a Cl compd. closely related to the artificial humus compds. obtained when morg. acids act on carbohydrates or when cellulose fibers decay through aging. BENJAMIN HARROW

Use of aminohydroxystilbolic acids in the dyeing of skins (CASABURI) 29.

CHAPLET, A. Soies artificielles. 2nd edn. Paris, 1925. Gauthier-Villars. 267 pp.; 40 francs. Reviewed in *Rev. chim. ind.* 35, 96(1926).

KÖNIGSBERGER, CARL. Die deutsche Kunstseiden- und Kunstseidenfaserindustrie in den Kriegs- u. Nachkriegsjahren u. ihre Bedeutg. f. unsere Textilwirtschaft. Berlin: W. de Gruyter & Co. 172 pp. R. M. 5.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. *Brit.* 237,872, Aug. 2, 1924. Aminoanthraquinone-acridone and -thioxanthone dyes are obtained by condensing a 1,3,5-triazine deriv. halogenated in the nucleus with a 4-aminoanthraquinone-4'-halo-1,2-thioxanthone or -acridone. Some of the products may be condensed with other compds. simultaneously or subsequently. They dye cotton from the vat in violet, blue, brown, green, gray and other shades. Numerous examples are given.

Vat dye. A. LÜTTRINGHAUS, H. NERESHEIMER and H. EMMER. U. S. 1,580,062, April 6. Benzanthrone is acted on by alkali metal alcoholate at such a high temp. (usually about 170° or higher) that the benzanthrone is substantially completely converted into a dye.

Dyeing apparatus. SMITH, DRUM & CO. *Brit.* 237,712, July 8, 1924.

Dyeing apparatus. H. M. DUDLEY. U. S. 1,577,311, March 16.

Dyeing apparatus. H. E. VAN NESS. U. S. 1,577,881, March 23.

Yarn-dyeing apparatus. J. SCHLUMPE. U. S. 1,579,956, April 6.

Apparatus for dyeing yarn. G. T. THOMAYER. U. S. 1,579,040, March 30.

Apparatus for dyeing or other treatment of hosiery or other fibrous materials.

H. M. DUDLEY. U. S. 1,577,315, March 16.

Apparatus for dyeing or other treatments of yarn in hanks or skeins. H. M. DUDLEY. U. S. 1,577,312 3-4, March 16.

Fast dyeings on wool. H. KRZIKALIV, H. KAMMERER and J. NÜSSELEN. U. S. 1,579,121, March 30. Wool or other animal fiber is charged with a sulfonated naphthalene deriv. such as 2-benzoylamino-3-hydroxynaphthalenesulfonic acid and then treated with a diazo compd., e. g., diazotized *m*-xylidine.

Designs on textile fabrics. HEBERLEIN & CO., AKT. GES. *Brit.* 237,009, July

29, 1924. Fabrics woven with "acetate silk" or the like and cotton, wool, silk, viscose, mercerized cotton, cuprammonium or nitrocellulose silk or with mixts. of these are printed with a resist such as glue, alc. shellac soln., a thickened soln. of Na_2CO_3 , K_2CO_3 , NaOH or KOH , and then treated with a solvent for the "unresisted" acetate silk such as CHCl_3 , acetone, pyridine or epichlorohydrin. The fabric may also be dyed or printed.

Dyeing or printing cellulose acetate. BRITISH DYESTUFFS CORPORATION, LTD., W. H. PERKIN and S. C. BATE. Brit. 237,739, Aug. 22, 1924. "Acetyl silk" is dyed in a neutral, acid or alk. dye bath or printed with "sulfato" compds. of monoazo dyes, preferably nitrated monoazo dyes. Numerous examples are given, including procedure for dyeing mixed goods.

"Viscose silk." A. KÄMPF. U. S. 1,579,711, April 6. Freshly spun "viscose silk" is subjected to a vacuum of sufficient strength to remove rapidly and completely the CS_2 from the fiber, and is afterward washed.

Viscose. H. DREYFUS. U. S. 1,578,588, March 30. A cellulosic material in association with caustic alkali is subjected to the action of CS_2 in C_6H_6 . The caustic alkali is used in not more than an equimol. proportion with the cellulose and the quantity of CS_2 is 0.2-0.5 of a mol. proportion.

Filaments and films from viscose. W. MENDEL. U. S. 1,576,529, March 16. Undesirable S compds. are removed from viscose products, after forming in an acid bath and before drying, by the action of Na_3PO_4 . U. S. 1,576,530 specifies pptg. viscose in an aq. soln. contg. NaHSO_3 and treating with Na_3PO_4 . U. S. 1,576,531 specifies pptg. by heat and treating with Na_3PO_4 .

Apparatus for acid-carbonization of textile materials. A. SHAW and B. SHARP. Brit. 237,713, July 9, 1924.

Weighting fibers. O. BERG and M. IMHOFF. U. S. 1,579,628, April 6. Silk or other fiber to be weighted is preliminarily weighted with Sn by any known method, which includes the use of a fixing bath, and is then treated with Pb acetate or other sol. Pb compd. to increase the weighting.

Lustrous fabrics. A. GELBERT. U. S. 1,578,981, March 30. An ordinary fabric such as cheese cloth or calico is treated with a soln. of a crystallizable salt such as CaBr_2 or other fireproofing salt and after drying is further treated with a gelatinous soln.

Degumming, bleaching and dyeing silk. H. B. SMITH. U. S. 1,578,933, March 30. A hot bath contg. H_2O_2 and a dye such as rhodamine B or the sky-blues 6-B is used for combined degumming, bleaching and dyeing treatment.

Mercerizing textile materials. F. B. VOEGELI. U. S. 1,577,393, March 16. The goods are subjected to hot caustic baths, squeezed and mangled, and then cooled and stretched.

Treating tow or other fibrous material with sulfur dioxide or other insecticidal gas and compressing it. J. E. LAPPEN. U. S. 1,577,240, March 16.

Absorbent fibrous composition. J. O. GOODWIN. U. S. 1,579,925, April 6. An absorbent material adapted for use in making footwear or floor coverings comprises cotton or other fibrous material and partially coalesced particles of prevulcanized rubber.

Rubberized felt. R. B. RUSSELL and H. BROOMFIELD. U. S. 1,579,890, April 6. Fibers are impregnated with rubber latex during a felting operation, the latex is coagulated, and the material is subjected to pressure and dried.

Hair felt. A. L. CLAPP. U. S. 1,577,955, March 23. A felt is formed of hair and a leather soln. which is pptd. on the hair, e. g., by use of alum and a soln. of scrap leather in caustic alkali.

Brattice sheeting. C. D. ABRAHAM. U. S. 1,577,890, March 23. A fabric such as duck or drill is impregnated with NH_4 phosphate to render it fire-resistant, and then coated on both sides with rubber, coal tar and natural bitumen.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Examination of anti-rust paint pigments and efficacy of pigments and varnish in rust prevention. P. HERRMAN. *Farbe u. Lack* 31, No. 3, 27 (1926).—A review of the report of the "Technical Research Council for the Underground Construction of Berlin," published in *Korrosion u. Metallschutz* 1, 80-4 (1925). A color film protects iron from rust as long as no water penetrates it. Measurement of water protection is made by elec. means with the aid of electrolytes, in that a current is set up when moisture reaches the iron. Under the conditions of the expt. clear linseed oil varnishes failed in 24 hrs.; linseed oil color films protected the metal one week. Varnishes contg. bodied oils

were more waterproof. China wood oil added to the linseed oil varnish increased the water resistance considerably. Various pigments and the influence of particle size are considered.

Color styles for industrial buildings. WILH. SCHWIETE. *Chem.-Ztg.* 50, 20 (1926).—Commending "Fixil," a silicate paint, as suitable for use in industrial districts because of its resistance to weather, fumes, soap and water, sunlight, etc. R. J. MOORE

Chemical colors. SEVIER BONNIE. *Drugs, Oils & Paints* 41, No. 10, 342 (1926).—An address. B. briefly reviews types and prepn. of paint pigments. R. J. MOORE

Determination of the covering power, density and granulation of paint pigments. W. REGLIN. *Z. angew. Chem.* 39, 334 5 (1926).—A paint film is coated upon gelatinized paper, this is placed upon a ground-glass plate over a box, 20 X 40 cm., in which is a 32-c. p. lamp. The whole is placed in a darkened room, and the light transmitted through the film is easily studied. This affords a means of comparing various pigments and vehicles, as well as detg. the most suitable method of applying the paint, or the type of brush to be used. Photographs of rust-proofing paint, green paint for Fe work and coal tar colors for masonry are shown. H. STÖERTZ

Phenol resins. OTTO BEHRENS. *Teer* 24, 129-30 (1926).—Mainly a reproduction of advertising matter. W. B. PLUMMER

The A B C of pyroxylin lacquer. F. W. FASIG. *Drugs, Oils & Paints* 41, No. 10, 337-40 (1925).—An address. R. J. MOORE

Natural and artificial resins. JOH. SCHEIBER. *Farbe u. Lack* 31, No. 7, 76; No. 8, 87; No. 9, 99; No. 10, 113 (1926).—A comprehensive review of production and chemistry of resins. R. J. MOORE

HENGST, GUIDO: **Rezepte und seltene Arbeitsweisen für Maler, Lackierer und Anstreicher.** Munich: G. D. W. Calley. 88 pp. R. M. 2 50.

Paint remover. S. ISHIZAMA. U. S. 1,577,824, March 23. A mixt. suitable for removing paint from automobiles comprises H₂O 1 125 gals., NaOH 1/2 lb., "lye" 1/2 lb., benzine 2 oz., 7% NH₃ soln. 2 1/2 oz., CHCl₃ 1 oz., lemon juice 2 oz. and corn starch 4 oz.

Luminous paint. SOC. LA LUMINESCENCE. Brit. 237,624, July 24, 1924. Luminous paint for making signs, etc. is applied to a backing of celluloid or other material which will remain inert to the constituents of the paint.

Enamel finish. G. J. NIKOLAS. U. S. 1,578,464, March 30. Lustrous particles such as bronze powder are set in a lacquer-like coating and in a similar overlying coating and an outer protecting layer covers these 2 layers.

Printing ink. J. H. CAUGHLAN. U. S. 1,578,582, March 30. Rosin 15 lbs., NaOH 2 1/2 lbs., and H₂O are boiled together and pptd. with a soln. of Al sulfate, thus forming Al resinate and gelatinous Al(OH)₃. This product is washed and ground while still wet with 24 lbs. of No. 00 lithographic varnish to produce a vehicle for printing inks.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Analysis of by-product fats. C. BERGELL. *Seifensieder Ztg.* 53, 153-4 (1926).—For purposes of standard methods of analysis for fats and oils B. proposes to distinguish sharply between ether exts. of fats before and after sapon., only the latter furnishing reliable results for total fat content. B. also cites a case in which by-product soy-bean oil yielded 90.4% by direct ether extn. and only 83.9% when the oil was boiled with acid before extn. with ether. P. ESCHER

Marine animal oils—sperm whale oil. EMILE ANDRÉ AND Mlle. TH. FRANCOIS. *Compt. rend.* 182, 497-9 (1926).—The characteristics of the fat obtained from the whale indicate that the fat is intermediate between the fats and waxes. It is a question whether these properties are characteristic of the whale oil itself or whether they are due to the cephalopods upon which it feeds. E. SCHERUBEL

Report of Color of Oil and Meal Committee, A. O. C. S. 1/24. DAVID WESSON. *J. Oil Fat Ind.* 1, 23-9(1925).—A study of the Lovibond and Eastman Colorimeters for the color grading of vegetable oils. H. S. BAILEY

Constituents of crude cottonseed oil. G. S. JAMIESON AND W. F. BAUGHMAN. *J. Oil Fat Ind.* 1, 30-4(1925).—Analysis of the acetone-insol. portion of settlings of crude cottonseed oil showed Cl 0.0, SiO_2 0.60, P_2O_5 6.14, SO_3 0.0, CaO 0.26, MgO 1.46, K_2O 1.79, Na_2O 0.33% and Fe trace. Some of the P and bases in the settlings are inorg. phosphates. A phosphatide related to vegetable lecithins was isolated in the form of its CdCl_2 salt from an alc. soln. of the settlings; this was sol. in Et_2O , m. $194-6^\circ$ with decompn. and contained 15.36% Cd , and 3.91% P . The phosphatide could be only partially extd. from crude oil by MeOH and was partly decomposed and extd. by H_2O at 55° . NaOH refining of crude oil removes almost all the P compds. H. S. B.

Ochna pulchra berries. A. W. FACER. *Rhodesia Agr. J.* 22, 566-72(1925).—The berries are borne abundantly once in 2 yrs. on large trees, which grow well on poor soil. The oil derived from them is considered to be as good or better than peanut or cotton seed oils for most purposes. They contd. 8.4% H_2O and 32.9% oil. Constants for the kernel, pericarp and whole berry oil are given. Those for the latter are $d_{4^\circ}^{25}$ 0.9121, m. p. $22.5-25.5^\circ$, acid value 13.8, sapon. no. 199.7, I no. 67, titer 41.4° . The expressed cake contd. H_2O 10.0 protein 12.65, oil 7.0, carbohydrates 58.0, fiber 9.8 and ash 2.55%. A. L. MEHRING

Method for the direct identification of rapeseed oil by isolation of erucic acid. A. W. THOMAS AND MORRIS MATTIKOW. *J. Am. Chem. Soc.* 48, 968-81(1926).—The soly. (and in some cases the d. of the soln.) of stearic, behenic and erucic acids and Mg erucate in EtOH and H_2O and of Pb erucate in Et_2O is reported; the acids were detd. at 0° and 10° ; the salts at 25° . These results indicate a satisfactory sepn. of the Mg erucate from other unsatd. Mg soaps and also the unreliability of anhyd. Et_2O as a solvent. There is but slight loss of Mg erucate in the presence of large amts. of stearic acid (96% recovery) but with equal amts. of erucic and oleic acids less than 50% of the calcd. amt. of erucic acid was recovered as the Mg salt. The complete sepn. of Mg erucate depends upon the time of cooling (not more than 24 hrs.), the amt. of available $\text{Mg}(\text{OAc})_2$ present in soln. (25 cc. of 0.81 M $\text{EtOH-Mg}(\text{OAc})_2$ per 10 g. oil) and the amt. of EtOH necessary to wash the insol. soaps. The catalytic reduction of erucic acid to behenic acid is discussed. The technic of the proposed quant. method for the sepn. of erucic acid is given in detail, by which method from 42.7 to 48.2% erucic acid were isolated from various samples of rapeseed oil; if an oil be analyzed by the proposed method and an acid product weighing about 44% and having a m. p. of about 26° , and I no. of about 73, a mol. wt. of 336, then the oil may be said to be a genuine, pure, refined rapeseed oil. Catalytic reduction should yield an acid product, to the extent of 35% of the amt. of the oil, m. $77-79^\circ$ after 2 fractional crystns. The method is applied to mixts. of rapeseed-olive and rapeseed-cotton-seed oils. The acid does not distinguish rapeseed from mustard seed oil, since both yield a large proportion of erucic acid. C. J. WEST

A study of activated fuller's earth. O. ECKART. *Z. angew. Chem.* 39, 332-4 (1926).—Activated earths increase the free fatty acid of vegetable and animal oils exposed to their decolorizing action. This cannot be remedied by washing, and neutralization with alkali reduces the bleaching power of the earths, in consequence of a reduction of the effective surface by the pptn. on it of Fe and Al hydrates. Addition of CaCO_3 and $\text{Ca}(\text{OH})_2$ somewhat decreases the acidifying action. By heating the earths up to 450° , to drive out all the H_2O , the bleaching effect is reduced only about 10%, but the acidifying action is considerably reduced. Thus soy-bean oil, which shows an acid no. of 0.2 before decolorization, when treated with an earth dried in the air, shows an acid no. of 0.39 after treatment, while an earth heated at 450° gave an acid no. of only 0.29. When heated above 500° the bleaching effect is much decreased. Complete decolorization is attained in 10-30 min. If the oils are in contact with the decolorizer longer than 30 min., they take up coloring matter again. H. STOBRTZ

The mechanical handling of palm-oil fruit. M. A. STIELTJES. *Bull. mat. grasses inst. colonial Marseille* 1925, 275-83. E. SCHERUBEL

Marseille soap perfumes—behavior of some chemical products and perfume essences in Marseille soap with a coconut oil base. G. DE BELSUNCE. *Bull. mat. grasses inst. colonial Marseille* 1925, 288-93.—Three tables giving organoleptic results of various perfumes are discussed. E. SCHERUBEL

Method for determining reaction velocity in the soap-boiling process. G. I. FINCH AND A. KARJYM. *J. Soc. Chem. Ind.* 45, 35-6T(1926).—The reaction mixt. sample is dild. with distd. H_2O to a definite vol., contg. 2-3% of sample, and 25 cc. satd. with

laCl, which grains out the soap and fat, leaving the free alkali in soln with the exception of that occluded by the grains. The mixt. is then titrated against standard acid with phenolphthalein. Near the end point some light petroleum is added to liberate the occluded alkali from the grains. The titration is then completed. The total alkali is obtained by titrating a sep. portion of the mixt. with methyl orange as indicator. The difference between the 2 readings gives the amt. of combined alkali and from the quantity required by the oil for complete sapon., the degree of sapon attained in the reaction mixt. can be calcd.

E. SCHERUBEL.

Stain-removing soaps. A. C. *Tiba* 4, 93, 95, 211-5 (1926) A no. of formulas are given.

A. PAPINEAU-COUTURE

Manufacture of scented soaps. COLOMBO. *Parfums de France* No 36, 38-47 Feb., 1926).—Descriptive.

A. PAPINEAU-COUTURE

The equilibria underlying the soap-boiling processes. The system potassium oleate-potassium chloride water. J. W. MCBAIN AND W. J. ELFORD *J. Chem. Soc.* 1926, 421-38; cf. *C. A.* 19, 2139. "The equil. between the various forms of a K soap are very similar to those for a Na soap. All the soap phases that exist in the 3-component system including salt are found in the simpler system, soap and water, where also their sep'n is spontaneous; that is, they 'salt out' in the absence of salt and may even be observed at room temp. The limits of the field of existence of isotropic liquid solns. of K oleate with and without KCl have been accurately detd. for temps. up to 210°. This single phase includes wholly crystalloidal solns. and ranges, at sufficiently high temps., from pure H₂O up to pure anhyd. liquid K oleate, the two being miscible in all proportions above 300°. Improvements in the methods of optical investigation have enabled progress to be made with the delimitation of the two important anisotropic liquids, neat soap and middle soap. Both neat soap and middle soap are typical conic anisotropic liquids."

F. L. BROWNE

The highest melting saturated acids of peanut oil (HOLDE, GODBOLE) 10.

Rendering animal fats. W. LAABS. U. S. 1,578,245, March 23. Material such as packing-house offal or garbage is heated at such low temps. and pressures as not to cause substantial disintegration, fats and oils are sep'd. before the H₂O content is reduced to 60% and the material is then disintegrated under steam pressure at temps. above 115° (the steam pressure being developed from the H₂O naturally present in the material). Disintegration is effected while the H₂O content is still above 17% and then, after further heating at subatm. pressure and at temps. below 115°, the solid residue is expressed to sep. residual fats and oils.

Purifying and decolorizing oils. H. I. KAUFFMAN. U. S. 1,579,326, April 6. The mineral leverrierite is used for treating oil after dissolving out acid sol. constituents associated with the mineral.

28--SUGAR, STARCH AND GUMS

F. W. ZERBAN

Sugar industry in western India. R. G. PADHYE. Dept. Agr., Bombay. Presidency. *Bull.* 116, 223 pp. (1924). A general discussion with comparative figures for other countries.

K. D. JACOB

Prevention of inversion in the sulfuring of raw juice. E. HADDON. *Intern. Sugar J.* 27, 445 (1925). It was pointed out by H. in 1904 that the glucose ratio of sulfured juices was always higher than that of unsulfured juices, which leaves no doubt as to inversion having taken place. In factories where the juices are first limed, then sulfured, the glucose ratio of the 2 juices remains the same, this being due to the neutralization of the H₂SO₄ which is gradually being formed by the oxidation of the H₂SO₄. On slightly limed cane juices 1% of SO₂ has no inverting action even at 50°. To prevent inversion in the factory it is only necessary to add some lime now and then to the sulfuring tank. Some destruction of sugar always results from heat when steam ejectors are used for drawing in air for combustion of the S and for forcing the acid into the juice. The only way to prevent this destruction is to isolate the top part of the Pb coil by means of a large cylinder of Pb, closed and soldered at the bottom to the coil.

J. S. JOFFE

Sucrose crystallization. I. A. KUKHARENKO. *Zapiski (Russian)* 1, 173-84 (1924).—To crystallize sucrose at high temp. it is rarely possible to avoid the formation of cracks. The heating has to be done gradually. In taking out the crystals from the hot environment to a cooler the crystals are damaged; they are covered with a layer of the soln. and the process of crystn. is continued under new conditions; the crystals become dull; difficulties are encountered in manipulating supersatd. solns. at high temp. The appearance of the soln. is not always a true guide; centers of crystn. may appear which are not noticeable to the observer; it is necessary to decrystallize the soln. For this purpose the soln. at this point is heated for $1\frac{1}{2}$ hour at a temp. 20-25° higher. In sampling there is danger of contaminating the soln. with crystals from the air.

PRINSEN-GEERLIGS, H. C.: Zuckerrohr. Hamburg: Deutscher Auslandverl. W. Bangert. 123 pp. R. M. 5.

Purifying sugar solutions. K. URBAN. U. S. 1,577,389, March 16. Sugar solns. are filtered through a mass of natural or artificial zeolites or similar base-exchanging material until the soln. is enriched with alk. earth substances and then further filtered through additional material to remove alk. earths and other ashy substances and org. non-sugars.

Electroosmotic purification of saccharine juices. K. WOLF and E. LANGSTEIN. U. S. 1,577,669, March 23. An aq. saccharine soln. is subjected to the action of an elec. current with the soln. sepd. from the electrodes by semi-permeable diaphragms. The anodic diaphragm is formed of leather impregnated with quinone and the cathodic diaphragm of sail cloth.

Filtering sugar solutions or other liquids. C. V. ZOUL. U. S. 1,579,171, March 30. Clean liquid such as filtered solution under treatment is repeatedly circulated through a filtering app., followed by a gradual addition of a filter aid, such as diatomaceous earth, to the circulating liquid to form a bed of the filter aid on the filtering surfaces of the app. previous to filtration of the liquid to be treated.

Recovering calcium hydroxide in sugar purification. G. M. DRUMMOND. U. S. 1,580,024, April 6. In recovery of Ca(OH)₂ from cold sucrate obtained in a process of recovering sugar from molasses in the manuf. of sugar from sugar beets, the liquid mixt. is continuously introduced into pressure or vacuum thickeners from which clear liquid continuously flows. The ppt. is removed from the bottom and subjected to filtration and the filtering medium in the thickener is kept completely submerged at all times.

Beet sugar. E. E. NICHOLSON and R. B. BEAL. U. S. 1,578,463, March 30. Beet juice is treated with an excess of caustic lime and Na aluminate or other H₂O-sol. aluminate is added to ppt. portions of the excess lime and other hydroxides present. Floccular and granular ppts. are formed, filtered out and the filtered soln. is treated with CO₂ and again filtered.

Sugar recovery from molasses. C. DROUIDE. U. S. 1,579,090, March 30. Org.

impurities contained in molasses and sugary juices are pptd. and destroyed by monopyritic silicate, preparatory to sucrose recovery.

Refining sugar. C. STEFFEN. Brit. 237,861, July 31, 1924. In washing tri-Ca ucrate on the filter after filtration, 1-2% of fine sawdust, well-washed satn sludge, sand, oal or kieselguhr or other finely divided readily filterable substances are added to the washing H_2O (with or without decolorizing substances) to prevent formation of cracks and facilitate uniform washing.

Desugaring "muds" of sugar recovery. R. VACHIER. U. S. 1,578,220, March 23. A partially exhausted "mud" is treated with fresh H_2O and with a quantity of lime sufficient to cause coagulation and ext. the sugar content of the "mud." A clear sweet water is thus produced for use in the milling process and the "mud" is substantially desugared.

Clarifier for sugar solutions. R. VACHIER. U. S. 1,578,221, March 23.

Preserving sugar. W. L. OWEN. U. S. 1,579,387, April 6. Raw or unrefined sugar is inoculated with a small proportion of torulae yeast.

Conversion products from starch. J. M. WIDMER. U. S. 1,578,568, March 30. Starch is converted with hydrolyzing acid to the glucose stage, the hydrolyzing acid is neutralized in the presence of H_3PO_4 , pptd. impurities are removed by filtration, the liquor is treated with tannic acid, filtered to remove coagulated albuminoids and insol. inorg. salts, and then treated with C to remove excess tannic acid and coloring substances.

29--LEATHER AND GLUE

ALLEN ROGERS

Properties of shoe leather. I. Micro-structure. J. A. WILSON AND GUIDO DAUB. *J. Am. Leather Chem. Assoc.* 21, 193-8 (1926).—Description of technic and full-page photomicrographs of typical samples of the following kinds of shoe leather: vegetable-tanned calf upper, chrome calf upper, glazed kid, kangaroo, cordovan, buck, chrome side, suede, calf lining, sheep lining, shark upper, patent side, patent kid, patent colt, heavy chrome upper, chrome-tan army upper, vegetable tanned sole, and chrome sole leathers. **II. Chemical composition.** J. A. WILSON AND GEO. O. LINES. *Ibid.* 198-206.—Chem. analyses of the 18 leathers whose photomicrographs are pictured in paper no. I of the series. J. A. WILSON.

A possible explanation of the antagonistic action of neutral salts upon hide substance. K. H. GUSTAVSON. *J. Am. Leather Chem. Assoc.* 21, 206-16 (1926).—Thomas and Foster (C. I. 20, 123) found that hide protein is hydrolyzed by chlorides and preserved by sulfates. Proteins may be broken upon as complex polypeptides held together by forces of secondary valence. Chlorides show a marked tendency to form addn. compds. with polypeptides. Decompn. of the protein and dispersion follow the switching of the secondary valency forces of the polypeptides from each other to the neutral chlorides. Different salts arranged in order of their tendency to form stable compds. with amino acids and polypeptides showed a similar order for protein decompn. in the work of T. and F. J. A. WILSON.

Tanning with vegetable tannin. PIERRE LABADIE. *La nature* 54, 1, 172-5 (1926).—An illustrated description of operations on a large scale. C. C. DAVIS.

Tannin plants of Maquilung region. AURELIANO J. VILLANEVA. *Philippine Agr.* 14, 569-79 (1926). The bark, leaves, roots and fruits of 81 plants, belonging to 30 families were tested for tannin. Members of 14 families contained tannin and the results are tabulated. Six references are given. A. I. MEHRING.

Adsorption. XII. Adsorption of tannin and quebracho tannides by skin. P. N. PAVLOV. *Kolloid Z.* 37, 215-21 (1925). The adsorption coeff. (cf. C. I. 10, 760) of tannin by skin which had been macerated and then pressed dry depends in a high degree upon the vol. of the bath and the mass of the adsorbent. This suggests a chem. reaction between the tannin and the skin. The variation from a direct proportionality between the adsorption coeff. and the vol. and an inverse proportionality between the adsorption coeff. and the mass of the adsorbent suggests that the chem. process is accompanied by a diffusion of the tannin into the skin and by a distribution of the tannin between the 2 phases. The adsorption coeff. of the quebracho tannides by skin similarly treated showed less dependence upon the vol. of the bath and the mass of the adsorbent. The chief process was not a chem. reaction between the skin and the tannides but a distribution of the tannides between the 2 phases. The presence of H ion in the skin or in the soln. considerably increased the adsorption of the tannide. H. M. McLAUGHLIN.

The recovery and use of waste products. IV. J. B. C. KERSHAW. *Ind. Chemist* 2, 122-6(1926).—Outlines are given of methods now in use and methods suggested for the disposal or working up of the various liquid and solid wastes from *tanneries* (cf. *C. A.* 20, 634, 955). E. G. R. ARDAGH

Use of aminohydroxysulfonic acids in the dyeing of skins. V. CASABURI. *Boll. ufficiale* 3, 61-9(1925); *Chimie et industrie* 15, 271(1926).—The mordanting of leather with Cr compds., alum, tannins or metallic salts for dyeing with basic dyes does not readily give even colors; moreover, the astringency of even the mildest tannins modifies the grain and interferes with proper finishing. "H acid" (1-amino-8-naphthol-3,6-disulfonic acid) easily combines with metallic hydroxides used as mordants and allows of applying them to leather without any of the above drawbacks. The following formulas are given: H acid 100, Na phosphate 10, Cr sulfate 6; H acid 100, Na_2CO_3 100, KMnO_4 20, NaHSO_4 20, Rochelle salt 20; H acid 100, Fe^{++} sulfate 87, Na acetate 40, Na_2CO_3 30, NaHSO_4 60; H acid 109, Cu sulfate 78, Na acetate 40, Na_2CO_3 30, NaHSO_4 60. A. PAPINEAU-COUTURE

Cementing and vulcanizing rubber and leather sheets together (U. S. pat. 1,577,349) 30.

LAMB, M. C.: **Die Chromlederfabrikation.** Berlin: J. Springer. 268 pp. R. M. 20.

Finishing leather. J. B. WELCH and W. C. WELCH. U. S. 1,579,264, April 6. Degreased leather is humidified to restore the degreasing shrinkage, a layer of coating material such as a "patent leather" compn. is applied to the leather and the coating is dried under conditions so regulated as to counteract the tendency of the leather to shrink during the drying.

Electrosmotic purification of glue and gelatin. W. RUPPEL and K. WOLF. U. S. 1,577,660, March 23. An aq. soln. of the material is subjected to an elec. current with the soln. spnd. from the electrodes by diaphragms. The anodic diaphragm is of wool fabric impregnated with chromated gelatin and the cathodic diaphragm is of parchment.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Synthetic rubbers. I. I. SLOIM. *Rev. gén. caoutchouc* 1926, No. 19, 69.—Historical. C. C. DAVIS

Notes from a pioneer on Indian rubber from the latex. HENRY WICKHAM. *Trans. Inst. Rubber Ind.* 1, 304-7(1926).—Historical. C. C. DAVIS

The spraying of latex. R. DITMAR. *Rev. gén. caoutchouc* 1926, No. 19, 13-4. A new app. is described which is adapted for the concn. of latex on a large scale. It is characterized by the use of a current of hot air, under pressure and of very high velocity, which comes in contact with a stream of latex and disperses the latter in an extremely fine spray. This spray is then mixed immediately with hot air, and the concd. latex subsequently recovered. The system is described in detail and illustrated. C. C. DAVIS

Remarks on the work of Dr. Ditmar on the concentration of latex. E. A. HAUSER. *Caoutchouc & gutta-percha* 23, 13,046(1926).—Comments on an article by Ditmar (*C. A.* 20, 1338). C. C. DAVIS

Deterioration with time of crude and of vulcanized rubber. A. CHERBULIER. *Recherches et inventions* 6, 877-80(1925); 7, 102-7, 135-9(1926).—Critical review of the more important work published on the subject, with bibliography of 68 references. A. PAPINEAU-COUTURE

Factors influencing the plasticity of sole crepe (rubber). H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 716-22(1925).—The spread of crepe rubber soles is due to the plasticity induced by machining, which has been held to rupture the protein films surrounding the particles of the rubber hydrocarbon. The behavior of rambong (*Ficus elastica*) and *Castillou elastica* rubbers, the particles of which have no skin, makes this hypothesis doubtful. The method and results of plastometer tests are described. B. C. A.

Tendencies in rubber compounding. WM. B. WINGAND. *Trans. Inst. Rubber Ind.* 1, 141-76(1926).—More comprehensive than *C. A.* 20, 840. C. C. DAVIS

The calendar in the rubber industry. W. G. MARTIN. *Trans. Inst. Rubber Ind.* 1, 177-90(1926). C. C. DAVIS

A new method for determining the quality of raw rubber. W. GREINERT AND J. BEHRE. *Kautschuk* 1926, 29-31.—The method depends upon the fact that the better the rubber and the less plasticized it is, the less the capillary action shown by its dispersions. A strip of filter paper (Schleicher & Schull No. 597 is recommended) 0.5 cm. wide and 14 cm. long is clamped to a vertical glass scale so that about 1 cm. of the strip projects below the scale into a C_6H_6 soln. of the rubber (0.5 g. per 100 cc.). The scale must be safely above the liquid, and to avoid evapn. the scale and paper are put in a closed test tube. The most reliable results are obtained by measuring not the max. height to which the liquid ascends, but the rate of ascent compared to the rate for the solvent alone. Readings may be taken each min. for 10 min. and the height plotted against the time. The rates are such that when plotted logarithmically, straight lines are obtained. The method not only shows clearly the differences between various types of rubber, but also reveals the progressive changes taking place when rubber is plasticized. In tests with different rubbers, the rate of capillary ascent of the liquid was slowest for first latex crepe and increased in the order: smoked sheets (highest quality), unsmoked sheets, *Ficus* crepe, guayule (Duro), light brown remilled crepe (native), C_6H_6 alone. The wide differences in rate are shown by the fact that after 10 min. the heights in mm. were approx. 7, 19, 21, 32, 48, 50, 100, resp. for the C_6H_6 in the order above. Increasing plasticity due to milling also manifests itself by a progressively increasing rate of capillary ascent. Based on the changes in rate, smoked sheets which were milled for 80 min. showed a relatively great change after the first 5 min., the changes being relatively small thereafter, and becoming progressively smaller. C. C. DAVIS

Research work on the plantations. B. J. EATON. *Trans. Inst. Rubber Ind.* 1, 112-22 (1925).—An English version of C. A. 19, 1962. C. C. DAVIS

Sulfur. EDWARD ANDERSON. *Trans. Inst. Rubber Ind.* 1, 171-6 (1925). See C. A. 19, 908. C. C. DAVIS

Gutta-percha. Its preparation and general properties. C. W. H. HOWSON. *Trans. Inst. Rubber Ind.* 1, 36-54 (1925).—See C. A. 19, 908. C. C. DAVIS

Influence of the fineness [of rubber] on the time of acetone extraction. SR. REINER. *Kautschuk* 1926, No. 1, 5-6.—Systematic expts. with fine Para rubber (unvulcanized) show that the time required for complete extn. of the Me_2CO -sol. resins depends upon the extent to which the rubber is subdivided for extn. Under the conditions used, which included agitation of the rubber, uniform distn. and condensation of Me_2CO and particles of rubber of 9 sizes from 6.8 to 18.1 mm. diam., the extn. was almost complete (2.49%) in 7 hrs. for the largest size and in 2 hrs. for the smallest size. Contrary to Spence and Scott (cf. C. A. 6, 430) moreover, there was no approach to "practical" extn. in 0.5 hr. The smallest size of particles gave 1.74% in 1 hr., 2.34% in 2 hrs. and 2.43% in 4 hrs. while the largest size gave 1.03% in 1 hr., 1.28% in 2 hrs., 1.63% in 3 hrs., 2.08% in 4 hrs., 2.28% in 6 hrs. and 2.12% in 7 hrs. Since the extn. was continuous rather than intermittent as with zeolite and H_2O (cf. Weigel and Steinhoff, *Z. Krist.* 61, No. 1, 2 (1925)) and since the process is irreversible, the resin is probably combined intramolecularly or additively and is not merely adsorbed by the rubber. Since rubber can adsorb large vols. of vapors and gases, the extn. may also be an exchange by the rubber resin for Me_2CO and not simply removal of the resin because of its soln. in Me_2CO . The results also indicate that by agitation of the rubber, the 8-10 hrs. usually prescribed for extn. may be reduced in technical work. C. C. DAVIS

Sodium fluosilicate as a coagulant. J. EDWARDS. *Bull. Rubber Growers' Assoc.* 8, 34-6 (1926), cf. C. A. 20, 511. Although *p*-nitrophenol enhanced the violet coloration to which the H_2OAc coagula from some samples of latex are liable, no such coloration took place in Na_2SiF_6 -coagula, with or without *p*-nitrophenol. Na_2SiF_6 prevented the formation of bubbles in smoked sheet. F. H. YORSTON

Sulfuric acid-rubbers. F. KIRCHHOFF. *Kautschuk* 1926, No. 1, 1-4.—A comprehensive review and discussion of earlier work by K. (C. A. 15, 960, 16, 1885, 17, 3112, 19, 2758). Work in progress on the action of concd. H_2SO_4 on latex is also described in a preliminary way. The product differs from that obtained from rubber in org. solvents, is yellowish white and crumbly and is converted to a tough mass by treatment with warm Me_2CO . It swells greatly in xylene and on prolonged boiling the greater part dissolves. On evapn. this soln. yields a tough yellowish brown, transparent mass, which has but little elasticity and tackiness and somewhat resembles synthetic dimethyl rubber. It fuses to a black pitch having when cold a lustrous fracture. With S_2Cl_2 the xylene soln. yields a stiff but fragile gel, which differs therefore from cold-vulcanized rubber. It is probable that the action of S_2Cl_2 on latex does not progress.

so far as its action on rubber in org. solvents, and it is possible that only the outer layer of the latex particles is attacked. The unchanged inner portion thus dissolves in boiling xylene. The product of the action of H_2SO_4 on latex has a potential value technically.

The acceleration of vulcanization by alkaloids. B. J. EATON AND R. O. BISHOP. *Malayan Agr. J.* 14, 8-12(1926).—In view of the accelerating action of the alkaloids of cinchona bark (cf. C. A. 17, 1350), 3 other alkaloids were tested for their activity. Cocaine, nicotine and hyoscyne failed to accelerate the cure of rubber-S (90:10) mixts. but emetine had a marked accelerating power even in very small amts., the optimum cure being reduced almost to $1/4$ its original time by the addn. of 0.0081%. This activity was further enhanced by the addn. of ZnO. Only small amts. of the alkaloids were used in the expts., the max. % of cocaine, nicotine, hyoscyne and emetine tested being 0.1, 0.45, 0.075 and 0.05. Since *Ipecacuanha* root and root bark contain these alkaloids, the attempt was made to utilize the accelerating action of the finely ground root and bark as a criterion of their value with respect to their alkaloid content. Though in general the rate of cure increased with the amt. of active alkaloid added by means of the root, no definite relation could be ascertained.

Investigations of native rubber. W. SPOON. *Arch. Rubbercultuur* 10, 29-83, 84-106(1926).—(In English). About 250 samples of native rubber from 6 residences of the Dutch East Indies were examd. Most of the samples were slabs which contd. 10-50% H_2O and frequently 10% earth and bark shavings. Adulteration with Jelutong rubber was detected in a few cases. The time of cure, the tensile strength and the viscosity of 96 crepes prepd. from the slabs were very similar to those previously found for fewer samples (cf. C. A. 19, 3035). Detailed information concerning the source, appearance and properties of the rubber is given.

F. H. YORSTON

Coagulation and mold prevention of smoked sheet rubber. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 8, 36-40(1926); cf. C. A. 20, 125, 311.—Vulcanization tests of rubber coagulated with $HOAc$ or Na_2SiF_6 , alone or with dinitrophenol or *p*-nitrophenol. The acceleration of vulcanization due to the latter partly compensates for the retardation due to the Na_2SiF_6 .

F. H. YORSTON

Crepe rubber prepared with different reagents. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 8, 77-9(1926).—Expts. with crepe similar to those reported in the preceding abstract.

F. H. YORSTON

The influence of disinfectants on the coagulation phenomena in Hevea latex. O. DE VRIES AND N. BEUMÉE-NIEUWLAND. *Mededeelingen van het Centraal Rubberstation* No. 48; *Gummi-Ztg.* 40, 1255-6(1926).—An abridged version of C. A. 20, 676.

C. C. DAVIS

The isoelectric theory [coagulation of latex] (HARDY) 15.

CHAPLET, A.: *Manuel de l'industrie du caoutchouc*. Paris, J. B. Baillière et Fils. 247 pp. Reviewed in *Rev. chim. ind.* 35, 97(1926).

Vulcanizing rubber. D. N. SHAW. U. S. 1,580,089, April 6. Rubber is mixed with a vulcanizing agent such as S, incorporated with a nitrocarbazole and with an activator such as ZnO or PbO and the mixt. is heated.

Lining pipes with rubber. C. C. LOOMIS and H. E. STUMP. U. S. 1,576,767, March 16. Pipes of water systems or for other purposes are coated internally with latex and the coating is coagulated, e. g., by blowing air through the pipes.

Dipped seamless rubber goods. G. VENOSTA. U. S. 1,579,169, March 30. A suitable former is dipped in latex to which S and a metallic oxide have been added, the H_2O present is evapd., an accelerator is introduced into the film thus obtained by absorption and vulcanization is effected.

Rubber composition. W. B. WEGAND. U. S. 1,578,875, March 30. A compn. adapted for making shoe soles, etc., is formed by mixing rubber with 60-100% its wt. of C or lampblack and with vulcanizing agents.

Rubber composition. M. M. HAW. U. S. 1,578,121, March 23. In forming shoe heels or other articles, rubber is slowly mixed with pulverized hard stone to coat the particles of stone with the rubber. Additional rubber is then incorporated with the mixt. together with substances for promoting vulcanization.

Cementing and vulcanizing rubber and leather sheets together. A. L. MURRAY. U. S. 1,577,849, March 16.

Wall covering of sheet rubber containing cotton threads. J. H. STEDMAN. U. S.
